Cooper, Wm., Public Analyst's Laboratory, 67, Surrey Street, Sheffield, Analytical Chemist.

Craven, John I., 15, Hutchinson Street, Winthrop, Mass., U.S.A., Chemist and Salesman.

Davis, V. P., Naugatuck, Conn., U.S.A., Chemist.

Dobson, S., 22, Dangan Road, Cambridge Park, Wanstead, N.E., Paint Works Manager.

Dushman, Saul, School of Practical Science, Toronto, Canada, Electro-Chemist.

Friend, G. Clausen, c/o The D.B. Martin Co., Claremont, Baltimore, Md., U.S.A., Chemist.

Fuchs, Herman C., 83, Marlborough Road, Brooklyn, N.Y., U.S.A., Dry Colour Chemist.

Gaunt, Percy, Norman Road, Rusholme, Manchester, Chemist.

Gerkensmeyer, H. H., 109, South Eastern Avenue, Joliet, Ill., U.S.A., Chemist.

Gorrie, David, c/o D. Gorrie & Son, South Methven Street, Perth, N.B., Engineer.

Green, Ernest, 113, Hulton Street, Moss Side, Manchester, Science Teacher.

Hanfeld, Fred. C., 5, West 95th Street, New York City, U.S.A., Wall Paper Manufacturer.

Haskell, Walter F., 234, Bridge Street, Westbrook, Maine, U.S.A., Textile Chemist and Colourist.

Herty, Prof. Chas. H., University of North Carolina, Chapel Hill, N.C., U.S.A., Professor of Chemistry.

Hoyler, Fritz, 49, Market Street, Perth Amboy, N.J., U.S.A., Chemist.

Ingalls, Robert C., 53, Commercial Street, West Lynn, Mass., U.S.A., Sales Manager, Fine Chemicals.

Kirby, Oswald F., The Leeds Institute, Leeds, Lecturer on Chemistry.

Knapp, Walter R., c/o Semet-Solvay Co., Ensley, Ala., U.S.A., Chemist.

Macdougald, G. D., City Laboratory, 13, Shore Terrace, Dundee, City Analyst.

McDowell, Alex. H., c/o General Chemical Co., Bayonne, N.J., U.S.A., Chemist.

McGregor, Russell, Public Analyst's Laboratory, 67, Surrey Street, Sheffield, Analytical Chemist.

Mason, Frederic S., 54, Rue Rennequin, Paris, France, Manufacturing Chemist.

Massa, Corradino, Castelguelfo Parmense, Parma, Italy, Sulphuric Acid and Manure Maker.

Mills, W. H., Northern Polytechnic Institute, Holloway, London, N., Lecturer on Chemistry.

Murphy, Fred. W., Standard Sugar Refinery, Granite Street, South Boston, Mass., U.S.A., Chemist.

Myles, C. D., 16, St. Loo Mansions, Cheyne Gardens, London, S.W.

Nathan, Albert, c/o Warfield & Duell, 220, Broadway, New York City, U.S.A., Patent Lawyer.

Nestell, Raymond J., 115, West 68th Street, New York City, U.S.A., Instructor in Analytical Chemistry.

O'Brien, John W., c/o Grasselli Chemical Co., Grasselli, Lake Co., Ind., U.S.A., Acid Manufacturer.

Ogilvie, Alex. M., 7, Millbrae Crescent, Langside, Glasgow.

Parke, Jas., School of Practical Science, Toronto, Canada, Chemist.

Rossi, A. J., c/o Roessler & Hasslacher Chem. Co., Perth Amboy, N.J., U.S.A., Mining Engineer.

Rossi, L. M., Perth Amboy Chem. Works, Perth Amboy, N.J., U.S.A., Mining Engineer.

Schneible, Joseph, 14th Floor, Rector Building, Chicago, Ill., U.S.A., Chemical Engineer.

Schroeder, C. M. E., 221, Pearl Street, New York City, U.S.A., Analytical Chemist.

Scott, Arthur P., c/o Dominion Iron and Steel Co., Sydney, Cape Breton, Canada, Chemist.

Seiter, F. J., 3401, Charlton Street, Chicago, Ill., U.S.A., Chemist.

Small, Frank E., Foyle Villa, Merton Road, Bootle, Liverpool, Works Chemist.

Smith, Arthur D., 91, Avenue C., Bayonne, N.J., U.S.A., Chemist.

Smith, Arthur G., Washington Portland Cement Co., Baker, Wash., U.S.A., Chief Chemist.

Smith, Robert C., 425, Home Avenue, Oak Park, Ill., U.S.A., Chemical Engineer.

Stickland, Oliver W., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Works Chemist.

Straus, Louis, 18, West 83rd Street, New York City, U.S.A., Merchant.

Symes, Langford P., Parcora Freezing Works, Timaru, N.Z., Chemist.

Tempany, H. A., Government Laboratory, St. John's, Antigua, West Indies, Analyst.

Tolman, Frank S., 451, State Street, Flushing, N.Y., U.S.A., Superintendent (Oakes Manufacturing Co.).

Warwick, Philip H., c/o Messrs. J. Richardson & Son, Millgate, Newark-on-Trent, Maltster.

Webb, Frank H., P.O. Box 104, Apponang, R.I., U.S.A., Chemist.

Weiss, Philip, jun., Wharton Furnaces, Wharton, N.J., U.S.A., Chemist.

Wheeler, Frank G., Trenton, Mich., U.S.A., Chemist.

Wilke, Wm., 86, Norwood Avenue, Buffalo, N.Y., U.S.A., Chemical Engineer.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Allen, Charles A., l/o Irlams; 188, Harwood Street, Darwen, Lancashire.

Baron, W. Briscoe, l/o Manchester; c/o Jos. Crosfield & Sons, Ltd., Warrington.

Bartripp, G. F.; all communications to 51, Pulteney Road, South Woodford.

Bielecki, Dr. Jan, l/o Marzalkowska; 66, Krakowski Przedmiescie, Warsaw.

Bond, Josiah, l/o Somerville; Patagonia, Arizona, U.S.A.

Braman, W. W.; all communications to Box 353, State College, Pa., U.S.A.

Bruce, Jas., l/o Belfast; Craik, Saskatchewan, Canada.

Buchanan, E. F., l/o Akron; Nürnbergerstrasse 3, Berlin, W., Germany.

Burnside, C. F., l/o Parlin; California Powder Works, Santa Cruz, Cal., U.S.A.

Carter, Stewart F.; Journals to Park Place, Suffern, N.Y., U.S.A., Superintending Chemist.

Charlton, Thos., l/o San Francisco; 325, Irvington Place, Denver, Colo., U.S.A.

Chilwell, John, l/o Wednesbury; Post Office, Auckland, New Zealand.

Collingridge, Frank, l/o Beaufort Road; 73, Fountain Road, Edgbaston.
Crighton, W. H., l/o Newington Green; 33, Ardleigh Road, Southgate Road, London, N.
Davis, Charles B.; all communications to c/o National Brewers' Academy, 402, West 23rd Street, New York City, U.S.A.
Davis, Emerson, l/o Cass Avenue; 30, Watson Street, Detroit, Mich., U.S.A.
De Blois, W. H., l/o Pulaski; c/o General Chemical Co., Hudson Heights, N.J., U.S.A.
Edgerley, D. W., l/o New York; c/o The Chilton Paint Co., 120, High Street, Boston, Mass., U.S.A.
Fudge, Thos., l/o 397; 604, Avenue E., Bayonne, N.J., U.S.A.
Goodchild, W. H., l/o Borneo; Elmwood Lodge, Long Lane, Finchley, N.
Hammersley, W. S., l/o Longjumeau; 15, Rue des Carriers, Soignies, Belgium.
Hasting, J. J., l/o Water Street; c/o Louis Leavitt, North 11th Street and Driggs Avenue, Brooklyn, N.Y., U.S.A.
Humphrey, R. L., l/o Philadelphia; U.S. Geological Survey, Exposition Grounds, St. Louis, Mo., U.S.A.
Johnson, Edw., l/o Rua do Commercio; c/o Herdeiros Bowman, Ltd., Caixa 57, Pernambuco, Brazil.
Johnson, F. M. G.; communications to University College, London, W.C.; Journals as before.
Krause, Dr. G.; Journals to Verlag der Chemiker Zeitung, c/o Otto von Halem, Cöthen, Anhalt, Germany.
Lane, Fred H., l/o Park Place; 418, Sackett Street, Brooklyn, N.Y., U.S.A.
Le Maistre, F. J., l/o Philadelphia; Eastern Laboratory, Chester, Pa., U.S.A., Research Chemist.
Levy, Arthur G., l/o Maida Vale; 45, Clifton Hill, Abbey Road, London, N.W.
Main, Wm., l/o Brooklyn; Piermont, N.Y., U.S.A., Chemist.
Mardick, Jno. R., l/o Du Bois; Westminster, Md., U.S.A.
Masujima, Prof. B., l/o 19; 23, Midoricho-Itchome, Honjoku, Tokyo, Japan.
Maxim, Hudson, l/o Sterling Place; 698, St. Mark's Avenue, Brooklyn, N.Y., U.S.A.
Mellen, E. D., l/o Curtis, Davis & Co.; President (Pilot Range Mining Co.); Journals to Cambridge, Mass., as before.
Mercer, C. A.; all communications to 34, Camomile Street, London, E.C.
Milroy, Andrew; all communications to 48, Dinmont Road, Shawlands, Glasgow.
Morris, Harry, l/o Avenue House; The Hall, Hexthorpe, Doncaster.
Munton, Fred. T., l/o Runcorn; The Oak House, Winsford, Cheshire.
Neave, Geo. B., l/o George Street; Technical College, Montrose Street, Glasgow.
Neech, Herbert R.; l/o Huelva; St. Catherine's, Lincoln.
Paine, Augustus G., l/o Times Building; 41, Park Row, New York City, U.S.A.
Palmenburg, O. W., l/o West 70th Street; 80, St. Nicholas Avenue, New York City, U.S.A.
Park, James, l/o 51; Hillside House, 42, Millburn Street, Glasgow.
Parker, Charles E., l/o New Brunswick; 1361, Fairmont Street, Washington, D.C., U.S.A.
Pettit, Alf., l/o Glenwood Road; 375, State Street, Brooklyn, N.Y., U.S.A.
Pierce, Ira L., l/o Atlantic Manufacturing Co.; c/o Eastern Dynamite Co., Barksdale Plant, Washburn, Wis., U.S.A., Superintendent.
Saxe, Sigmund, l/o New York City; Bradford, Pa., U.S.A.
Sisson, George, jun., l/o Washington; 13, Grey Street, Newcastle-on-Tyne, Technical Chemist.
Strayer, D. W.; all communications to c/o Oxford Copper Co., Camden Works, corner State and Tenth Streets, Camden, N.J., U.S.A.
Swindells, Seth, l/o Scholar Green; Holly Villas, Lawton, Stoke-on-Trent.
Tobey, C. R.; Journals to Burks Falls, Ont.; and (subscriptions) Collingwood, Ontario, Canada.
Tufts, C. G., l/o Syracuse; c/o Solvay Process Co., Detroit, Mich., U.S.A.
Van der Linde, Harold; all communications to 101, Tyndall Avenue, Toronto, Canada.
Vogel, G. C., l/o Cass Street; c/o Pfister and Vogel Leather Co. (Journals) Milwaukee, Wis., U.S.A., and (subscriptions) 18 Market Street, Bermondsey, S.E.
Walker, Dr. Wm. H.; Journals to Massachusetts Institute of Technology, Boston, Mass., U.S.A.
Watt, H. E., l/o Dartford; 226, Ladywood Road, Birmingham.
Watson, John C.; The Bleachery, Saylesville (not Taylersville), R.I., U.S.A.
Whowell, Fred., l/o Bolton; Croich Hey, Tottington, Bury, Lancashire.
Woodward, Horace A.; Journals to 1268, Amsterdam Avenue, New York City, U.S.A.
Zimmele, H. B., l/o Howe Street; 200, Bellfield Avenue, Pittsburg, Pa., U.S.A.

Deaths.

Bardsley, Robt., Messrs. Jowsbury and Brown, Manchester. Feb. 20.
Clark, Augustus, Fundicio do Bowman, Pernambuco, Brazil.
Hurst, G. H., 22, Blackfriars Street, Salford. Feb. 5.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (1) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 2316. Renshaw. Tank wagons for transporting petroleum, naphtha and other liquids. Jan. 30.
" 2419. Critien. *See under* XVIIIB.
" 2535. Soc. C. et G. Grimmeisen. Cooling apparatus. [Fr. Appl., Feb. 3, 1905.]* Feb. 1.
" 2591. Higginbottom. Washing, rinsing and whizzing granular matter, sugar, ores, minerals, and the like. Feb. 2.
" 2718. Brook. Furnaces. Feb. 3.
" 2755. Ruttkamp. Mixing machines.* Feb. 5.
" 2991. Boult (Goldman and Co.). Filters.* Feb. 7.
" 2992. Boult (Goldman and Co.). Filters.* Feb. 7.
" 3080. Politz. Furnaces.* Feb. 8.
" 3135. Kapf. Method of reducing organic or inorganic compounds.* Feb. 8.
" 3229. Dewrance. Filter presses. Feb. 9.
" 3240. Stoddart. Manufacture of filtering media from slag. Feb. 9.
[C.S.] 2097 (1906). Stocker. Drying various substances, such as clay. Feb. 7.
" 2102 (1905). Stocker. *See under* IX.
" 2520 (1905). Fieldhouse. Tanks for producing a liquid free from suspended solids. Feb. 14.
" 5668 (1905). Spooner (Cie. pour la Fabr. des Compteurs et Matérial d'Usines à Gaz). Apparatus for measuring high temperatures. Feb. 14.
" 7961 (1905). Lennox and Mackenzie. Means for evaporating liquids and concentrating the solids in the same. Feb. 14.
" 7962 (1905). Lennox and Mackenzie. Evaporators for evaporating the liquid in brewers' wash, spent wash or pot ale, waste or spent dyes, &c., and concentrating the solids in the same. Feb. 14.
" 8342 (1905). Lennox and Mackenzie. Evaporators for evaporating the liquid in brewers' wash, spent wash or pot ale, waste or spent dyes and the like. Feb. 7.
" 19,277 (1905). Spooner (Aktiebolaget Separator). Centrifugal separators. Feb. 14.
" 26,622 (1905). Dickins. Combined measuring glass and pestle and mortar. Feb. 7.

II.—FUEL, GAS, AND LIGHT.

[A.] 2213. Goodwin. Suction gas producers. Jan. 29.
" 2245. Hoering and Wielandt. Gasifying raw combustible materials.* Jan. 29.
" 2250. Simpson. *See under* X.
" 2368. Tully and Shadbolt. Apparatus for the manufacture of gas. Jan. 30.
" 2437. Zerning. Manufacture of filaments for incandescent lamps.* Jan. 31.
" 2440. Hugershoff. Carburetting apparatus.* Jan. 31.
" 2498. Milne. Manufacture of gas for illuminating, heating and power purposes. Feb. 1.
" 2554. Zerning. Manufacture of filaments for electric incandescent lamps.* Feb. 1.
" 2831. Spieske. Heat storing compound. Feb. 5.
" 2907. Wilton. Purification of gases produced in the destructive distillation of coal or other carbonaceous substances.* Feb. 6.
" 2929. Sims and Bowes. *See under* VII.
" 3003. Stuart-Bailey. Coking coal and ovens therefor. Feb. 7.
" 3006. Winand. Production of a working medium for internal combustion engines. [Ger. Appl., Feb. 8, 1905.]* Feb. 7.
" 3060. Griffin. Suction gas producers. Feb. 8.
" 3089. Jensen (Maemecke). Thermic mixtures.* Feb. 8.
" 3145. Streubel. Incandescent mantles. [Ger. Appl., March 24, 1905.]* Feb. 8.
" 3213. Just, Hanaman, Landesberger, Salzmann, and Verein. Elektricitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. Feb. 9.
" 3225. Just, Hanaman, Landesberger, Salzmann, and Verein. Electricitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. Feb. 9.
" 3339. Clama. Manufacture of oil gas and apparatus therefor. Feb. 10.
[C.S.] 5008 (1905). Bowman and Southworth. Gas producers. Feb. 7.
" 10,496 (1905). Lane. Gas producers. Feb. 14.
" 18,403 (1905). Siemens und Halske A.-G. Incandescence bodies of tantalum wire for electric glow lamps. Feb. 7.
" 24,137 (1905). Dürr and Hudler. *See under* XXIII.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 2269. Wynne. Purifying hydrocarbon oils. Jan. 30.
" 2316. Renshaw. *See under* I.
" 2606. Lockwood. Process for incorporating mineral oils with saponaceous or saponified materials. Feb. 2.
" 2680. Crowley and Payne. Lubricating oil.* Feb. 3.
" 2907. Wilton. *See under* II.
" 3192. Wetter (Rud-Rütgers Chem. Fabrik. f. Theerprodukte). Manufacture of pitch from tar. Feb. 9.
[C.S.] 11,191 (1905). Braschler-Kurtz. Method of treating bituminous substances, resins, oils, waxes, &c. Feb. 7.
" 21,518 (1905). Roth. *See under* XXIII.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 2622. Imray (Meister, Lucius und Brüning). Manufacture of yellow azo dyestuffs. Feb. 2.
" 2797. Imray (Meister, Lucius und Brüning). Manufacture of pure bordeaux-red sulphurised dyestuffs. Feb. 5.
[A.] 2927. Belart. Manufacture of synthetic indigo and other products formed by condensation. Feb. 7.
" 3107. Lerman, Schwartz and Pikos. Manufacture of a black dye with by-products including a tanning agent or a second black dye.* Feb. 8.
" 3341. Imray (Basle Chemical Works). *See under* V.
[C.S.] 15,170 (1905). Abel (Act.-Ges. f. Anilinfabr.). *See under* XIIIA.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 2220. Zillessen. Apparatus for dyeing fabric.* Jan. 29.
" 2330. Summers. Preparation of vegetable fibre.* Jan. 30.
" 2359. Lorrain (Schmid). Process for simultaneously ungumming and dyeing raw natural silk.* Jan. 30.
" 2720. Selbach. Method of printing books, calico and the like.* Feb. 3.
" 2830. Simon and Weckerlin. Process and apparatus for steaming fibres and fabrics. [Fr. Appl., May 22, 1905.]* Feb. 5.
" 2906. Bousfield (Soc. Anon. Fabr. de Soie Artificielle de Tubize). Manufacture of artificial silk and apparatus therefor. Feb. 6.
" 2939. Wilson. Reproduction of designs or the like on textile or other fabrics or substances. Feb. 7.
" 3025. Bousfield (Soc. Anon. Fabr. de Soie Artificielle de Tubize). Manufacture of artificial silk. Feb. 7.
" 3194. Wansleben. Machines for dyeing bobbins and the like. [Ger. Appl., March 1, 1905.]* Feb. 9.
" 3222. Imray (Meister, Lucius und Brüning). Manufacture of formaldehyde sulphoxylate. Feb. 9.
" 3341. Imray (Basle Chemical Works). Production of black to brown disazo dyestuffs on wool fibre. Feb. 10.
[C.S.] 5214 (1905). Lilienfeld and Tedesko. *See under* XIX.
" 7962 (1905). Lennox and Mackenzie. *See under* I.
" 8342 (1905). Lennox and Mackenzie. *See under* I.
" 10,195 (1905). Imray (Meister, Lucius und Brüning). Production of shaded effects on fabrics by padding. Feb. 14.
" 10,347 (1905). Page. Washing machines. Feb. 14.
" 12,650 (1905). Knopf, and Bremer Baumwollwerke C. Knopf und Co. Process and apparatus for treating cotton-seed hulls or other waste products containing fibrous materials. Feb. 7.
" 15,029 (1905). Dietl. Manufacture of artificial silk. Feb. 7.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

[A.] 2998. Martinet and Dulac. Apparatus for dyeing hides and skins.* Feb. 7.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 2442. Stoneham and Pearson. Manufacture of ammonia. Jan. 31.
" 2450. Elworthy. Process for solidifying carbonic acid and apparatus therefor. [Fr. Appl., Jan. 31, 1905.]* Jan. 31.
" 2466. Hermite. Method and apparatus for obtaining saturated solutions of salts. Jan. 31.
" 2506. King's Norton Metal Co., Ltd., Bayliss, Brownsdon and Smith. Solvent for lead and alloys of lead. Feb. 1.

[A.] 2531. Read. Treatment of minerals or compounds of the alkaline earth metals. Feb. 1.
„ 2619. Ogle and Carson. Production of zinc and other oxides. Feb. 2.
„ 2708. Tchernisc. Manufacture of sulphocyanides.* Feb. 3.
„ 2802. Küsel, and Deutsche Solvay-werke, A.-G. Electrolytic manufacture of salts of oxy-acids of halogens. Feb. 5.
„ 2823. Teichner and Askenasy. Process for electrolytically producing persulphates.* Feb. 5.
„ 2929. Sims and Bowes. Recovery of cyanogen compounds from crude gases and from by-products in the manufacture of cyanides.* Feb. 7.
„ 2960. Böhm. Manufacture of ozone. Feb. 7.
„ 3121. Winand. Production of oxygen for internal combustion motors. [Ger. Appl., Feb. 9, 1905.]* Feb. 8.
„ 3122. Chem. Fabrik Rhenania, and Projahn. Process for obtaining sulphur from sulphuretted hydrogen or gaseous mixtures containing the same.* Feb. 8.
[C.S.] 4334 (1905). Sanders. *See under* X.
„ 20,454 (1905). Reaney. Process of hydrating lime. Feb. 14.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 2879 (Chambers. Apparatus for drawing glass. [U.S. Appl., Feb. 15, 1905.]* Feb. 6.
[C.S.] 17,890 (1905). Seaboldt. Process of treating siloxicon. Jan. 24.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 2207. Boult (Cöln-Müsener Bergwerks Aktien-Verein). Manufacture of artificial stone, blocks, pipes and briquettes from slag.* Jan. 29.
„ 2260. Johnson. Plaster for walls. Jan. 30.
„ 2345. Kelly. Heat insulating materials.* Jan. 30.
„ 2685. Winstanley. Manufacture of artificial building blocks. Feb. 3.
„ 2878. Ford. Manufacture of artificial stone or sand lime bricks. Feb. 6.
„ 3014. Thom. Artificial stone. Feb. 8.
„ 3182. Alexander-Katz. Process of manufacturing artificial stone. [Ger. Appl., Sept. 22, 1905.]* Feb. 9.
„ 3344. Connolly. Material for coating metal and other surfaces.* Feb. 10.
„ 3345. Connolly. Manufacture of insulating material.* Feb. 10.
[C.S.] 2097 (1905). Stocker. *See under* I.
„ 2102 (1905). Stocker. Drying of clays and other materials. Feb. 14.

X.—METALLURGY.

[A.] 2201. Cowper-Coles. *See under* XI.
„ 2250. Simpson. Process of treating coke, ores, minerals and mineral products. Jan. 29.
„ 2476. Cowper-Coles. Process for blending and coating metals. Feb. 1.
„ 2506. King's Norton Metal Co., Ltd., Bayliss, Brownsdon and Smith. *See under* VII.
„ 2591. Higginbottom. *See under* I.
„ 2768. Mower and Bassett. Method and apparatus for condensing and collecting fumes from zinc and like furnaces. Feb. 5.
„ 2988. Newton (Westman Process Co.). Process of reducing iron ore.* Feb. 7.
„ 2989. Lafontaine. *See under* XI.
„ 3240. Stoddart. *See under* I.
„ 3252. Callmann and Bormann. Process of refining zinc and other metals. [Ger. Appl., March 20, 1905.]* Feb. 10.
„ 3318. Gutensohn. Treatment of slags for the recovery of metals. Feb. 10.
[C.S.] 3179 (1905). Soc. Anon. "La Neo-Metallurgie." Alloys. Feb. 7.
[C.S.] 4334 (1905). Sanders. Treatment of galvanisers' waste products for the recovery of metal and other substances. Feb. 14.
„ 6001 (1905). Anderson. Smelting ores, iron sand and the like, and subsequent conversion into steel or other metals or alloys. Feb. 7.
„ 7714 (1905). Elworthy and Williamson. Preparation of nickel. Feb. 14.
„ 13,626 (1905). Gebauer and Zenses. Restraining the ebullition of a blown charge of molten iron in a converter. Feb. 7.
„ 17,123 (1905). Hobson. Alloy. Feb. 14.
„ 19,941 (1905). Blood. Utilising iron ore waste in the manufacture of iron and steel. Feb. 14.
„ 22,932 (1905). Hamfeldt. Apparatus for disintegrating slag. Feb. 7.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 2201. Cowper-Coles. Process for coating and alloying one metal with another. Jan. 29.
„ 2456. Cowper-Coles. Electrolytic production of copper wire, strip, or the like. Jan. 31.
„ 2465. Hermite. Electrolytic apparatus. Jan. 31.
„ 2562. Betts. Electric furnaces.* Feb. 1.
„ 2691. Moseley. Electric heating, cooking and smelting. Feb. 3.
„ 2802. Küsel, and Deutsche Solvay-werke. *See under* VII.
„ 2823. Teichner and Askenasy. *See under* VII.
„ 2989. Lafontaine. Electrolytic process for extracting metals from their ores and treatment of copper waste for the recovery of pure copper.* Feb. 7.
„ 3004. Soc. Electro-Metall. Française. Electric mixing furnace. [Fr. Appl., Feb. 11, 1905.]* Feb. 7.
[C.S.] 4100 (1905). Thompson (Decker Manufg. Co.). Electrolytic apparatus. Feb. 14.
„ 4287 (1905). Marino. Secondary electric batteries. Feb. 7.
„ 5882 (1905). Candau and Candau. *See under* XIII*A*.
„ 6790 (1905). Potthoff. Apparatus for electro-plating tubes or other hollow articles. Feb. 7.
„ 9522 (1905). Bottomley and Paget. Electric resistance furnaces. Feb. 7.
„ 9657 (1905). Gouin. Accumulators. Feb. 7.
„ 11,040. (1905). Fuller. Electric batteries. Feb. 7.
„ 13,909 (1905). Lawson. *See under* XVIII*A*.
„ 20,217 (1905). Vareille. Apparatus for the electrolysis of water. Feb. 14.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 2877. Paul and Gillmann. Cleansing material. Feb. 6.
„ 3132. Pryor (Chem. Fabrik von Heyden, A.-G.). Manufacture of iodine fats.* Feb. 8.
[C.S.] 11,191 (1905). Braschler-Kurtz. *See under* III.
„ 10,387 (1905). Fresenius. Purification of fats, fat oils, resins and the like. Feb. 14.

Official Notices.

EXTRAORDINARY GENERAL MEETING OF THE SOCIETY.

Notice is hereby given that an Extraordinary General Meeting of the Society will be held at 3.30 o'clock, precisely, in the afternoon of Tuesday, the twenty-seventh day of March, 1906, at the House of the Society of Arts, John Street, Adelphi, W.C., by kind permission of the Council of that Society, with the object of considering and adopting the resolution mentioned in the Requisition hereinafter set forth:—

"To the President and Council of the Society of Chemical Industry."

We, the undersigned Members of the Society of Chemical Industry, hereby request that, in accordance with Bye-Law 40, you will convene an Extraordinary General Meeting of the Society with the object of considering, and if approved by the said Extraordinary Meeting, of adopting the following resolution (that is to say):—

Resolution.

"That it is desirable that the Society of Chemical Industry as now existing should be incorporated under and subject to the grant of a Royal Charter and that the Council be and hereby is authorised to take all necessary steps to procure the grant of a Royal Charter of Incorporation."

Dated this twenty-second day of December, 1905.

Here follow signatures of the following:—

George Beilby.
V. G. Bloede.
Jas. H. Bowman.
Eugene A. Byrnes.
Eustace Carey.
Prof. Frank Clowes.
Frederick P. Dewey.
Dr. Edward Divers.
Dr. A. R. L. Dohme.
Thos. Fairley.
Dr. Fred. W. Frerichs.
Oscar Guttmann.
Samuel Hall.
Jas. Otis Handy.
Dr. B. J. Harrington.
Dr. Edward Hart.
Otto Hehner.

Dr. H. W. Wiley.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906. All communications should be addressed to the General Secretary, Prof. Vittorio Villavecchia, Via Panisperna, 89, Rome.

The attention of Members is drawn to the Notice which accompanied the February 15th issue of the Journal.

The Executive of the Congress have arranged with Messrs. Thos. Cook & Son, of Ludgate Circus, E.C., 54, Piazza Esedra di Termini and 1B Piazza di Spagna, Rome, to procure suitable accommodation for members during the Congress, and a list of hotels has been prepared at which accommodation can be provided, with prices. Messrs. Thos. Cook & Son will also furnish, on application, full information as to train services.

The General Secretary will be obliged if those members who have made arrangements directly with the Congress Committee in Rome, will forward their names to the Society, in order that arrangements may be made for a headquarters in Rome and for combined travelling. It would also be of service if they would indicate their contemplated date of departure and proposed route, and also whether they have a preference for any particular hotel in Rome.

Deaths.

Bardsley, Robt., Messrs. Jewsbury and Brown, Manchester. Feb. 20.

Clark, Augustus, Fundicio do Bowman, Pernambuco, Brazil.

Hurst, G. H., 22, Blackfriars Street, Salford. Feb. 5.

Canadian Section.

Meeting held at Toronto on Thursday, October 19th, 1905.

DR. F. J. SMALE IN THE CHAIR.

A STUDY IN CRYSTALLISATION.

BY PROF. JAS. H. BOWMAN.

Those engaged in practical crystallisation are frequently confronted with the fact that many influences, some apparently trivial, affect the process. Great concentration or rapid cooling gives small crystals, less dense solutions or slow cooling produces larger ones. Agitation is also a factor to be reckoned with, as it diminishes the size, while quiescence furthers a large growth. Glauber's salt crystals, for instance, may be reduced to the size of those of Epsom salts, or increased to the dimensions of walnuts, according as these conditions are observed. Not only do we have the same substance crystallising in varying sizes, but in differing forms, so that in a large crystallisation it is sometimes difficult to find a typical shape. If this is true of chemically manufactured crystals, how much more does it apply to those produced in nature which engage the attention of the mineralogist? The crystals of the rocks are often distorted, twisted and compounded, in many cases being only partially formed and defective. The same mineral may vary in form as greatly as a cube differs from a fibre.

One is led to think that the force which causes matter to crystallise is either subject to many vagaries, or that the laws which govern it are frequently interfered with. These considerations suggest the desirability of a study of the force directing the tendency to crystallise.

It is common knowledge that the tendency to crystallise varies widely. The colloids do not crystallise; other substances assume the crystal form only under most favourable conditions and then, perhaps, but obscurely; and still others exist only in a crystalline state.

In studying the influences which affect crystallisation, it is necessary to keep this in mind, as it is assumed that the force with which we are dealing is the measure of this tendency to crystallise, so that in those substances which crystallise with difficulty interference would more readily take place than in those which are strong crystallisers.

If, with a fused crystalline substance, there be mixed a colloid, crystallisation will be interfered with. If, with a crystallised substance in solution, there be mixed a soluble colloid, interference with crystallisation will take place in a similar way. This interference will produce one or more of the following results:—

(a) Total prevention of crystallisation.
(b) Suppression of some of the lines of crystallising growth.
(c) Extension of the crystal to abnormal proportions, causing it to become a compound crystal.
(d) Blending, gyrating, and curving of the crystal or its

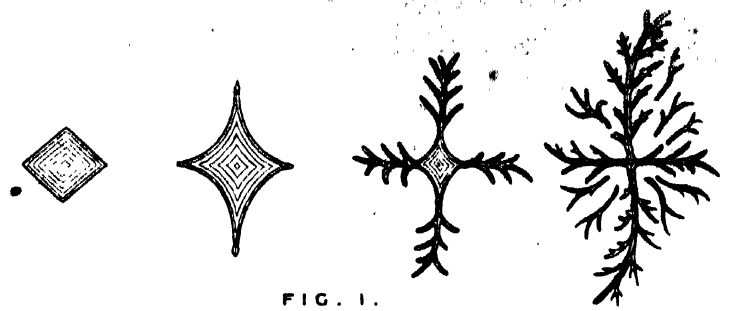

FIG. 1.

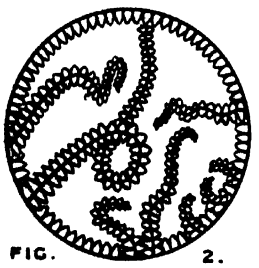

FIG. 2.

Santonine crystals in colloidal medium.

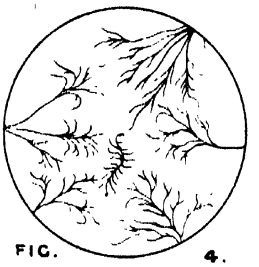

FIG. 4.

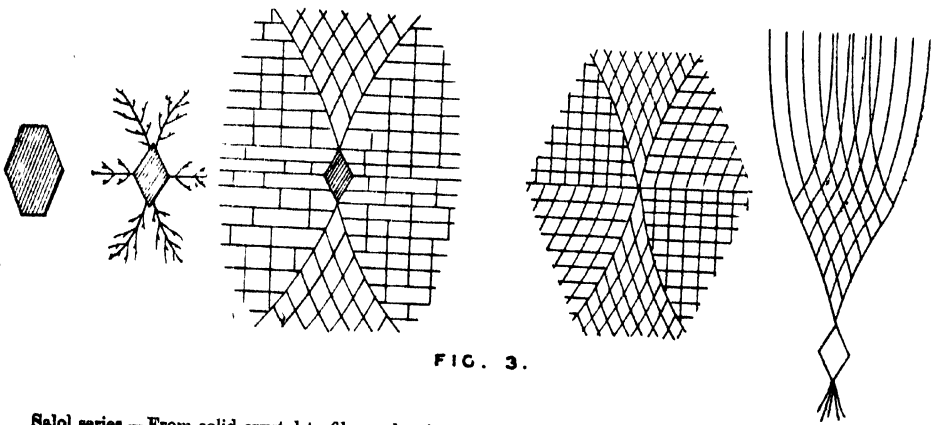
Grass-like crystals of potassium platinocyanide and gum arabic.



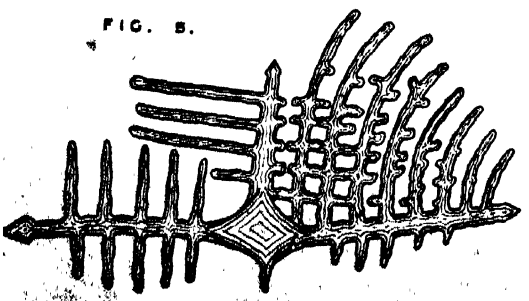


FIG. 3.

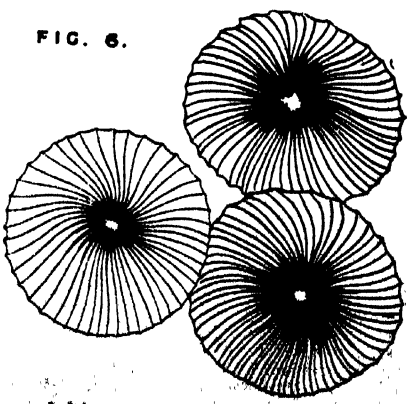


Salol series.—From solid crystal to fibres, showing reticulated "relay" crystals grown to many times their normal size, and relay taking place in both principal and subordinate lines of growth. Crystallized from fused salol and balsam.

FIG. 5.

Pyrogallic acid and castor oil showing "relay" on both principal and subordinate lines of growth.

FIG. 6.

A rounded form of crystal converted into radiating fibres, quite common in colloidal

In explanation of these results, I offer the following hypotheses:—

(1) That there are lines of force along which crystallisation takes place which differ in intensity according to the shape of the crystal and also to their nature whether principal or subordinate.

(2) That the interference with crystallisation referred to occurs because the supply of material is not available to the growing crystal as quickly as the crystallising force requires it.

Method of investigation.—I selected a number of crystallisable substances having the following characteristics:—

(1) They covered a large range, so far as crystallising tendencies were concerned.

(2) They had strong polarising action on light.

(3) They were readily dissolved or fused.

(4) They were miscible with some colloid and not too easily decomposed.

A small quantity of one of these substances was fused or dissolved on a glass slide, together with a suitable colloid, and allowed to crystallise by cooling or evaporation. This was repeated with varying proportions of the ingredients, thus forming a series.

The first clause of the hypothesis, *viz.*, that there are directing forces in a crystal and that they manifest themselves in lines, of which there are principal ones leading from the centre of growth, and subordinates lateral to them, may be readily shown by crystallising a solution of common salt in gum arabic water, on a glass slide. (See Fig. 1, which is a fair sample of the result which may be obtained from a large number of substances treated in this way.)

The second clause, *viz.*, that crystallisation is interfered with by lack of supply, was demonstrated in these experiments by introducing a colloid with the solvent or fused substances. Fig. 2 is a slide of santonine. The medium with which the santonine was mixed in this case was a colloid, which is solid at ordinary temperatures and is soft, but not liquid, at 100° C., at which temperature the substance was allowed to crystallise. The determined efforts of the santonine to crystallise are here well illustrated in its gyrations and loopings. By increasing the proportion of colloid, crystallisation was completely prevented.

The following principles are operative, under the conditions of the experiments, in the formations of the crystals:—

(1) Initiation; (2) Repression; (3) Relay; (4) Curving.

Initiation.—It is a familiar fact that if a crystal be introduced into a solution of the same substance, crystallisation will be induced. As an illustration, I may instance fused salol, which, when touched with a small salol crystal adhering to a needle point, immediately begins to crystallise. This "initiation" is a very important principle in all stages of the process of crystallisation.

Repression.—When crystallisation is taking place in a liquid, currents are set up, to and from the forming crystals. The rate of the currents is affected by the strength of the crystallising force and, also, by the thickness or viscosity of the liquid. If the supply of material is not brought to the crystal as fast as the crystallising force demands, the growth will follow the principal lines, *i.e.*, the lines of strongest force, and result in the suppression or partial suppression of the subordinate lateral lines, this giving the crystal a tendency to become fibrous or filiform.

Relay.—By this I designate a process by which a compound crystal is formed. It may be described as follows:—The growing point of a crystal pushes itself into new material and becomes the cause of initiation. The advancing crystal is repeatedly relayed by the force of other crystals, and in this way will grow indefinitely, unless prevented, either by obstruction or lack of supply. Not only does relay take place along the principal force lines, but along the subordinate ones as well. When the latter are "relayed" they initiate lines equal, or nearly equal, to the principal ones. (See Figs. 3 and 5.)

Curving.—Where the crystallising force is nearly equalled by the resistance of the medium due to its viscosity, the crystal seeks the line of least resistance, which seems to be a gyratory one. The result is the twisting and curving of the crystal or its parts into feathery, fern-like or arborescent shapes.

Between the normal crystal and the fibre many stages exhibit themselves, as shown in the illustrations, *viz.*, reticulated, grass-like, fern-like, arborescent, &c. See Figs. 3, 4, 5 and 6. To exhibit these forms there were projected on the screen slides of tartaric acid, antipyrin, potassium quadroxalate, salicylic acid, oxalic acid, pyrogallol, &c. Illustrations of these forms may also be found among minerals, in zinc, on the surface of galvanised iron sheets, and more familiarly still in the frost-work on our windows in winter. The logical inference from these experiments is that all crystals, if treated by some suitable method, may be made to elongate or twist or even become fibrous. I have found this result in so many cases that I think it may prove true of all, save where the crystallising force is so strong that no colloid, equal to the task of restraining it, can be found.

In crystals having one diameter longer than the other, the conversion to the fibrous form is easier than where the diameters are alike. In studying the building of a crystal, the growing edge should be the point of observation. The foregoing demonstrations make this very apparent.

A crystallisation which admirably illustrates my position, and at the same time gives extremely beautiful effects with the projection apparatus, is that of camphor monobromide. The crystal is formed by fusing a small quantity of the salt with some fir balsam on a glass slide, placing over the mixture a cover glass and allowing it to crystallise. It forms a mass of curving, feathery, concentric rainbows of brilliant colours, and, as an exhibition of crystal growth, can hardly be excelled. Heated to about 70° C. it will fuse, and if then placed in the lantern or on the microscope stage, in a few seconds it will begin to crystallise and for some time will give very beautiful and instructive results. By varying the proportion of the salt and the balsam, the principles I have been contending for, may be illustrated. A mica plate improves the exhibit.

Liverpool Section.

Meeting held at Liverpool, on Wednesday, 10th January, 1906.

MR. EUSTACE CAREY IN THE CHAIR.

HURTER MEMORIAL LECTURE.

THE UNION OF CHLORINE AND HYDROGEN.

BY HAROLD B. DIXON, M.A., F.R.S., late Fellow of Balliol College, Oxford; Professor of Chemistry in the University of Manchester.

That one, who has devoted a large part of his scientific life to the study of the influence exerted by minute traces of matter on chemical reactions, should be invited to give the Hurter Memorial Lecture is, I take it, not only a compliment to me, but a tribute to the catholicity of the man in whose honour we meet here to-night. Those who knew Ferdinand Hurter admired him not only as a man of indomitable energy and remarkable insight, and of wide reputation in the domain of applied chemistry, but also as a man whose soul, soaring above mere results, ever desired to penetrate the mysterious mechanism of chemical change. I make no apology then in asking you to consider, in this lecture dedicated to Hurter's memory, the mode of combination of chlorine with hydrogen, and the extraordinary influence exerted by traces of foreign matter on the reaction, a study interwoven with that so ably worked out by Hurter on the decomposition of hydrochloric acid by oxygen.

My own work on chlorine was begun with the object of

testing the law of mass action in gases. I had studied the division of oxygen between hydrogen and carbonic oxide (the original problem attacked by Bunsen), and had found it complicated by the fact that oxygen and carbonic oxide are largely inert towards one another in an explosion. A simpler case seemed to be presented by the division of hydrogen between oxygen and chlorine. In conjunction with my pupil Mr. J. A. Harker, I measured the small contraction which took place when electrolytic hydrogen and chlorine combined in a glass vessel, and found it to be due to the condensation of hydrogen chloride on the surface. Mr. Harker carried out the experiments on the explosion of the three gases, and found that an equilibrium was reached between two opposite chemical changes:

$$4HCl + O_2 \rightleftarrows 2H_2O + 2Cl_2$$

similar to that found for hydrogen, carbonic oxide and oxygen:—

$$H_2O + CO \rightleftarrows H_2 + CO_2.$$

In the next place we were driven to measure the velocity of explosion of electrolytic hydrogen and chlorine. Among the many possible reactions of gases, I think no one would choose those of chlorine as a subject for exact quantitative study, if he could find any other gas that would answer his purpose. In my case, I could find no other gas having the desired properties, *viz.*, that it should explode with another elementary gas, that the product should be nearly a perfect gas, and that no alteration of chemical volume should accompany the change. A mixture such as hydrogen with nitrous oxide gives water-vapour on explosion; a mixture of cyanogen with oxygen in equal volumes gives a product of sufficiently perfect gases (carbonic oxide and nitrogen), but there is an increase from two volumes to three. Now I had been led to develop a theory of the explosion-wave in gases which attributes the propagation of the explosion to the movement of an intense sound-wave through the gases, a wave which is re-inforced and kept uniform from layer to layer by the chemical action accompanying the collisions of the molecules in the wave-front. The theory did not fit with the facts observed when carbon compounds were burnt to carbonic acid, or when hydrogen compounds were burnt to water-vapour at the highest temperatures of the explosion. The explanation appeared* to be the dissociation of the carbon dioxide or water formed in the wave-front, for, on diluting ordinary electrolytic gas with excess of hydrogen or oxygen or nitrogen, the found rates approximated more and more to the rates calculated by the theory. On the other hand, when the chemical volume was altered by the change, the products would be, for the moment, hotter or colder according as the volume was increased or diminished—just as if they had been suddenly compressed or rarified mechanically. In calculating the theoretical rate of the "sound-wave" in the explosion of such gases, I assumed the temperature must be raised or lowered by the adiabatic compression or rarefaction corresponding to the change in volume. But obviously such an assumption required to be confirmed by experiments with mixtures which did not alter in volume. What mixture would give the same volume on explosion, and also a nearly perfect gas as product of the explosion? The *only* mixture I could think of was that of chlorine with hydrogen, exploding to hydrochloric acid. Accordingly this mixture had to be tried.

The first difficulty was to obtain a tube sufficiently long to measure the explosion-wave in; for the theory indicated that it would travel about 1700 m. per second. A platinum tube 50 m. long, and about 10 mm. in diameter would have answered the purpose. In default of this I tried various baser metals, hoping that a coating of chloride once formed might protect the tube from further action. But the tubes had voracious appetites which could not be allayed; the chlorine seemed, like Cleopatra, to make them hungry when most she satisfied. Then I turned to glass. I thought that a long tube might be drawn out and coiled as it was drawn, but my request to manufacturers to make me such a coil met with expressions of derision which left me a little sore. At length I received an invitation from a firm in Manchester to visit their works, where I had the pleasure of seeing such liberties taken with hot glass that I had great hopes they could easily draw me a tube say—to be modest—60 ft. long. But when I put my hopes into words I was met by the crushing rejoinder:—"You have seen our works; *where* do you think we have got room to draw a tube 60 ft. long? The thing is impossible!" I retired crest-fallen; but the firm were better than their words. A month afterwards I received a note from them saying "we have drawn you two straight tubes 34 and 31 ft. long, come and take them away." I had not thought about the tubes being *straight*, and for a moment their transport presented some difficulty. But very early one morning four men might have been seen marching through Manchester with a long ladder on their shoulders. The tubes were loosely tied to the ladder, and by the removal of a window frame, the ladder was introduced into a corridor of the laboratory, where the two tubes were joined together and my dream of a 60 ft. glass tube became in reality one of 65 ft. The apparatus was completed by attaching a short metal tube at either end to carry the silver-bridges, taps, firing wires, &c.—the interior of these tubes being coated with paraffin and filled with hydrogen and oxygen. They were joined on to the glass tube (when the latter was filled with hydrogen and chlorine) immediately before the gases were fired. A year later it was possible to obtain 6 ft. iron tubes lined with glass, tubes which could be screwed up tight to one another with paraffined asbestos washers. In this way I built up a glass tube 120 ft. long, and confirmed the earlier experiments.

The first point to determine in the explosion of hydrogen with chlorine, was whether aqueous vapour retarded or facilitated the explosion. I knew of no published researches on this point, when our measurements began; most experimenters had used moist gases. But Pringsheim's work (1887) showed that moisture has a great effect on the union of hydrogen with chlorine under the influence of light, and our work confirmed this in a striking way. We found the light required to explode hydrogen and chlorine, when dried by phosphorus pentoxide, was 25 times more intense than that required to explode the moist gases.* I can easily demonstrate to you the effect of drying the gases, by submitting a dry and a wet bulb to the light from a "magnesium flash" equidistant from the two bulbs. The wet bulb is shattered to powder, the dry bulb remains intact. But this is not the case when the gases are fired by an electric spark. The mean velocity of the explosion-wave in dried hydrogen and chlorine is 25 m. per second *faster* than the mean velocity in the moist gases. In other words, once the explosion-wave is set up by the spark, it appears to travel independently of the moisture present which merely acts as a diluent. The velocity of explosion in electrolytic chlorine and hydrogen was found to be rather less than the velocity calculated by my sound-wave formula, but much nearer to the calculated number than in the case of the explosion of electrolytic oxygen and hydrogen. When a mixture of two volumes of hydrogen with one of chlorine was exploded, the found and calculated velocities were in close agreement. I interpret this to mean that, in the explosion of equal volumes of hydrogen and chlorine, the temperature in the wave-front is high enough to dissociate some hydrogen chloride. In the following table I compare the found and calculated rates of explosion for some very different mixtures of gases:—

Rates of the explosion-wave in metres per second.

Mixture.	Found.	Calculated.
$8H_2 + O_2$	3,535	3,554
$H_2 + 3O_2$	1,712	1,740
$2H_2 + Cl_2$	1,849	1,832
$C_2N_2 + O_2$	2,728	2,725
$C_2H_2 + 2O_2 + 8N_2$	1,734	1,727

It is almost inconceivable that the rates of explosion for such very different mixtures of gases could be given

* These experiments have been repeated with great care by H. B. Baker and by Mellor and Russell with chlorine and hydrogen prepared in different ways. The thoroughly dried gases not only resist the action of sunlight, but require a much higher temperature to start their combination.

by the formula unless the mode of propagation were similar in each case. I believe, therefore, that chlorine combines directly with hydrogen at the high temperature of the explosion wave.

The first observation on the union of hydrogen and chlorine under the influence of light is due to W. Cruickshank in 1801. Dalton, in the summer of 1809, experimenting with the mixed gases over water, noticed that a diminution did not take place immediately on exposure to light, but only after a minute or two; that the more powerful the light the more rapid is the combination; that the combination is checked by shading the eudiometer; and that bright sunlight causes an explosion. Gay-Lussac independently observed the explosion of the mixed gases in bright light.

The systematic study of the action of light on hydrogen and chlorine was taken up by Draper in 1843. He devised an ingenious U tube for preparing the gases electrolytically, and storing them over water saturated with chlorine in the closed arm of the U. The diminution in volume, owing to the formation of hydrogen chloride and its solution in the water, was read off on a scale attached to the open arm. This instrument he called a tithonometer, and the action of light on the mixture he called tithonisation. The name is a somewhat puzzling one. The only derivation I can think of is from the Greek demi-god Tithonos, the husband of Aurora. Now Tithonos is pictured in Greek mythology as a decrepit old man shrinking before the brilliance of his wife—the goddess of the dawn. Tithonisation would, therefore, be the process by which a man absorbs the penetrating shafts directed upon him by his more brilliant wife, and finally shrinks up when she casts the light of her countenance too continuously upon him. The name may be appropriate for the absorption of light and the subsequent shrinking of hydrogen and chlorine—though we cannot help wondering whether Dr. Draper was a confirmed misogynist. Sir Henry Roscoe, with greater gallantry, has rejected the name in favour of "actinometer."

Armed with his tithonometer Draper proved that a large amount of radiant matter is absorbed before chemical combination takes place, that combination then begins slowly and increases in rapidity until a constant rate is attained. He showed that the change impressed on the chlorine by the absorption of light prior to the combination was not lost on standing in the dark for some hours. Draper also showed that the maximum sensitiveness to light was attained when the gases were present in exactly equal volumes, a small excess of either gas retarding the rate of combination considerably.

Draper established the fact that after the rate of combination had become constant the movement of the tithonometer was proportional to the quantity of the incident rays.

One of the most important observations made by Draper is that chlorine, when exposed to sunlight, and then mixed (in the dark) with hydrogen, combines *immediately* with the hydrogen when the mixture is exposed to diffused daylight; whereas "non-insolated" chlorine, when mixed with hydrogen in exactly the same way, shows a long period of inactivity. This change in the chlorine produced by sunlight lasts a long time, and is not due to any temporary elevation of temperature. Draper, therefore, regarded the light as being absorbed by the chlorine and as exalting its affinity for hydrogen: insolated chlorine being thus an allotropic form of ordinary chlorine. It has always appeared to me difficult to explain away the fact recorded by Draper; but other observers, working with apparently more delicate instruments, failed to detect any difference between insolated and non-insolated chlorine. It remained for Bevan to explain this discrepancy.

Bunsen and Roscoe greatly improved the apparatus for observing the action of light on the mixed gases, and their actinometer has served as the model for all subsequent instruments used in these investigations. It will be interesting, therefore, for you to examine the actinometer on the table, one of the original instruments devised by Bunsen and Roscoe. I think the chief improvement we have since made in this apparatus is in the electrolytic cell, where we use for the electrodes carbon rods *fused* into glass tubes. Working with this actinometer, Bunsen and Roscoe proved conclusively that pure electrolytic chlorine and hydrogen, in equal volumes, when exposed to light, form no hydrochloric acid for the first few moments, but after a time they begin to combine with a gradually-increasing rapidity until a permanent constant action is attained. This "period of induction," as Bunsen and Roscoe called it, was attributed by them to the breaking down by the action of light of a resistance to the combination of the two gases; they did not consider that the chlorine was altered *per se* by the light, or its affinity exalted. In fact, their experiment of bringing the insolated gases by separate tubes into the induction vessel appeared to show that chlorine, when illuminated by itself, was just in the same condition as unilluminated chlorine. This discrepancy, Bevan has shown, is due to the action of the water in the induction vessel. If chlorine is illuminated over water (as in Draper's experiment) and hydrogen is added to it, the mixture is found to be sensitive to light; if the chlorine is illuminated in a tube and then bubbled through water, the "activity" of the chlorine may be destroyed by the water (as in Bunsen and Roscoe's experiment). It still remains to be explained why the water should so act, and on this problem I hope to show you some very recent experiments that throw light on it.

On another important feature of the "Induction" Bunsen and Roscoe's experiments differ from those of Draper. Draper thought that the induced gases retained their sensitiveness indefinitely; Bunsen and Roscoe found that the induction effect gradually died away in the dark, although the diminution of activity in the dark was much slower than the increase in the light. Here, again, an explanation of this gradual diminution of sensitiveness has only recently been attained. Bunsen and Roscoe also showed the great effect on the amount of combination due to the presence of a small excess of either of the gases, hydrogen or chlorine; and the still more marked diminution caused by the presence of small amounts of oxygen. This marked effect of small quantities of the reacting gases shows that the combination in the light is not governed by the ordinary law of mass action.

When the chlorine and hydrogen mixture brought to the sensitive state is illuminated for an instant, *e.g.*, by an electric spark from a Leyden jar, there is a sudden expansion of the gases, followed immediately by a contraction. This effect was described by Draper. Pringsheim, who seems to have rediscovered this "Draper effect" independently, attributes it to the dissociation of the molecules and the recombination of the dissociated atoms. He considered that he had shown that no hydrochloric acid was produced by the momentary illumination, and, therefore, that the expansion could not be a heat effect. Pringsheim was the first to produce evidence that water took part in the reaction between chlorine and hydrogen under the influence of light. His idea was that the steam was decomposed by the chlorine forming an intermediate compound, *e.g.*, an oxide of chlorine, which, in turn, was decomposed by the hydrogen with formation of hydrochloric acid and water:—

i. $H_2O + Cl_2 = H_2 + Cl_2O$.
ii. $Cl_2O + 2H_2 = 2HCl + H_2O$.

The rate of production of hydrochloric acid depends, then, on the amount of hypochlorous oxide present, and this depends on the length of exposure and the intensity of the light. When the rates of formation and decomposition of the hypochlorous oxide have become equal, the formation of hydrochloric acid will continue at a constant rate which will depend upon the intensity of the light.

Among those who have worked in the Owens College during recent years on the union of hydrogen and chlorine Dr. J. W. Mellor has particularly studied the "Draper effect." He has shown, I think conclusively, that the sudden expansion is always accompanied by the formation of hydrochloric acid, and is probably due to the heat evolved in its formation. Mellor has proved that if an intermediate body is formed in the period of induction, it cannot be either hypochlorous oxide or the corresponding acid, hypochlorous acid, for the addition of either of these bodies does not hasten the combination. To account for the period of induction

Mellor assumes that an intermediate "associated" compound is formed by the chlorine, water and hydrogen. Bevan, on the other hand, having shown that moist chlorine is made active by light, as Draper had stated, assumes that an intermediate compound of chlorine and water is first formed, and that this reacts with hydrogen forming hydrochloric acid and water.

Another mode of attacking the problem of the mode of action of light is to determine the filtering effect of chlorine on the actinic rays. Bunsen and Roscoe found that a mixture of chlorine and hydrogen absorbed more light than a mixture of chlorine with an inert gas; and Mellor has found that moist chlorine forms a better light-screen than dry chlorine. Further experiments on these lines are wanted.

I have now to bring before you a short account of the recent work which has been carried out in the Owens College by Messrs. D. L. Chapman and C. H. Burgess. The details of their experiments and their theoretical conclusions are not yet published, but I am permitted to show you experimentally with one of their actinometers the important fact they have established, *viz.*, that mixtures of hydrogen and chlorine may be made which retain their sensitiveness to light for an indefinite period—mixtures that have in short no period of induction. According to Chapman and Burgess the pure gases always combine instantaneously; it is the presence of impurities in minute traces that produces the period of induction.

In their earlier experiments, Chapman and Burgess proved that the gaseous mixture, rendered active by light, lost its activity on standing over water in the dark, but that this loss became less marked on each repetition of the experiment with the same water. Finally, however, the loss, though slight, *did not entirely disappear*. This led them to suspect that the induction period might be due to some impurity, and that the water might acquire from the glass vessels something that retarded the rate of combination. These experiments clearly established the necessity of making the water "active" as well as the gases themselves. When salt solutions, *e.g.*, calcium or barium chloride were employed instead of water, far longer induction periods were observed. But after sufficient insolation and shaking of the solution with the gases the latter became as sensitive as over water. The substitution of a quartz vessel for the glass actinometer appeared to confirm the view that glass destroyed the activity; but the effect was really due to the fact that the quartz vessel had been heated in order to drive out the air. Experiments at 100° C. soon demonstrated that water and salt solutions heated with chlorine became rapidly "active." The question whether the decay of activity on standing in the dark was increased by raising the temperature was also tested; the rate of decay of thoroughly insolated gas over barium chloride solution was *diminished* by heating. If light produces some "active principle" in chlorine capable of bringing about the combination of hydrogen and chlorine, heat also has the power of producing the same principle in chlorine water, and water saturated with this "activity" no longer dissolves out the active principle from the active gases in contact with it. Moreover, the "activity" cannot be pumped out of the solution with the dissolved chlorine; on the contrary, a solution from which the chlorine had been pumped away was found to be more "active" than the solution saturated with chlorine.

Chapman and Burgess had now shown that solutions of certain salts had the power of stopping the formation of hydrochloric acid for many hours, but that once the induction period was over the gases combined rapidly under the action of light. This was difficult to reconcile with any theory of the gradual formation of an intermediate compound, since such a compound should be formed at the same rate that it is afterwards decomposed when the constant state is reached. Again, Chapman and Burgess introduced into an active mixture of hydrogen and chlorine, standing over an active solution, an equal volume of an uninsolated mixture of the gases. If an intermediate compound were already present in the active gas, one would expect that its effect would be diminished by the dilution, but the formation of hydrochloric acid was absolutely stopped for a considerable period.

The difficulty of reconciling these several results with any theory of the formation of an intermediate compound led Chapman and Burgess to consider another possible explanation. Could the solution contain some impurity which alone or by reacting with chlorine could give off a volatile body capable of stopping the reaction until completely destroyed? Ammonia seemed such a possible impurity, and experiments promptly showed that it possessed the required properties. Solutions rendered "active" by boiling with chlorine were rendered "inactive" by the addition of a trace of ammonia when cold. On exhaustion, the ammonia or its chlorine derivative was removed, and, of course, on boiling the solution with chlorine the ammonia was destroyed. Chapman and Burgess have shown that the induction period is proportional to the quantity of ammonia in the water. They have further shown that the very slow decay of activity, found when the active actinometer is allowed to stand for several days in the dark, is due to the oxidation of some trace of albuminous substance in the water with the formation of ammonia or its derivatives. Water or salt solutions which have been well boiled with chlorine show no "decay."

The actinometer on the table before you was prepared by Mr. Chapman and has now been standing some 28 hours in the dark. I will ask you to observe the position of the index on the scale while I flash on to the bulb the rays from an incandescent electric light. Notice the instantaneous expansion (the Draper effect) followed by the steady movement of the liquid along the scale towards the bulb. There is no period of induction but a uniform formation of hydrochloric acid.*

But if Chapman and Burgess have explained the induction period by their laborious research and close reasoning, we have still to answer the question "How does the water-vapour influence the combination?" If chlorine can act on hydrogen in presence of water, why does it not do so so long as the ammonia-impurity is present? It is conceivable that chlorine slowly forms a compound with water, and that this compound rapidly acts on the ammonia-impurity by chlorination, hydrochloric acid being formed only when all the impurity is destroyed. But to my mind there are great difficulties in this view. The facts established by Chapman and Burgess can, however, be otherwise interpreted. I have not seen their interpretation, but, on thinking over their experiments, several possible solutions presented themselves to me, and one interpretation which I think worthy of your notice was suggested to me by the phenomena—so much under observation at this moment—of a large political meeting. The individuals—the molecules of the meeting—were not reacting under the stress of collisions in a more or less heated state; they—like our hydrogen and chlorine molecules in light—were being acted on from a distant platform by mere vibrations of a sympathetic kind, and were being induced and stirred to future action. Suddenly a young lady waved a banner and lifted up her voice—unsympathetically. If it had been a question of a change brought about by *collisions* between individual *bodies*, the young lady would have had very little chance to effect anything among so many more powerful bodies; but her effect on the *harmony* of the meeting was instantaneous and complete. The whole programme of proceedings was stopped for half an hour.

Suppose that the system Cl_2, H_2O, H_2 is set gradually vibrating by light and that, when the proper harmonic vibration is set up, then it is possible for chemical change to occur. Now the presence of a small quantity of a vibrating body "out of tune" might stop the harmonic vibration of the other molecules, and so stop the chemical action. A very small proportion of the discordant body might suffice.

I told Mr. Chapman my interpretation of his facts when he at once said, "That is the essence of the explanation I have worked out."

---

* On repeating the experiment after the lecture, a drop or two of the liquid from the scale tube entered the bulb. On drawing the liquid back and re-illuminating the bulb, there was a distinct period of induction lasting 2 or 3 minutes. The trace of impurity in the index liquid was then destroyed, and further experiments showed no induction.

I have in conclusion to invite your inspection of the apparatus which Mr. E. C. Edgar and I have recently used to redetermine the atomic weight of chlorine by combining it directly with hydrogen. When we commenced this work, four years ago, it required some courage to think that any useful purpose could be served by redetermining a constant which the highest living critic declared had been measured with "the magnificent accuracy of Stas' determination." But, by the time our measurements were completed, evidence began to come in indirectly that possibly even Stas might have made a mistake. But apart from any considerable error in any of Stas' determinations, the very indirect method by which the atomic weight of chlorine had been determined made it certain that an error in any part of the chain connecting chlorine with hydrogen would be repeated from link to link, and would become evident only when the two ends of the chain were connected up.

A direct comparison between hydrogen and chlorine might not only serve to detect any systematic error in this chain of ratios, but such a comparison, inasmuch as it does not involve the probable errors of other ratios, would be *cæteris paribus* more exact. Again, the closing of the chain between hydrogen and chlorine with reasonable accuracy would permit the accidental errors to be distributed and prevent their accumulation at the unconnected end. The accumulated probable error in Clarke's recalculated value for chlorine is 0·0048; the probable error of the mean of our nine experiments is 0·0019.

The suggestion to carry out this work was made to us by Professor Edward W. Morley, who happened to visit our laboratories when pure chlorine was being prepared by the electrolysis of fused silver chloride. He suggested that we should burn weighed hydrogen and chlorine in a closed vessel, just as he had burnt weighed hydrogen and oxygen.

Chlorine was prepared for our determination by the electrolysis of silver chloride fused in a Jena glass U-tube, to the arms of which purified carbon poles were *fused*. The chlorine was condensed to a liquid and weighed in a glass bulb connected with a sealed tube and tap. After the bulb had been weighed and brought into position, the sealed tube was broken by a small glass rod falling on it inside the apparatus. The gas could then escape by the tap and ground tubulure into a large combustion-globe. The tap had the peculiarity that its smaller diameter was at the top, so that instead of the key having to be *pushed* into its sheath, it had to be *pulled* into it to fit. The pressure of the chlorine, therefore, instead of tending to loosen the key, only made it fit more tightly. The hydrogen, prepared by the electrolysis of a hot solution of barium hydroxide, was dried by potash, passed over heated spongy platinum to eliminate any oxygen, then through long U-tubes filled with purified phosphorus pentoxide, and was finally absorbed by palladium. After the apparatus had been well washed out with hydrogen, the palladium bulb was sealed off and weighed. The hydrogen was introduced slowly from the palladium into the combustion-globe previously filled with chlorine. A spark lighted the jet which was kept burning by regulating the supply of the two gases until all the chlorine had been volatilised. About 2 per cent. of chlorine remained unburnt in the globe, which contained pure water to absorb the hydrogen chloride as it was formed. The residual gases were then analysed.

The mean of our nine determinations gives the atomic weight of chlorine as 35·195 if H = 1, or 35·463 if O = 16. Our value is considerably higher than that given in Prof. F. W. Clarke's "Recalculation of the Atomic Weights," *viz.*, 35·447. But that Stas' figure is too low has been confirmed indirectly by the work of Prof. Theodore Richards on the ratio between silver and chlorine, and by the work of Dr. Scott and of Mr. R. W. Gray on the atomic weight of nitrogen. It may indeed turn out that the highest of the values found in our nine experiments are more nearly correct than the mean. Mr. Edgar is continuing the investigation and hopes to avoid one source of error by burning the chlorine at a jet in an atmosphere of hydrogen.

We have to thank our glass-blower, Mr. Otto Baumbach, for the skill with which he has made this apparatus.

London Section.

Meeting held at Burlington House on Monday, February 5th, 1906.

MR. R. J. FRISWELL IN THE CHAIR.

THE LOSS OF NITRE IN THE CHAMBER PROCESS.

PART II.

BY J. K. H. INGLIS.

(See also this J., 1904, 643.)

Up till the last few years the methods which have been available for the analysis of a mixture of gases have been those in which the changes in volume of the gases have been measured either when the gases were passed through some liquid which absorbed one of the constituents, or when chemical action between two or more of the constituents was brought about by means of a spark. Now although these methods are quite satisfactory when the percentages of the different constituents are all tolerably large, they are not at all accurate or convenient when the constituents which are to be estimated form only a very small percentage of the whole. Thus, for example if the percentage of carbon dioxide in the air is to be determined by measuring the contraction that takes place when a given volume of the air is treated with potash, an extremely elaborate and complicated apparatus is necessary in order that the changes in temperature and pressure may be compensated. Hence such a determination is more conveniently carried out by determining the carbon dioxide itself by chemical methods, *e.g.*, by absorbing it in standard baryta and titrating the excess of baryta with oxalic acid. But in a case in which the constituent cannot be absorbed in such a way (*e.g.*, nitrous oxide), the analytical methods have almost completely failed.

The discovery of convenient methods for preparing liquid air at a moderate cost has placed a new method in the hands of the analyst. For many years the chemist has been in the habit of separating liquids from one another by the process of fractional distillation; and since by means of liquid air nearly all gases can be turned into liquids or solids, one has only to devise methods for the convenient fractionation of these solids and liquids in order to produce the desired separation. In the case of the ordinary distillation of liquids the process is usually carried out at constant pressure and the separation of two miscible liquids can be carried out completely only if the line representing the dependence of the boiling point upon the composition of the liquid presents no minimum or maximum. In the case of the distillation of liquefied gases, however, it is more convenient to carry out the distillation isothermally; and although the above limitation still remains valid, yet the conditions of temperature and pressure can be changed so readily that the separation is more likely to be complete.

The methods for the fractionation of liquefied gases were first worked out and used by Ramsay and Travers (Proc. Roy. Soc., 1898, **63**, 438; **64**, 183; Phil. Trans. 1901) in their work on the new gases of the atmosphere, and the fact that krypton and xenon were discovered although they amount to only one part in several millions by volume, shows what an extremely good separation can be effected by this method. It seemed possible that the same process might be suitable for the solution of some of the difficult problems in gas analysis; and Sir William Ramsay kindly suggested that I should attempt to solve in this way a problem which arises in connection with the chamber process for the manufacture of sulphuric acid. In this manufacture an amount of nitre has to be continually supplied which is equal in weight to about 5 per cent. of the total sulphur burnt. A large number of investigators have attempted at different times to discover what becomes of this nitre, but their efforts have not been very successful. The result has been that manufacturers have not known to what this loss was due, and therefore have not been able to prevent it.

Now, whatever view we take of the theory of the reactions in the chambers, the nitre must be considered as being present either as nitric oxide, nitrogen trioxide, or nitrogen peroxide, and if there is sufficient excess of oxygen the nitre should not be present as nitric oxide for any length of time. Hence, since nitrogen trioxide and peroxide are both soluble in sulphuric acid (C.O.V.) forming nitrosulphonic acid NO_2SO_3H (and possibly nitric acid) they should be retained by the acid which passes down the Gay-Lussac tower. This acid, when it is passed down the Glover tower, is denitrated by the sulphur dioxide coming from the burners, and the reaction may be written as

$$2NO_2SO_3H + SO_2 + 2H_2O = 3H_2SO_4 + 2NO.$$

Hence, since the nitric oxide formed passes on into the chambers, all the nitre should be retained in the plant and theoretically no fresh supply should be needed. When it was found that, in spite of the Gay-Lussac towers, a steady supply of nitre was necessary, two rival theories arose to explain the loss. According to the one theory (Vorster, "Dingler's Journal," **213**, 506), which was brought forward as an objection to the use of the Glover tower, there took place in this tower, in addition to the action already given, the following reaction:—

$$2NO + SO_2 + H_2O = H_2SO_4 + N_2O.$$

In this way a portion of the nitrous gases was supposed to be reduced to nitrous oxide, and as this is not absorbed by the sulphuric acid in the Gay-Lussac tower, and, in addition, is of no use in the manufacture of sulphuric acid, it would be a total loss. Lunge ("Dingler's Journal," **225**, 474) showed, however, that the conditions under which Vorster carried out his experiments never obtained in the Glover tower, and maintained that the loss due to the formation of nitrous oxide could never be very great. The other theory was that the loss took place solely because of incomplete absorption in the Gay-Lussac tower. This incomplete absorption might be due (1) to the nitre remaining as nitric oxide, and therefore being unabsorbed, (2) to insufficient contact between the gases and the sulphuric acid, or (3) to the fact that the nitrous vitriol formed would have a certain dissociation pressure, and that therefore a certain proportion of the nitrous gases would always remain unabsorbed. But since, in the Gay-Lussac tower, the gases come in contact with a stream of sulphuric acid flowing the opposite way, they should, as they leave the tower, be in equilibrium with the acid entering the tower, *viz.*, pure sulphuric acid, and therefore should contain no nitrous gases. For many years a controversy raged between the exponents of the "chemical" loss and those of the "mechanical" loss, and the question has never been satisfactorily settled. There is no doubt that the chemical loss was at first greatly exaggerated, some chemists (this J., 1884, **3**, 134; 1889, **8**, 167) even saying that the chemical loss could account for 31 per cent. of the nitre lost. But in the same way, Sorel ("Traité," pages 313, 393) declared that the unavoidable mechanical loss amounted to 95 per cent. of the whole loss. In all probability the loss was due to both causes.

Since, according to both theories, the nitre was carried away in the flue leading from the Gay-Lussac tower, it might be thought that an analysis of these flue gases would prove which theory was the correct one. But in these flue gases there was a very large proportion of nitrogen and oxygen, and therefore analyses were difficult to carry out. Some nitrogen peroxide and some nitric oxide were certainly present, but it was difficult to absorb them completely. In addition to this, the flue gas usually contained a small quantity of sulphur dioxide, and when the gases were passed through any absorbent a complicated series of side reactions took place between the nitrogen peroxide and the sulphur dioxide, and the result was that the analytical data could not be interpreted. In addition to this, there was no absorbent for nitrous oxide when its partial pressure was so small, and, therefore, its presence could not be detected much less estimated. This problem, therefore, seemed to be one which might be solved by carrying out analyses by means of fractionation at low temperatures.

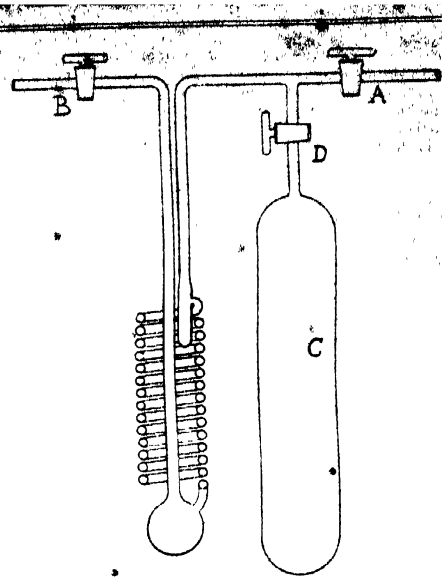
Since the nitre lost (calculated as sodium nitrate) is equal in weight to about 3 per cent. of the sulphur burnt, it is possible, if we assume that the whole nitre lost is carried away in the flue gases, to calculate what proportion by volume this loss represents. In the pyrites burners about 48 per cent. of the ore is sulphur which burns to form sulphur dioxide, another 48 per cent. is iron, which burns to form ferric oxide, and the remaining 4 per cent. remains more or less unchanged. Now, 32 grms. of sulphur will require $\frac{3}{2} \times 22{\cdot}4$ litres of oxygen to form sulphur trioxide, and 56 grms. of iron require $\frac{3}{4} \times 22{\cdot}4$ litres to form ferric oxide. Hence 100 grms. of ore require $\left(\frac{48}{32} \times \frac{3}{2} + \frac{48}{56} \times \frac{3}{4}\right) \times 22{\cdot}4$ litres of oxygen $= 64{\cdot}8$ litres. The flue gases usually contain about 6·5 per cent. of oxygen, which is 5·5 per cent. of the original volume of air. Hence $21 - 5{\cdot}5 = 15{\cdot}5$ per cent. of the air passing through the burners is the quantity of oxygen used to form sulphur and iron oxides. Therefore, each 15·5 vols. of oxygen used means 84·5 vols. of flue gas, *i.e.*, 100 grms. of ore mean 353 litres of flue gas.

The loss of nitre corresponding to 100 grms. of ore is $\frac{3 \times 48}{100}$ grm. sodium nitrate which would give a volume of nitric oxide $= \frac{3 \times 48}{100} \times \frac{22{\cdot}4}{85}$ litres $= {\cdot}380$ litre $= 380$ c.c. The loss of nitre should therefore give rather more than 1 c.c. of nitric oxide or an equivalent amount of any other oxide per litre of flue gas.* This calculation shows, therefore, that if a workable quantity of the nitrogen oxides is to be obtained, the volume of gas dealt with must amount to 10—20 litres. Now, although this volume of gas can be easily worked with when once condensed to a liquid, yet it would not be easy to carry gaseous samples of 10—20 litres from the sulphuric acid works to the laboratory. It was, therefore, necessary to carry out the first stages of the fractionation at the works themselves.

The flue gases consist of (1) a mixture of *nitrogen* and *oxygen* containing about 6·5 per cent. of the latter. This mixture does not liquefy under atmospheric pressure at the temperature of liquid air boiling in an open vessel (—189° C.); (2) *nitric oxide*, at —189° C., this is a white solid which has a vapour pressure of about 0·75 mm.; (3) *carbon dioxide* coming from the atmosphere; (4) *nitrous oxide*; (5) *nitrogen trioxide and peroxide*; (6) *sulphur dioxide*; (7) *sulphur trioxide and the vapour of sulphuric acid.* These latter substances 3—7 are all non-volatile solids at —189° C., and therefore it should be easy to separate them at that temperature from nitrogen, oxygen and nitric oxide by pumping away these three gases by means of a mercury pump. By this method, of course, the nitric oxide would be lost; but it seemed worth while to carry out a few experiments to determine the amounts of the other oxides of nitrogen which were present in the flue gases. In order to test the method of separation, a quantity of air containing a known amount of nitrous oxide—the most volatile of the other oxides—was passed through a glass spiral which was cooled to —189° C., by immersing it in liquid air. This spiral could be evacuated by means of a Töpler pump; and, after the whole mixture had passed through it, the spiral was evacuated, thus leaving only the solid nitrous oxide behind. The liquid air was then removed and the nitrous oxide pumped off and collected. Its volume was then measured and compared with the volume taken. Two results, which are given in Table I., show that the amount of nitrous oxide lost is not more than 0·003 per cent. of the whole volume fractionated. Hence this method should give almost the whole of the nitrous oxide, &c., contained in the flue gases.

Table I.

Vol. of air used.	N_2O taken.	N_2O found.	Vol. per cent. of N_2O lost.
1000 c.c.	1·31 c.c.	1·28	0·003
1200 c.c.	1·44 c.c.	1·42	0·002



* Mr. E. C. Thompson has kindly checked this calculation by direct measurements made on a sulphuric acid plant, and his figures agree fairly closely with this calculation.

The analysis of the mixture of substances which could be separated in this way from the flue gases still presented some difficulties. It was impossible to use aqueous absorbents until the sulphur dioxide had been separated from the nitrogen trioxide and peroxide so that this stage of the separation had to be done by means of a second fractionation. It was found that at —122° C. the melting point of crude ether, only the nitrous oxide and carbon dioxide were volatile, so that these two could be separated from the other bodies at that temperature. At —95° C. the sulphur dioxide begins to distill over, and at the same time nitrogen trioxide decomposes giving nitric oxide and peroxide, of which only the nitric oxide distills over. Hence, at —95° C. sulphur dioxide and nitric oxide could be pumped away from the peroxide and separated from one another by a second fractionation at —189° C. In this way, the flue gases were divided into the following fractions :—

1. Nitrogen, oxygen and nitric oxide.
2. Nitrous oxide and carbon dioxide.
3. Nitric oxide (from trioxide).
4. Sulphur dioxide.
5. Nitrogen peroxide and sulphuric acid, and possibly nitrosulphonic acid.

The analyses of these different fractions then presented no difficulty. Fraction (2) was measured, then mixed with oxygen (or air) and treated with caustic potash. (The addition of oxygen or air lowered the partial pressure of the nitrous oxide, and therefore lowered the amount dissolved by the potash.) The residue was then again fractionated at —189° C., and the nitrous oxide thus obtained pure. It was then measured, and its volume deducted from the original volume, the difference being the volume of the carbon dioxide. Fractions (3) and (4) required only to be measured. Fraction (5) which was left in the spiral, after the fractionation was complete, was shaken with air and water, thus forming sulphuric and nitric acids. The solution formed was titrated with N/10 barium hydrate, and the amount of barium sulphate formed was determined gravimetrically. From the figures thus obtained, the amounts of nitrogen peroxide and sulphuric acid could be calculated.

A method for analysing the flue gases having thus been worked out, experiments were made in a sulphuric acid works in order to see what conclusions could be drawn; and Dr. Messel, of Spencer Chapman and Messel, Ltd., very kindly gave me leave to carry out some analyses at the works in Silvertown. The plant which was tested consisted of two sets of chambers which had one Gay-Lussac tower each and a third one in common, and the samples were taken direct from the flue which led from this last tower to a large chimney. Two large carboys, fitted with corks and tubes and filled with water, served as aspirators, the volume of gas taken being equal to the volume of water run out, the pressure being shown by means of a small mercury gauge. The water was run out at the rate of about 5—6 litres per hour. In order to cool the gas thoroughly, it was passed through a spiral of the design shown in Fig. 1. The gas entered by the tap A,

and passed down the spiral and then out by the tap B. Since the volume at ordinary temperatures and pressures of the gas, which would be condensed in the spiral, might be considerably greater than the volume of the spiral, the bulb C was evacuated before each experiment and then the tap D closed. In this way after the whole volume of gas had been passed through the spiral, the taps A, B were closed, and then D opened, so that the condensed gas could, on warming up, expand into the bulb C.

The samples of gas were in some cases aspirated directly from the flue through the spiral, but, in the earlier experiments, a wash bottle containing concentrated sulphuric acid was placed between the spiral and the flue. By this means, the last traces of nitrogen peroxide and trioxide were removed, and all risk of the formation of chamber crystals in the bulbs was avoided. Since, however, it was found to be impossible to estimate the nitrous gas absorbed by the sulphuric acid—the quantity being so very small—in the later experiments the washing was omitted, and the gas taken direct from the flue through the spiral. In the earlier experiments the nitrogen and oxygen remaining in the spiral when the taps A, B were closed were not pumped out; and therefore, when the gases warmed up, any nitric oxide was turned into peroxide. But in the later experiments the spiral was evacuated by means of a small mercury pump while it was still in the liquid air, so that any nitric oxide that had been condensed remained unacted upon. The results obtained are given in Table II.

* Residual acidity is given as c.c. of N/10 baryta per 10 litres.

These 15 analyses fall into two classes. In the first seven experiments, the gases were washed with strong sulphuric acid (C.O.V.) before they passed through the cold spiral; while in the last eight cases, the gases passed direct from the flue into the spiral. The effect of this washing was that all the nitrogen peroxide and water vapour were removed, and therefore the sulphur dioxide, which was caught in the spiral, remained unacted on when the gases warmed up. In the last eight cases the sulphur dioxide formed chamber crystals in the spiral and bulb, and was, therefore, found as sulphuric acid. An attempt was made to preserve the sulphur dioxide from action by drying the gases with phosphorus pentoxide, but this seemed quite ineffective.

In considering the different nitrogen compounds found in the flue gases, it will be simplest to begin with the question of *nitrous oxide*. According to the exponents of the "chemical loss" theory, the loss as nitrous oxide should be a considerable proportion of the whole loss. The analyses, however, at once dispose of this possibility. It is true that nitrous oxide is found, but it seldom exceeds two parts in 100,000 (equivalent to four parts of nitric oxide per 100,000); and since the total loss is somewhat greater than one part per 1000 calculated as nitric oxide, the loss as nitrous oxide does not account for more than 3 or 4 per cent. of the whole loss. As such small quantities of nitrous oxide were found, its identification was somewhat difficult. It can, however, be analysed fairly accurately by measuring the contraction that takes place when it is exploded with hydrogen and by measuring the volume of nitrogen generated. The reaction with hydrogen takes place according to the equation:

$$N_2O + H_2 = N_2 + H_2O$$

Hence, it may be seen, that if the substance is nitrous oxide, both the contraction and the volume of nitrogen formed should be equal to the volume taken. In Table III. are given the results of three analyses which serve to show that gas was really nitrous oxide.

Table III.

Volume taken.	Volume of hydrogen added.	Volume after explosion.	Contraction.	Volume of nitrogen.
c.c.				
1·08	1·51	1·51	1·08	—
0·695	1·06	0·95	0·80	0·695
0·79	1·39	1·37	0·81	—

The analyses of the flue gases show therefore that Lunge was quite right in stating that the loss as nitrous oxide is very small ("Sulphuric Acid and Alkali," Vol. I., pp. 641, 708), and there is very little evidence to support a theory of reduction to nitrogen.

Taking next the question of the *nitric oxide* it is at first sight surprising that any is found. It has already been shown (page 150) that the vapour pressure of nitric oxide at —189° C. is too high for it to be separated at that temperature from the flue gases. The conclusion must, therefore, be drawn, that the nitric oxide was not condensed as such, but was formed in the bulb. Now, in the fractionation, the nitric oxide was found at two stages, namely, in the first fraction when it was obtained mixed with nitrogen, and in the later fraction when it was obtained together with the sulphur dioxide; being formed by the decomposition of the trioxide. In the earlier analyses these were not kept separate; but the two parts were analysed separately, for all the samples collected on Dec. 22. The nitric oxide found as such is given in column A., and that obtained from nitrogen trioxide is given in column B. It seems probable then that the nitric oxide was partly condensed with nitrogen peroxide as nitrogen trioxide, and that it was partly formed in the bulbs by the action of sulphur dioxide.

From the figures for the residual acidity (stated as c.c. of N/10 baryta per 10 litres) and for the barium sulphate (grms. per 10 litres), we may calculate the quantity of sulphuric acid in the residual acidity and also the quantity of acid oxides of nitrogen. The latter is best stated as c.c. of nitric oxide per 10 litres, and these figures are given in the table. From these figures, combined with those for the nitric oxide and those for the nitrous oxide (1 c.c. of nitrous oxide is equivalent to 2 c.c. of nitric oxide), we may calculate the total amount of nitrogen oxides found. The figures thus obtained vary from 3·10 to 7·05, and in the mean (4·93) account for about half the quantity of nitre lost, the total loss being equivalent to 10·8 c.c. of nitric oxide per 10 litres.

The conclusion to be drawn, therefore, from these analyses is that half the nitre is lost as nitrogen peroxide and trioxide, so that the loss is mainly mechanical, being due to incomplete absorption in the Gay-Lussac tower. This conclusion is supported by the experience of many manufacturers, who find that if two Gay-Lussac towers are used in series, instead of a single tower, the second tower catches a not inconsiderable amount of nitrous gases.

From the amounts of nitric oxide, nitric peroxide, sulphur oxides, and carbon dioxide, one can easily calculate the "total acidity." The results are given in the column headed "Total acidity calculated," the next column, giving the result found by the ordinary works method on the same day as my experiments, but not at the same time. The agreement between these figures is not particularly good, but the results are of the same order. It is to be noted that quite a high proportion of total acidity is due to carbon dioxide.

During these experiments one peculiar fact was noticed, but not fully explained. In the experiments 5, 6, and 7, of Oct. 13, the bulb seemed to contain a colourless gas, but when it was cooled with liquid air the solid that separated was red and not white, as one would expect. During the fractionation of 5 this red substance got into the pump, and at once acted on the mercury. Special precautions were taken in analyses 6 and 7 to isolate this red substance, but there seemed to be only a small quantity and it could not be identified. The flue gases on that day, however, contained a chloride, and it seemed possible that the gas was nitrosyl chloride NOCl. This substance, however, on being prepared pure condensed to a yellowish-white, and not a red solid, so no definite conclusion can be drawn. It is possible that nitrosyl chloride was present, and that its solid solution in the other substances was red; but such a supposition needs further proof. Unfortunately, this red substance was not obtained in any other samples.

The above method, though it gives definite results in regard to the nitrous oxide and the peroxide is, as already stated, unsatisfactory in so far as the nitric oxide cannot be estimated by means of it, since its vapour pressure is by no means negligible at —189° C. In order, therefore, to get the nitric oxide condensed its partial pressure above the condensed portion must be lowered, and this can be done in two ways—either by lowering the temperature or by dissolving out the nitric oxide by means of a liquid in which it is very soluble. As nothing was known regarding the solubility of solid nitric oxide, it was decided to try the effect of lowering the temperature, and it was found that its vapour pressure became very low <0·1 mm. at —193° C., a temperature easily attainable by boiling liquid air under diminished pressure. Hence, by working at —197° C., at which temperature nitrogen and oxygen condense very readily, the vapour pressure of nitric oxide and consequently its loss during fractionation would be negligible. It was therefore decided to make a few analyses by condensing the flue gases and fractionating them at a temperature not higher than —197° C. In this way it was expected that almost the whole of the nitric oxide would be left behind condensed in the bulb, so that an accurate estimation of the total loss of nitre would be possible. The only difficulty lay in measuring the volume of gas dealt with. Since the condensed gases would have to be fractionated by making them boil in the vacuum of a Fleuss pump, there was no means of measuring the volume of gas pumped off, so that the measurement had to be made by measuring the volume of the liquid formed at a known temperature; and then, from Baly and Donnan's (J.C.S., Vol. 81, p. 907) measurements of the densities of liquid nitrogen and

oxygen, the volume of gas corresponding to 1 cb. cm. of liquid could be calculated on the assumption that no contraction took place on mixing liquid oxygen and nitrogen. Now, at —197° C. the densities of these liquids are 1·2104 and 0·8171 respectively. Hence 2240 litres of a mixture containing x per cent. of oxygen and (100—x) per cent. of nitrogen would give a volume of liquid = $\frac{32x}{1{\cdot}2104} + \frac{28\,(100-x)}{0{\cdot}8171}$ c.c.

$= 3427 - 7{\cdot}83x$

Now, in the flue gases x = 6·5 per cent.

∴ 2240 litres of gas form 3376 c.c. of liquid

or 1 c.c. of liquid = 0·663 litre of gas.

The bulb used in these experiments is shown in Fig. 2. The lower part of the tube was about 20 mm. diameter and 120 mm. long, and was graduated in millimetres. In order to make the fractionation effective it was necessary that boiling should be regular, and it was found that a few tetrahedra of platinum, such as are used in a Beckmann's boiling point apparatus, quite prevented bumping and ensured steady boiling. After these had been introduced into the bulb, the volume of the bulb, up to different graduations, was determined by running in measured amounts of water. The volumes so obtained were corrected for the contraction that takes place on cooling the bulb to —197° C.

In order to measure the temperature, use was made of a long narrow bulb C, filled with oxygen under pressure and communicating with a manometer D. When this bulb was placed in liquid air some of the oxygen condensed to a liquid and the manometer then registered the vapour pressure of the oxygen. By measuring this pressure the temperature could be read off the vapour pressure curve for liquid oxygen. (See Travers Phil. Trans., 1903.)

In carrying out a fractionation the bulb and thermometer were put through holes in a rubber cork which fitted the mouth of a large cylindrical unsilvered vacuum vessel; and a tube leading to the flue was joined to the bulb at A. The vessel was then filled with liquid air and placed in a larger silvered vacuum vessel also containing liquid air. A Fleuss two-cylinder pump (two cylinders working in parallel) was then connected to the tube E, and the pump being set in action the air in the inner vessel was made to boil vigorously, thus lowering the temperature. In this way the temperature was lowered to —197° C., and then the tap A, being opened, the flue gas rushed into the bulb and there condensed to a cloudy liquid at the rate of about 1 litre of gas a minute, the pump being kept working slowly in order to keep down the temperature. When sufficient gas had condensed, the tap A was closed, and the inner vacuum vessel lifted out of the silvered one. Through the walls of the vessel one could then read off the volume of the liquid in the bulb, the temperature indicated by the thermometer being noted also. The Fleuss pump was then connected to the tap B, and this being opened the liquid was made to boil off into the vacuum of the Fleuss pump. By this evaporation the liquid air in the vacuum vessel was continually cooled, so that its temperature did not rise. When the whole of the liquid had evaporated the tap B was closed, and the bulb removed from the liquid air. The further analysis of the contents of the bulb was then carried out according to the methods employed in the earlier experiments. Since the condensed nitrogen and oxygen on being

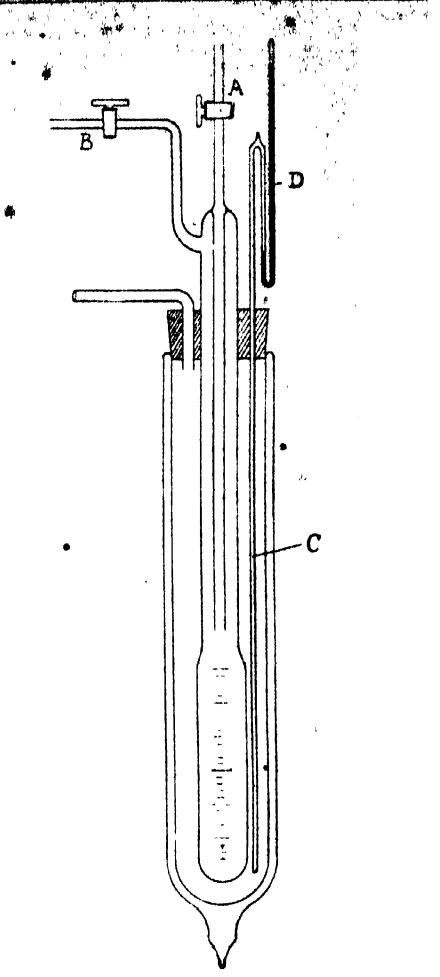

Fig. 2.

fractionated give off a vapour much richer in nitrogen than the liquid, towards the end of the fractionation almost pure oxygen was left behind and the last traces of this were not removed from the bulb. Hence, in the subsequent fractionation, nitric oxide was not usually found, as it acted on the excess of oxygen forming nitrogen peroxide. The results of four analyses carried out in this way are given in Table IV.

Table IV.

* Residual acidity is given as c.c. of N/10 baryta per 10 litres.

The last column in the table shows the total amount of nitrogen oxides found in the flue gases. It will be noticed that the fluctuations are very considerable, but, on the whole, the results agree with those already found in the earlier experiments. If, therefore, this method for the estimation of nitric oxide is a sound one, the conclusion must be drawn that only a small quantity of nitric oxide is present in the flue gases, and that a considerable proportion of the nitrous gases must be reduced to nitrogen. On the other hand, as only four analyses were carried out at the lower temperature, and these analyses show considerable fluctuations, there is hardly sufficient ground for stating that these analyses represent the average composition of the flue gases. Hence, since the question of the presence or absence of nitric oxide depends really upon the difference between these analyses and the earlier ones, one cannot safely say that nitric oxide is not present. This question can, however, be completely settled by carrying out a larger number of analyses at the lower temperature, and I hope to be able to do this during spring 1906.

The results of this research may be summed up as follows:—

(1) Only very small quantities of nitrogen peroxide and trioxide are reduced to nitrous oxide in the sulphuric acid chambers.

(2) About 50 per cent. of the total loss of nitre takes place owing to incomplete absorption of the nitrogen trioxide and peroxide in the Gay-Lussac tower.

In conclusion, I wish to express my thanks to Sir William Ramsay, Dr. Messel and Mr. E. C. Thompson for the kind interest they have taken in these experiments, and for the valuable advice and help I have received from them.

Discussion.

The Chairman said the results obtained seemed to do away with many theories which had been propounded. There was great reason to believe that the contention which Lunge had long made as to the real cause of this loss was correct. This was a remarkable instance of the perfection to which a chemical process could be brought, to some extent, in the dark. When the difficulty of bringing the enormous volumes of gas drawn from the chambers into contact with the acid in the towers was borne in mind, it was really marvellous that so very small a percentage as 0·01 per cent., which Mr. Inglis mentioned as constituting really the whole of the gas corresponding to a loss of 3 per cent. of nitre, should be all that escaped. The author was to be congratulated on the fact that he had succeeded in accounting for about 50 per cent., and, in some cases, for as much as 70 per cent. of this loss. There was still, of course, an unresolved residue, and he hoped in the course of the further researches some light would be thrown on that matter. It struck him as remarkable in looking at Table II. in the paper, that there was such a high percentage of carbon dioxide found. As the outflow of gases amounted roughly to 84½ per cent. of the volume of the air entering the plant, it might be thought the carbonic acid would go up to about 4·7, whereas Mr. Inglis found it was 6·5 to 7·5; in other words, very nearly 140 to 170 per cent. higher than it should be if it were merely to be accounted for by the reduction in the volume of the air due to loss of oxygen. He presumed there must be some reason for the excess of carbonic acid, possibly in the form of carbonaceous matter which adhered to the ore, and was burnt with it, or it might arise from the oxidising action of the acid on the coke in the towers.

Sir William Ramsay said what Mr. Inglis proposed would no doubt separate the nitric oxide from the nitrogen. After the mixture of gases was condensed the liquid nitrogen existing at the temperature of —197° had a very considerable vapour pressure, and with a good mercury pump that could be removed, leaving the nitric oxide behind; it was simply like boiling away the water from a saline solution, and leaving the salt.

Dr. Divers (the President) congratulated Mr. Inglis on the importance of the work he was doing. The result of it was one of the greatest additions to the knowledge of the processes of the lead chamber.

Mr. Oscar Guttmann said the author would probably find that the measurements of the quantity of gases dealt with were not reliable. He came to this conclusion, not by any discrepancy, but by the close agreement between the calculated quantity and that found. Anyone who had had to do with the measurement of gases, and especially by means of an anemometer, knew that discrepancies must of necessity be very large. A rough mental calculation showed him that the quantity of gas was calculated on the basis of 27 cb. ft. per second. Assuming the exhaust pipe to have a diameter of, say, 2 ft. 6 in., it would give a velocity of 5½ ft. per second, which is extraordinary. A large quantity of the oxides of nitrogen came out of the last chamber and passed to the Gay-Lussac tower for the purpose of being absorbed by means of sulphuric acid. A considerable portion of these gases was not absorbed in the tower, but passed out of the system; then the mere passage of air at the rate of 5½ ft. per second, or even at 1 ft. per second, carry away some of the oxides of nitrogen which thereby become a mechanical loss. This could easily be ascertained, and he would suggest that Mr. Inglis might direct his investigation in that direction. He could examine the gases at the inlet to the Gay-Lussac tower, and determine accurately the quantity of sulphuric acid that ran down, and the composition of the gases after they had passed the tower. He could thus find what loss there was in the Gay-Lussac tower, and whether and how much of it was due to decomposition or to mechanical abstraction. Mr. Inglis had based all his calculations on a loss of 3 per cent. of nitre on the sulphur burned, and no doubt that was a very reasonable allowance in the system in question; but he might mention that this loss had been much reduced in other systems, and it was not uncommon to have it amount to only 1·8 per cent.

Mr. W. Pearce said there was a difficulty in coming to any conclusion about a gas that varied so enormously in quality. He could quite understand that a number of the figures obtained were comparatively irreconcilable, by reason of divergence in the constitution of the gas. Another point was the very large quantity of resulting sulphuric acid, which went into consumption direct from the chambers, without having passed down the towers; a good deal of nitre was absorbed by that acid, and was lost in the process of distribution for sale. There seemed no chance of escaping such a loss. Those were practical difficulties that presented themselves to the sulphuric acid manufacturer.

Mr. J. K. H. Inglis, in reply, said the figures of carbon dioxide, referred to by the Chairman, were quoted from a table which he had not exhibited, but would appear with the paper, but he did not wish too much reliance to be placed in them; they were the result of the first experiments, and the later quantities found were much more constant. One point he had forgotten to mention with regard to sulphur dioxide, In the first experiments the gases were washed with sulphuric acid before being taken into the bulbs, and in that case he found a small quantity of sulphur dioxide amounting to about two parts per 10,000 in the flue gases. In later experiments, however, as this washing meant the loss of the nitrogen oxides, he decided that instead of passing it through sulphuric acid he would take the gas direct into the bulbs; thus any sulphur dioxide present was promptly attacked by the nitrogen peroxide and tetroxide. That was why the results given showed no sulphur dioxide.

In reply to Mr. Guttmann, concerning the errors in the measurement, based on the rate of flow of the gas, he believed his figures were quite correct; they were obtained for him by Mr. E. C. Thompson, but, as a matter of fact, they did not very much affect the question, because they did not come into the calculation at all. The two figures he gave were those obtained by calculating the rate of flow from the chamber, and the quantity actually found. These experiments were only made in order to see whether it was possible to calculate the rate of flow at the end of the chambers from the reactions at the beginning, and the agreement between the two sets of results—quite independent of their absolute value—proved that conclusively. Anyhow, the error was only 2 or 3 per cent., and in this sort of work 10 per cent. was not excessive. As to

a loss of 3 per cent. of nitre being rather high, he could only say that it was a fairly usual figure in that particular plant. In some cases, the loss had been reduced to about one-fifth of that, and he quite agreed that 3 per cent. was higher than it need be, but the question arose, was it worth while to put up extra plant in order to recover that amount of nitre? He should endeavour to carry out some of the work Mr. Guttmann suggested on the gases before they passed through the Gay-Lussac tower; the chief difficulty was that the gas then contained a large proportion of condensible gases, and, therefore, it was necessary to work with a small amount, or else with large tubes, which would not get choked. He also intended to experiment on the composition of the chamber gases themselves.

CARBURETTED WATER GAS IN THE BUNSEN BURNER.

BY MASUMI CHIKASHIGE.

The defects of water gas as a fuel in the chemical laboratory were experimentally tested some time ago, in Kyoto, Japan, by H. Matsumoto and the author. The results were given in a paper read before the London Section of the Society of Chemical Industry, and printed in the Journal of the Society for 1904 (page 50). There being no coal gas available for the use of the Kyoto University laboratories, a method of preparing carburetted water gas, much on the lines followed by Prof. V. C. Lewes, was devised by a committee appointed by the University, and including the author. In this process, heavy petroleum oils are injected with steam into the water-gas generator filled with ignited coke. The gas produced is passed through a superheater, loosely packed with fire-bricks, and then through a scrubber, after which treatment and purification it enters the gas-holders. It is not now the purpose of the author to go into the details of this process, as worked out by the committee. His object is only to make known the behaviour of this gas when used as a laboratory fuel.

The mean composition of the gas does not differ much from that of coal-gas;—

	Vols. per cent.
Heavy hydrocarbons	5·3
Methane	16·8
Hydrogen	51·7
Carbon monoxide	15·4
Carbon dioxide	0·6
Oxygen	0·5
Nitrogen	9·7

There have been, occasionally, some wide deviations from the mean composition, one of which will be noticed in the next paragraph. Only a brief account of the behaviour of the carburetted water gas is necessary, because this hardly differs from that of coal gas to which it approximates in composition.

Partial combustion of the gas.—The carburetted gas was tested in the same way as simple water gas itself had been, by the Smithells and Ingle's apparatus, in order to find out what are the proportions of the constituents of the partially-burnt gas. Two samples were examined in this way—one (*a*) which had very closely the mean composition shown in the table, and another (*b*) which deviated largely from that in having about 20 vols. per cent. of carbon monoxide, and only 3 vols. per cent. of heavy hydrocarbons. Side by side with the results obtained are placed those given in the former paper.

	Coal gas. (Sm. & Ing)	Carbur. gas. *a*	Carbur. gas. *b*	Water gas.
Water	14·9	16·7	16·7	17·0
Hydrogen	10·9	12·8	12·1	20·0
Methane	trace	0·9	0·9	0·8
Carbon dioxide	2·6	3·1	3·2	3·8
Carbon monoxide	10·2	10·4	9·8	10·5
Oxygen	—	—	—	0·1
Nitrogen	60·3	56·1	57·8	34·8

The carburetted gas in burning soon becomes similar to burning coal gas in composition. Even the (*b*) sample did so, notwithstanding the defects in its composition at first, and in consequence of the fact that the hydrocarbons present in it made it possible to let in, through the Bunsen tube, a sufficient proportion of air without causing the flame to descend the tube as it would then do in the case of unenriched water gas (see former paper).

Size of the Bunsen flame.—It was pointed out in the former paper how much greater a flow of gas was needed to produce with non-carburetted water gas the same sized flame as that given by coal gas in the Bunsen burner. To the numbers there given can now be added that for carburetted gas. To get the usual flame, one about 15 cm. long, the flow of gas per hour has to be in the case of—

	Litres.
Coal gas	120
Water gas	200
Carburetted gas	160

Therefore, the triangular orifice of the ordinary Bunsen burner for coal gas requires to be only slightly enlarged; that is, in the proportion of 4 to 3, in order to get the same sized flame with the carburetted water gas.

Effects of the flame upon laboratory vessels.—The carburetted gas has no action upon copper, platinum, or porcelain vessels, greater than that of coal gas. A porcelain crucible placed in the Bunsen flame only gets a deposit of carbon on it when it is placed so low as to touch the inner cone of the flame. Similarly, a platinum vessel only loses in weight in the flame when kept for a long time touching the inner cone, or when the flame is surrounded by a muffle.

Effects upon the air.—The products of the nearly finished combustion of the carburetted gas being, unlike those of plain water-gas, the same in composition as those of coal gas, the use of the gas in insufficiently ventilated laboratories is not more injurious to health than that of coal gas.

DISCUSSION.

The CHAIRMAN said he had used the apparatus, manufactured by Müller, of Birmingham, in which air was enriched by passing it through light hydrocarbons. It was at first rather difficult to manage on account of the varying proportions of the amount of air to the mixture, and also because of the shortness of the flame, but he had no trouble from attacks on platinum vessels, or anything of that kind.

Sir WILLIAM RAMSAY said his only experience of the use of small gas plants was in India, where the usual device was the introduction of oil gas, the method most in vogue being that of dropping the oil into a red-hot retort. The difficulty was that the life of the retort was not long, only six or eight months, and the trouble of constant attendance; but in India, where labour was cheap, that gave little trouble. A boy looked after it, and regulated the dropping; the gas went into a small gas-holder, and was thence distributed.

Mr. T. C. CLOUD said he had used Müller's machine for 28 years in a large chemical laboratory in connection with a metallurgical establishment. This machine was well worth bringing to the notice of the Society, because a number of the members were in places where coal gas was not available. He had not found any difficulty in the working of the machine provided it was placed in a cool situation—the best place was in an underground room or cellar. One slight addition was required, an extra small pipe should be brought to the laboratory from the air chamber, so that the final adjustment of rich gas and air could be made in the laboratory itself, instead of going down to the machine. The gas was made slightly rich at the machine, and then, in the laboratory itself, a small amount of air was allowed to pass in to a mixing reservoir, from which the gas was distributed. They had a machine capable of supplying about 120 lamps, and had no trouble. They used the same Bunsen burners as were used for gas without any alterations. There was no action on platinum or other vessels.

Dr. H. G. COLMAN said he could confirm the [illegible] experience with regard to the use of carburetted [illegible]

gas. He had frequently had occasion to use, for laboratory purposes, ordinary carburetted water gas, now largely made in this country, for admixture with coal gas, and there was no difficulty in the matter, although the percentage of carbon monoxide might rise much higher than that given in the paper, sometimes amounting to 32 or 33 per cent. With regard to the figures as to the interconal gases, when the gas was burnt in a Smithells' separator, there was a valuable series of researches on this subject which had recently appeared in the Journal für Gasbeleuchtung, 1905, 48, 1035; 1057; 1081 and 1107; and largely confirmed the figures given in the paper.

Mr. W. F. REID said he had found petroleum made a good substitute. In a private laboratory it was rarely worth while to put up an installation for water gas, but he found a blue petroleum flame would do most of the work he required. There were several lamps now in the market which would produce a perfectly blue, and, therefore, smokeless flame. The one he most used was the Primus lamp, burning ordinary heavy petroleum oil. They might recollect that that was the lamp which Nansen used on his Arctic travels. The lamp gave no trouble, and a crucible could be got nearly white hot with it.

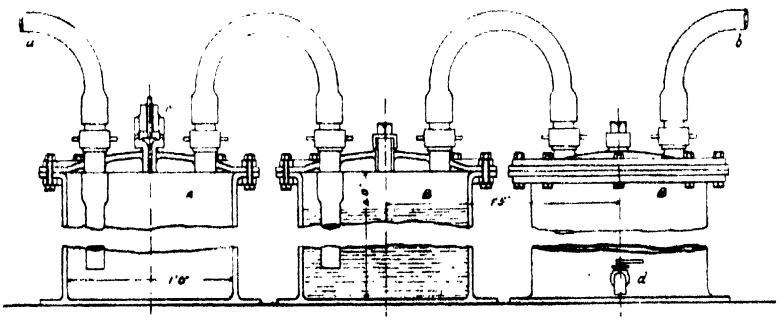
Mr. OSCAR GUTTMANN sent a sketch of an apparatus which he has used in laboratories for more than 20 years. It consists of three cylinders, made of lead or iron. Cylinder A serves as a regulator for the air. This can be either compressed air or produced by a gas-holder. The air arrives through the tube *a* and is used through the tube *b*. A small dead-weight safety valve *c* insures that the pressure of air, entering through the gas producers, has always the same pressure. There can be one or two gas producers B B, which are constructed in exactly the same way as the cylinder A, with the exception that, instead of the safety valve, they have a cap for filling in gasoline. The cylinders can be emptied by means of the tap *d*. This apparatus has always given complete satisfaction.

THE REMOVAL OF NITROUS ACID FROM CONCENTRATED NITRIC AND SULPHURIC ACID. *

BY OSWALD SILBERRAD, PH.D., AND BERTRAM J. SMART.

It has been frequently observed that the removal of nitrous acid presents much greater difficulties in presence of concentrated acids than in dilute aqueous solution. The following experiments were carried out to determine to what extent the reaction between nitrous acid and amines or amides occurs in concentrated acids, and to throw some light on the nature of the reactions which occur under such conditions. For the experiments, nitric acid containing a small percentage of nitrous acid was taken, either alone or in admixture with sulphuric acid. Various reagents, which are known to react readily with nitrous acid in aqueous solution, were added in the form of powder to the concentrated acid, and allowed to stand at ordinary temperature. From time to time, the amount of nitrous acid present was determined by titration with potassium permanganate.

The following table shows the results of a number of such experiments:—



Rate of removal of nitrous from nitric acid.

Acid.	Reagent.	Percentage of nitrous acid.		
		0 hours.	5 hours.	24 hours.
Nitric acid, sp. gr. 1·42	Urea	0·075	0·00	0·00
„ 1·50	Urea	0·915	0·48	0·52
„ „	Lead peroxide	0·915	0·76	0·87
„ „	Hydrazine sulphate	0·915	0·84	0·17
„ „	Oxamide	0·915	0·90	0·17
„ „	Methylamine nitrate	0·996	0·96	0·93
„ „	Aminoguanidine nitrate	0·996	0·76	0·93
Mixture of:—				
Sulphuric acid, H_2SO_4, 60·6 parts	Urea	0·081	0·076	0·078
Nitric acid, HNO_3, 37·2 „				
Water, 2·2 „				
„ „ „	Urea	0·317	0·292	0·298
„ „	Lead peroxide	0·317	0·261	0·292
„ „	Hydrazine sulphate	0·317	0·093	0·084
„ „	Methylamine nitrate	0·347	0·342	0·340

The addition of hydrazine sulphate was accompanied by explosions, a smell of azoamide being observed; the formation of azoamide is evidently to be traced to the action of the nitrous acid upon the hydrazine, in presence of strong acids.

It is seen that, with the exception of hydrazine sulphate, the reagents are very inert towards nitrous acid in presence of concentrated nitric acid, although they react readily in dilute solution. It appears that the reaction takes place between the nitrous acid and the ions formed by the salt of the amine or amide, and is not due to the salt itself.

The observation of Franchimont (Rec. trav. chim., 1883, 2, 96; 1884, 3, 219) that urea nitrate decomposes with evolution of carbon dioxide and nitrous oxide, was confirmed in the present work. Analyses of the gases evolved gave the following results:—

* Taken as read.

	CO_2.	N_2.	N_2O	NO	O_2.
From nitric acid sp. gr. 1·42	44·8	55·0	—	0·2	—
" " 1·50	39·6	38·9	19·8	—	—
From a mixture of nitric and sulphuric acids ..... —	34·7	37·4	26·4	—	—

Ammonium salts were found in the residual acids, from which it appears that the primary action of the nitric acid is to hydrolyse the urea, forming ammonium nitrate, which is then dehydrated to nitrous oxide.

Our thanks are due to the Explosives Committee for permission to publish these results.

DR. G. H. BAILEY IN THE CHAIR.

IRONMOULDING OF CLOTH IN THE LOOM.

BY WILLIAM THOMSON, F.R.S.E., F.I.C.

The manufacturer, and more especially those engaged in the production of heavily sized grey cloths, find from time to time that, on leaving the warp in the loom overnight, the reeds become rusted, and on commencing to weave in the morning a rust or iron-mould band of from 5 to 9 in. wide is formed across each piece of cloth. Many reasons have been given as to the cause of the rusting. Most commonly it has been attributed to the employment of excessive quantities of salts in the size, such as magnesium or zinc chlorides. These might have some action, but the constituent of the size which would be most likely to cause rusting of the reeds, is a substance frequently found in solutions of zinc chloride employed for sizing purposes, *viz.*, chlorates existing as potassium or sodium chlorate. (See Lunge, this J., 1885, 32.)

Zinc chloride is prepared chiefly from zinc ashes, the refuse from galvanising works; this refuse contains ammonium chloride, metallic iron and iron oxide, zinc and zinc oxide. These ashes are dissolved in hydrochloric acid forming zinc chloride and ferrous chloride. When nearly all the acid is neutralised, to remove the iron requires its oxidation to the ferric state. For this purpose I (as the deviser of the first process for the manufacture of zinc chloride from this refuse) employed a solution of bleaching powder. It had this disadvantage, however, that a combination took place between the nitrogen of the ammonium chloride present, and the chlorine of the bleaching powder forming, presumably, nitrogen trichloride, which exploded with a series of somewhat alarming detonations which, however, did no damage. This was overcome by employing sodium or potassium chlorate, and these are most commonly used at the present time. Unfortunately, the calculated quantity of chlorate is not sufficient to oxidise all the iron present in the zinc chloride solution; in fact, ferrous salt can exist in presence of an excess of chlorate even in hot solutions of the zinc chloride, and it is only after the chlorate has been added in considerable excess that all the iron becomes oxidised. Most of the zinc chloride solutions of commerce contain quantities of sodium or potassium chlorates varying from 0·1 to 1·4 per cent., and these salts rapidly rust the steel reeds of the loom when they come in contact with them.

It is obvious further that the greater the quantity of such zinc chloride solutions contained in cloth the greater will be the oxidising action of the warp threads on the reeds with which they remain in contact. Pure zinc chloride and pure magnesium or calcium chlorides, which are usually contained in heavily sized warps, have little oxidising action on the iron of the reeds, and warps containing these pure salts, even in large quantity, will not produce iron-moulding of the warp or the cloth.

It becomes, therefore, important to find some agent to oxidise the iron in zinc chloride solutions, which will not remain in it afterwards and injuriously affect the reeds. Bleaching powder when so employed does not rust the reeds, whilst it has the additional advantage that the lime combines with any sulphuric acid which may be present as sulphates forming calcium sulphate, which becomes largely precipitated with the ferric oxide after neutralising. A good plan for oxidising the iron in the zinc chloride solutions is to add to the hot solution the quantity of manganese dioxide (preferably that contained in Weldon mud) required to oxidise the iron present. The manganese dissolves, and is afterwards found in the zinc chloride solution, but it does not produce rusting of the reeds, and does not injuriously affect the colour of the cloth in the small proportions present. Potassium or sodium manganate or permanganate may be used, as these substances need not be in excess to complete the oxidation of the iron. Chromic acid or potassium bichromate may also be used, the reduced chromium being removed with the iron. From an economical point of view, it might be well to oxidise most of the iron present with sodium chlorate, and complete the oxidation by means of chromic acid, potassium bichromate or manganese dioxide.

Sodium peroxide acts very efficiently as an oxidising agent, and the caustic soda formed partially neutralises the liquor, and thus aids in the precipitation of the iron peroxide, whilst the resulting zinc chloride solution does not oxidise the reeds. Hydrogen peroxide acts very well as an oxidising agent, and any excess would doubtless be removed on drying the warp, but if a trace of this substance be left in the liquor it produces rusting of the reeds almost immediately.

The following table shows the quantities of the different oxidising agents required to oxidise 1 lb. of ferrous into ferric oxide in fractions of 1 lb.

	lb.
Manganese dioxide	0·604
Bleaching powder (35% avail. Cl.) ..	0·140
Sodium chlorate	0·346
Potassium chlorate	0·263
Chromic acid	0·452
Sodium bichromate	0·606
Potassium permanganate	0·439
Sodium peroxide	0·541
Hydrogen peroxide (containing 3·04% H_2O_2)	0·236

I made a number of experiments by putting knitting needles on cloth and on blotting paper soaked with the various substances, and observing how rapidly rusting took place. Chlorates in a neutral solution did not produce rusting, but when the solution contained a trace of acetic acid, rusting took place rapidly, and as size nearly always contains free acid, it may be taken that the conditions necessary for the rusting of the reeds always exist in the warp if chlorates be present in the size.

The following table shows the influence of different substances in producing rusting of the reeds. The experiments were continued for 48 hours in solutions made acid to litmus paper with acetic acid.

Pure zinc chloride	did not rust
" magnesium chloride	"
" ammonium chloride (saturated solution)	4 hours
" sodium chlorate (saturated solution)	10 minutes
Solution of zinc chloride containing 1 per cent. of sodium chlorate	10 minutes
Ditto, but containing 0·25 per cent. of sodium chlorate	4 hours
Ditto, containing 1 per cent. sodium chlorate, but as *free acid*	did not rust

The following gives the results of two analyses of samples of zinc chloride solutions for sizing purposes:—

Analyses of zinc chlorides.

	I.	II.
Zinc chloride	44·63	44·94
Zinc oxide	0·38	1·49
Ammonium chloride	2·05	absent
Sodium sulphate	1·27	trace
Sodium chlorate	0·28	0·31
Water	51·39	53·26
	100·00	100·00
Specific gravity at 60° F.	1·5265	1·5300
Equal to degrees, Twaddell	105·3	106·0

In conclusion, I have to thank my assistant, Mr. Charles Norman Exley, for the ability and care he has shown in carrying out this investigation.

DISCUSSION.

Mr. F. A. ERMEN said he had a case which somewhat resembled the oxidation of iron on cloth. He was given some bronze printing on calico to investigate, which had entirely turned green, and he found that this bronze had been printed on with the help of gum arabic. The calico contained a small amount of zinc chloride, and he presumed the oxidation was brought about by the free acids always present in gum arabic and which produced a chemical action when the cloth had been kept in a damp place. He might add that cloth kept in a dry place was not so affected.

Dr. R. S. HUTTON did not think Mr. Thomson had included another class of zinc chloride solution, *viz.*, that produced by electrical means, although a considerable amount came from this source as well as from other sources. He presumed that no such difficulties were met with where no oxidising agents were employed for the separation of iron as happened in the process to which he (Dr. Hutton) had referred.

Some time ago he had a number of complaints of oil stains on white cloth, which, on investigation, were attributed to some trace of iron in the oil used for the machinery, but they had never assumed that the stains were due to the chemical action to which Mr. Thomson had referred. In cloths with an alkaline tendency this action did not take place.

Mr. E. A. FASNACHT said in a recent paper by Prof. Dunstan and others on "The Rusting of Iron" (J.C.S., Oct., 1905; this J., 1905, 1235), it was shown that in all probability hydrogen peroxide was produced, although they were not able to detect it. Prof. Dunstan considered that chromic acid prevented the formation of rust, and that it did so by decomposing the hydrogen peroxide. It was somewhat remarkable that chromic acid prevented the rusting of iron and that chlorates did not.

Mr. W. H. COLEMAN thought the paper showed that chemical manufacturers should leave no deleterious matters behind in their products which might cause subsequent trouble to the users. He considered that blowing with air alone was one of the most difficult means of oxidising iron compounds.

Mr. WM. THOMSON, in reply, said the bronze powder referred to by Mr. Ermen hardly came under the same category as ironmould. The powder would become green and oxidise by moisture alone, aided perhaps by a little free acid in the gum. Dr. Hutton referred to zinc from other sources. As a matter of fact the chief source of the zinc chloride was from zinc ashes. A small quantity was, however, produced by electrical means which was very good for sizing purposes, and there was also a certain quantity produced from spelter which was free from ammonium chloride, but that did not remove the difficulty, as iron must still be separated from the zinc chloride solution by some oxidising agent. Oil stains on cloth were caused by the metallic iron present in the oils from the machinery, which was liable to form rust if the cloth were left in a damp condition for some time. The presence of alkali prevented rusting, and a trace of acid would aid oxidation. With regard to the hydrogen peroxide theory, chromic acid, which Prof. Dunstan thought decomposed hydrogen peroxide and thus prevented rusting, probably formed a very thin film of magnetic iron oxide on the iron. He had found that a thin coating of the magnetic oxide had been formed on iron which had been painted with red lead. This coating was equivalent to "Barffing," preventing the iron from rusting easily after removing the paint; chromic acid would probably have the same effect.

A RE-DETERMINATION OF THE CONSTANTS OF CARNAÜBA WAX.

BY LIONEL GUY RADCLIFFE.

A sample of Ceará wax melting at 84° C., was used for the experiments, and also a bleached sample, which melted at 61° C. The figures recorded for the acid value vary from 4 to 8, and O. Eichhorn (Zeits. anal. Chem., 1900, 39, 640—645; this J., 1901, 74) states that by dissolving 3 grms. of the wax in 120 c.c. of boiling amyl alcohol he obtained an acid value of 9·71. A repetition of the above method gave for the Ceará wax 5, and for the bleached sample 0·56. The saponification values stated by various observers vary from 79 to 95. A series of experiments were made in order to ascertain which method gave the maximum value, and it was found that by treating 5 grms. of the wax with 60 c.c. of amyl alcohol and 50 c.c. of ordinary alcoholic potash (60 grms. to the litre) and boiling for six hours, the figure 88·3 was obtained, the bleached sample giving 33 to 34. The iodine value by Wij's method was, after 24 hours, 13·17 per cent.

The values obtained on one and the same sample of Carnauba wax are:—

Melting point (in capillary tube)	84° C.
Acid value	2·9
Saponification value	88·3
Ester value	85·4
Iodine value	13·17

I have pleasure in expressing my thanks to Messrs. E. Barber and W. H. Maddocks for their assistance in the above work.

DR. RUSSELL W. MOORE IN THE CHAIR.

THE GRADING AND USE OF GLUES AND GELATINE.

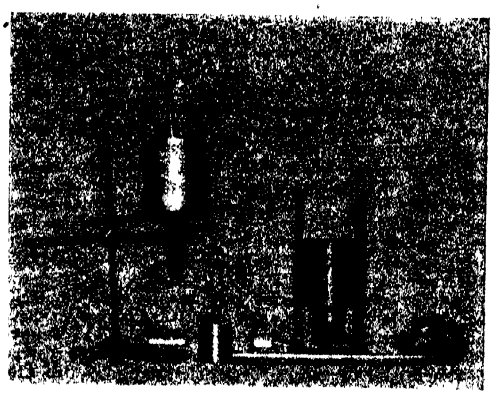
BY JEROME ALEXANDER.

In this paper it is desired, firstly, to describe a connected series of selected tests which may be run consecutively and used as a basis of grading; secondly, to define standards for use in these tests; and, thirdly, to give some practical hints on the proper selection and use of glues and gelatines. For convenience, the product will be referred to as "glue," gelatines being regarded as very clean or high grade glues, and the suggestion of Rideal, followed by Watson and others, will also be observed, spelling the name of the commercial article gelatine, and that of the chemically purified substance gelatin.

Before describing the tests, it is necessary to consider the different kinds of glue met with in commerce. H. J. Watson, in an excellent article on "Glue and Glue Testing" (this J., 1904, 23, 1189), has given a classification of glues, based partly upon the nature of the raw material

used, and partly on the way in which the "runs" or successive boilings are combined; but, as he remarks, "this grouping does not by any means exhaust the variations in these products." I think that a more thorough understanding of the differences in glues may be obtained if we consider, first, the various raw materials or glue stock; second, the treatment of the glue stock before boiling; and, third, the separation or blending of the various "runs." The chief sources of glue are bones and trimmings, cuttings and fleshings from hides and skins. Sinews, feet, tails, snouts, ears and horn pith are also largely used. The various parts from cattle, calf, goat, sheep, pig, horse and rabbit all yield characteristic glues having peculiar properties. The liquid glues obtained from the heads, bones and skins of fish form a class of their own, and are not here considered.

The treatment of the stock depends upon the technique of the particular factory, and the use for which the finished glue is intended. In some factories bones are boiled without even washing; in others, most of the grease is steamed out or removed by volatile solvents. The clearest and best bone glues are obtained by leaching the bones with dilute acid which dissolves out the lime salts and leaves the gelatinous matters. Such crushed leached bone is sold as a glue stock under the name of osseine. Hide pieces, sinews, osseine and leached horn pith are limed until properly "plump"; the subsequent treatment before boiling varies, being usually regarded as a trade secret.



One extraction of the stock does not exhaust all the glue in it, so it is necessary to make a number of consecutive extractions or "runs," as they are called. The condition of the stock, the temperature and time of boiling, and the apparatus employed are the main factors controlling the proportion of glue in each run. Sometimes as many as ten or fifteen runs are taken from the same kettle of stock, and these runs may be finished alone, or blended with each other or with runs from other kettles containing perhaps different kinds of stock. It will be readily seen that the kinds of glue are practically unlimited in number, as indeed the great variation in appearance would seem to indicate. But in glue, above all things, appearances are very deceptive. Even after a manufacturer has finished his glue, he is obliged to test it in order to establish the grade of his finished product.

To the chemist or analyst, glue presents itself in the form of sheets, flakes, nodules, small grains or powder, varying in colour from black to white and all shades of brown and yellow. It may be clear, cloudy or opaque. How shall a value be assigned to each glue? Purely chemical tests, as at present known, are for the most part of little value. The determination of water is without much practical significance, for all desired is that the glue be commercially "dry." The presence of any considerable amount of phosphates in the ash is supposed to indicate that the glue was made from bone stock.

Numerous articles have appeared from time to time in the journals and in technical books, describing methods and instruments for testing glue, and while many of these are good as far as they go, the writer has as yet seen none that may be regarded as complete. What is most striking is the lack of glue standards or units of measurement.

Thin blown glasses about 8—8·5 cm. high and 5·5 cm. in diameter are convenient for tests. 25 grms. of each glue to be tested is broken into small pieces and soaked in 100 c.c. of water until softened (overnight if possible); and at the same time a number of standard glues, described later on, are treated in like manner. All the glasses are at the same time placed in a water-bath, heated to 80° C., and stirred until a perfect solution is obtained. More or less than 25 grms. per 100 c.c. can be used as long as the standards and unknown glues are all treated alike. The *reaction* is determined with litmus paper. In cases where the degree of acidity or alkalinity is desired, a separate titration is made.

Viscosity or running test.—Keeping the temperature uniform, the viscosity is determined by running the hot solution from a pipette, noting the time of efflux by a stop-watch. The relative viscosities are thus fixed in seconds. We use a pipette of 45 c.c. capacity, which will permit the efflux of hot water from the glue bath in exactly 15 seconds. After each determination, the pipette is washed with hot water, and care must be taken that no partially evaporated glue or slime clogs the outlet. While running, the pipette may be kept in a specially constructed thermostat. More complicated viscosimeters, as Engler's or the Rideal-Slotte instrument, may, of course, be used.

Viscosity Pipette in Thermostat. Jelly-strength Tester with Cups.

Care must be taken to make two pipettes that will give concordant results. The size and shape of the outlet, and the length and diameter of the effluent tube are the chief factors controlling the time of delivery. I have tried metal tips, but find them unsatisfactory, for it is not easy to duplicate them exactly, or to make a good connection with the glass.

The pipette that was finally adopted as standard has the following dimensions:—

Capacity	45 c.c. of water at 80° C.
Internal diameter of effluent tube..	6 mm.
External diameter of effluent tube	9 mm.
Length over all of effluent tube ..	7 cm.
Smallest diameter of outlet (about)	1·5 mm.
Outside diameter of bulb	3 cm.
Length of bulb	9·5 c.m.
Length of upper tube	22 cm.

The efflux hole was made by cutting the effluent tube square across, and holding it vertically in a Bunsen flame with constant rotation. As the glass softens, the hole gradually draws together, and after a few trials can be brought to the desired size. It is desirable to have the lower graduation point just where the effluent tube joins the bulb, for otherwise in glues of high viscosity there is much uncertainty caused by dribbling of the last few drops.

The most convenient thermostat is a simple water-bath. The projecting effluent tube is protected by a mica cylinder through which the end point is observed. When the thermostat is used a small piece of rubber tubing controlled by a pinch cock is slipped over the upper end of the pipette, or a glass stopcock may be fused on.

The *odour* of the hot solution is then noted, and the glue rated as sweet or "off." Decomposition is readily detected, although it is often masked by phenol or ethereal oils. Besides, the smell gives some indication of the stock from which the glue was made.

Grease.—The glue solution is painted on a piece of white paper with a little aniline or dry colour, and spots of "eyes" appear roughly proportionate to the amount of grease present.

Foam is determined by agitating the solution with a rod or mechanical agitator. An egg beater serves very well. Like grease, foam is estimated on a comparative basis.

Comparative set.—The glues are then taken from the bath, allowed to cool, and the comparative set or speed with which the jellies harden is noticed.

Jelly strength or "test."—When the jellies have reached the room temperature, the jelly strength or "test" is determined. For speed and perhaps also accuracy, I prefer the "finger test," and grade the jellies comparatively by pressure with the finger tips, the unknown glues naturally grouping themselves as stronger or weaker in jelly than the several standards. Notwithstanding the personal equation, expert operators obtain much more uniform results in this way than are given by the various mechanical devices. A special instrument for the determination of jelly strength will be referred to later.

Melting point.—The melting point of the jelly as described by R. Kissling (Chem. Zeitung, 1901, **25**, 264; see this J., 1901, **21**, 509) is also of considerable value, for, generally speaking, it is proportionate to the jelly strength. It may be determined by the simple apparatus described by N. Chercheffsky (Chem. Zeitung, 1901, **25**, 413; see this J., 1901, **25**, 731).

Strictly speaking, a glue jelly has no absolute melting point, for it softens up gradually and shows no sharp line of demarcation between solid and liquid. I have tried to determine the melting point by filling a small test tube and observing the temperature at which shot of the size known as B.B. would sink, but the results were very uncertain and then only comparative. Perhaps, the best way is to put the test glasses back into the water bath, and gradually raise the temperature, noting comparatively how the jellies melt.

Binding or adhesive strength.—For this there is no one test that can have a general application; the glue must be tried under actual working conditions. It stands to reason that if a glue is to be used to hold clay to paper, it is of small interest what its binding strength is on mahogany, maple or porcelain blocks. Very often, in fact, a glue that will size paper perfectly will not make a joint.

Keeping properties.—The glasses are then allowed to stand uncovered at room temperature for several days to observe the relative keeping qualities of the jellies. If the keeping property under special conditions is desired, these conditions are simulated.

Standards.—The choice of standards is a very important matter, for once they are taken all unknown glues are measured by them. Few published results of glue tests can be used for comparison, because seldom, if ever, have any two investigators worked on the same glue or glues, which have been described sometimes by their cost, sometimes by the stock from which they were manufactured, and upon which only partial determinations were made. That definite standards will simplify and harmonise the grading of glue is self-evident.

We arbitrarily fix 16 nearly equidistant grades and assign to them values running from 10 to 160, allowing 10 points between each grade.

160	80—1 3/8
150	70—1 1/2
140	60—1 5/8
130—A extra	50—1 3/4
120—1 extra	40—1 7/8
110—1	30—2
100—1 X	20
90—1 1/4	10

Opposite these grades I have set the corresponding grades long ago established by Peter Cooper, which are used for comparison by many American manufacturers and dealers.

The following determinations were made to establish such definite figures on our standards as will enable anyone to pick out glues of the same characteristics, so that we may all speak in the same language as it were.

The higher standards from 60 and upwards, are neutral hide glues, clear, clean, well made, free from any odour of decomposition, and practically free from foam and grease. For the lower standards bone glues were chosen, because most low test glues are bone glues and, furthermore, low test hide glues usually show abnormal viscosities.

The viscosities were taken as above described, with solutions containing 25 grms. of standard glue to 100 c.c. of water. For the standard viscosities I have taken the average of numerous laboratory tests; and inasmuch as standards of the same jelly strength are apt to vary somewhat in viscosity, I have indicated what, according to my experience, are the reasonable limits of such variations. (See table.)

Standard	Viscosities (in secs.) at 80° C. solution 25-100.	Allowable variation of viscosities (in secs.).	Jelly strength (in ozs.) at 10° C.	Jelly strength (in grms.) at 10° C.
10	15½	± ½	—	—
20	16	± ½	—	—
30	16½	± ½	—	—
40	17	± ½	60	1701
50	18	± ½	82	2324
60	19	± ½	104	2948
70	20	± ½	126	3572
80	21	± ½	148	4196
90	22	± ½	170	4820
100	23	± ½	192	5443
110	24	± ½	214	6067
120	25	± 1	236	6691
130	26	± 3	258	7314
140	28	± 5	—	—
150	34	± 8	—	—
160	40	± 12	—	—

To determine standard jelly strength the "shot" test was found unreliable, and a special instrument was devised. It consists of a brass cylindrical vessel supported like a gas tank by four vertical rods, against which it slides with almost frictionless roller bearings. This brass cup is allowed to rest on a truncated cone of jelly of definite size, composition, and temperature; and shot are gradually poured into the cup until a definite expression of the jelly is observed. Beneath the cup are two vertical adjustable brass uprights 3·5 cm. high, connected with an electric bell circuit; so that when the cup reaches their level, it completes the circuit and the bell rings.

The weight of the brass cup *plus* the weight of the added shot gives a figure which expresses the jelly strength.

The jellies were cast in brass cups 6 cm. high, 5·5 cm. in diameter at the open top, and 5 cm. at the bottom, which is closed with a tight fitting external friction cap. The jellies are removed by dipping the cups for an instant in hot water, taking care that no material loss results. The liberated truncated cones should be 4·5 cm. high, the cups being filled only to that level. They are placed in a thermostat until they reach the required temperature, 10° C.

In order that the various standards may be used for cross reference, I am now preparing a table which will define the jelly strength of each standard in terms of every other standard. For instance, standard 90 made up 22 grms. to 100 c.c. water has the same jelly strength as standard 80 made up 25 grms. to 100 c.c. In this way it may be possible to do away with a multiplicity of standards; at any rate the table will still further define the standards.

Discussion of results.—Now, supposing that we have run a careful test, and have a series of accurately determined figures, what do they mean? Do they express numerically the value of the glue for any work? Most assuredly not. E. G. Clayton (this J., 1902, **21**, 670), after carefully comparing many of the methods used and the resulting figures, says: "In conclusion, the observations seem to show that whilst it would be rash to form a judgment on glue from a single test, the evidences

afforded by a number may be irresistible. The experts' surest system appears to be, not to rely on single short cut tests of general quality, but to employ a number of methods, including any having especial bearing on the prospective or present uses of the glue, and then to base his conclusions on a consideration of all the results together."

The truth of the matter is that the figures have a partial value and then only to a glue expert. For instance, as a general rule hide glues have a higher viscosity and make better wood joints than bone glues; yet some bone glues, notwithstanding their lower viscosity, make magnificent joints, surpassing most hide glues. The only test that can be accepted as conclusive is a practical trial of the glue under actual working conditions, which vary in each case.

Use.—Glue is used for a multitude of purposes. Each line of work has its special requirements, and years of experience are necessary to pick out the right glue for the work. Trouble may be caused by a glue that is too strong as well as by one that is too weak. Although in using glue the most important thing is the selection of the right glue for the work, much depends upon its proper preparation and application. If anything that is glued up comes apart, the immediate verdict is "bad glue," which is often unjustifiable, for poor judgment or unskilful workmanship may be responsible.

Many users cling with blind prejudice to some brand they have confidence in, and pay, consequently, prices far above the market. This state of mind is easily understood, for they have often been deceived by unscrupulous or ignorant dealers who sell glue on its appearance only; and, furthermore, a small amount of glue may enter into the make-up of a large value of finished product, causing heavy loss if deficient. It makes no difference, *per se* whether a glue is cut in thin or thick sheets, or ground or pulverised. Nevertheless some users will pay extra prices for glues cut in special shapes.

In preparing glue for use the following points should be observed:—

1. Use definite weights of glue and water. Glue is sold by the pound and should be used by the pound. 2. Soak the glue in cold water until it has thoroughly softened. Ground glue softens more quickly than sheet or flake glue, and is therefore preferable, other things being equal. 3. Melt in a water or steam bath, and keep at as low a temperature as is consistent with the work. Prolonged heating injures glue, so that it is advisable to heat up successive small lots of the soaked up material, rather than have a large lot remain heated for a long time. 4. Make good evaporation from the glue-pot by the addition of water if necessary. 5. Use clean utensils. 6. Fit the stength of the solution to the work—don't use the glue too thick or too thin. 7. If surfaces are to be joined, have them dry and warm, if possible, and apply pressure until the glue has sufficiently "set."

Glues for particular purposes should be chosen as follows:—

Wood joints.—Most preferable are hide glues from 70 up. Lower test hide glues may give trouble. While some bone glues answer admirably, in general they should be avoided. The pieces to be joined should be thoroughly fitted, dry, and of seasoned wood.

Veneers.—Most advantageous is a bone and hide, or bone and sinew mixture, testing between grades 50 and 70. Higher test glues are apt to set too quickly. Pure hide or sinew glue is better, but more expensive, while, for cheap large surface work, bone glue may be used. If worked on a veneering machine, freedom from foam is essential.

Sizing.—As most sizing is done with special machinery, each case must be considered individually. Generally a free flowing glue, free from foam, is required. If used to surface paper, grease is undesirable, as is any marked acidity or alkalinity which might turn the shade of the colours with which the size is mixed.

Paper boxes.—For "setting up," quick setting hide glues, grades 70 to 90 are best. For "covering," lower test is necessary to prevent the glue setting too quickly; bone glues, testing grades 40 to 60, are most desirable. Of course, to the relatively higher test glues more water can be added; consequently they go further, and it is only a matter of proportion between strength and cost to determine the value.

Leather goods and belting.—Here the main points are flexibility, tenacity, and resistance to moisture. Nothing under grade 100 should be used, and higher test goods are to be recommended, because they are less sensible to moisture, and interpose less mass between the surfaces joined. Fish glue, once largely used, is in disfavour, being too hygroscopic. Most leather belt manufacturers make their own special "cement," using high grade glue or gelatine as a base, and mixing it with glycerin and other ingredients.

Bookbinding.—For rounding and backing, hide glues testing between grades 80 and 100 serve very well. If brittle low test or bone glues are used, the books are apt to crack down the back. Where simple pasting work is to be done, any sweet low-grade glue will answer.

In all cases especial machinery requires glue suited to its particular requirements.

Gelatine.—Only high testing glues, grade 100 or over, made from selected clean stock should be sold as gelatine to be used for food purposes. Nevertheless, nice looking glues of dubious origin, as long as they will pass muster, are often palmed off upon the unsuspecting purchaser. For photographic uses there are many special requirements which the gelatine must answer; and work on these, together with some investigations on the chemical nature of glues and gelatins is now being conducted in the laboratory of the National Glue and Gelatine Works, where the work described in this paper has been done.

THE CUBAN SUGAR INDUSTRY.

BY W. D. HORNE, PH.D.

The relative importance of Cuba as a sugar-producing country may be seen from the fact that of the 12,000,000 long tons of raw sugar produced annually in the world, Cuba furnishes about 1,000,000 tons. Excepting the small amount used on the island for local consumption the total product is shipped to the United States refineries.

This constitutes about 40 per cent. of the sugar consumed in this country, the total U.S. supply coming last year as follows:—

	Tons.
From Cuba	1,101,611
„ Foreign countries	438,383
„ Hawaii, Porto Rico, Philippines ..	516,098
„ domestic cane	355,402
„ „ beet	220,722
Total	2,632,216

The sugar cane was early brought to the West Indies by the Spaniards, and it soon became an important crop, flourishing phenomenally in the fertile soil and hot, damp atmosphere of these tropical islands. In Cuba the sugar crop amounts in value to some 75,000,000 dols., and constitutes by far the largest part of the total exports.

Prior to the late Cuban insurrection, in 1895, the annual crops had amounted to a million tons, but during 1896 and 1897 it dropped to a little over one-fifth of this amount, and remained at only about one-third of a million for several years, owing to the widespread devastation of canefields and destruction of factories during the period of hostilities between the Spaniards and the Cubans. But since the war the rehabilitation of the sugar industry has been continuous and rapid. Cuba is about 700 miles long by 50 miles wide on the average, and consists principally of limestone formation with some hills and mountains of older geological periods occurring at both ends and in the centre of the island. The principal cane belt is the comparatively level strip of country extending almost round the island near the coast. The sugar lands are commonly known as of the red and the black varieties. The former are derived from highly ferruginous limestone and constitute the best sugar lands in Cuba. While this soil is very sticky and heavy when wet, it is extremely pervious to water, drains well, and is easily worked when not freshly

drenched by rain. The black land occurs largely in the hilly parts, where it is underlaid by white calcareous subsoil, and in the level districts, where it is underlaid by a yellow or brown clay subsoil. The black land is heavier and more tenacious than the red, loses water very slowly, and until it is fairly well dried is difficult to work.

The rainy season extends from June to December. The manufacture of sugar is restricted to the dry season, extending from December to June, for during the wet weather the cane cannot be handled from the fields in the ox carts used.

Usually cane is planted in hills 3 ft. apart in rows 5 ft. apart. Of late the system of Dr. Zayas, in which the hills are planted 9 ft. by 12 ft. apart, has been strongly advocated as affording means of cultivating by machines drawn by animals and yielding a greater number of successive crops of richer cane. It is apt to yield less than the ordinary method during the first year, and, as yet, there have not been enough data collected to show conclusive results.

Ten successive crops can commonly be harvested in as many years from one planting, although in some cases many more can be had. The yield gradually diminishes, though the juice increases in density and in purity as the plants grow older in years. The average yield is probably 15 to 20 tons of cane per acre, though it may run up to four times this amount. When the land becomes exhausted the custom is to let it lie for some years, using it for pasture land. Only about one-fifth of the arable land is under cane cultivation, and intensive methods of agriculture are little known. Some experiments with fertilisers have been conducted with results indicating success when the price of sugar is not abnormally low. On some estates it is customary to spread the filter press cakes and the bagasse ash upon the fields, while in other places these are wasted.

In some experiments in Matanzas Province the yield of cane was increased from 28·73 tons per acre to 41·08 tons by the use of about 200 lb. sulphate of potash and 400 lb. of acid phosphate on plots of an acre, while the further addition of 2000 lb. of slaked lime to the above brought the yield up to 45·94 tons per acre.

The principal varieties of cane grown are the crystalina, blanca, and a red or purple-striped variety. Cuban cane does not suffer so much from the ravages of disease and the attacks of insect and parasitic enemies as the cane does in some other countries. But great losses of cane are sustained annually through destructive fires which often sweep through scores of acres before they can be checked. As a precautionary measure against the spread of fire, it is customary to leave lanes about 30 ft. wide unplanted between the rows at distances of about 100 yards, and broader avenues at right angles to these lanes and about twice as far apart. The latter are commonly planted in rows of plantain trees, which serve the double purpose of affording protection against the spread of fire and a very acceptable article of food in their fruit. As the cane ripens the leaves dry up and fall into a thickly-tangled and very inflammable mass which is almost impassable. A fire once started in this, whether by design or by chance spark, spreads rapidly, and in a high wind such as frequently prevails, sweeps along with fearful rapidity. Strangely enough, the cane itself survives the fire pretty well, being protected by its very tough siliceous rind and its abundant internal juice. But burnt cane must be cut, transported and crushed within four days or it will ferment. Should it be rained upon it will deteriorate sooner. Sugar made from it is usually dark and less desirable for refining. So disastrous is a cane fire apt to be that its intentional malicious setting has at times been treated as a capital offence.

In Cuba the factories usually obtain their supply of cane in part or altogether from farmers who raise it on their own land or on land belonging to the factory. These "colonos," or managers of cane colonies, contract with the factory to furnish cane to be paid for in 96° raw sugar, varying in amount from about 4 per cent. to 6½ per cent. of the weight of the cane as delivered to the mill. When cash is paid, it is still on the same basis, and the cash value of the sugar is estimated from the average daily quotations in the Havana market. Colonos operating on land owned by the factory usually have a five or ten year contract.

The cane is cut by hand with broad-bladed machettas or cutlasses, stripped of all leaves and tops, cut into pieces about 3 ft. long, and thrown into piles, whence it is picked up and carefully packed into ox carts, which transport it directly to the mill or else to the railroad, where it is loaded upon the cars either by hand or by mechanical hoists which raise the entire cartload at once.

It is well known that cane once cut will deteriorate if allowed to remain long on the ground. In order to ascertain the rate of deterioration, I made a series of analyses on cane exposed to the weather during six days. I cut 15 canes as nearly alike as possible and crushed five in a handmill at once, after having divided them into thirds of equal length, marked bottom, middle and top. The other 10 canes constituted the sample whose deterioration upon standing was to be noted. I cut one-sixth off the bottom of each, pressed them, and analysed the composite juice. Next day I took the next sixth off, and so continued for six days. There was a natural deterioration, as I took samples nearer to the top each day, but there was a further falling off in test due to deterioration of the juice itself with time, and this latter can be arrived at by comparing with the other figures as a guide.

The five canes first tested:—

	Brix.	Sucrose.	Purity.	Glucose.
Bottom third	18·85	16·95	89·90	0·37
Middle ,, ...	18·95	16·60	87·59	0·62
Top ,, ...	17·65	14·20	80·47	1·27

The 10 canes exposed to weather:—

	Brix.	Sucrose.	Purity.	Glucose.
Bottom sixth, fresh	19·10	16·97	88·85	0·62
Next sixth, 1 day old ...	18·75	16·40	87·48	0·75
,, ,, 2 days' old ..	18·70	15·93	85·20	0·93
,, ,, 3 ,, ...	18·50	15·62	84·46	0·96
,, ,, 4 ,, ...	17·85	14·35	80·42	1·29
Top ,, 5 ,, ...	17·00	11·86	69·77	2·25

A careful study of the above will show that the deterioration in purity during the first day is about 0·25 per cent.; in the next two days, about 1·75 per cent; and, in the next two days, about 4 per cent. It has been suggested that this rate of deterioration may be partly due to the relatively rapid deterioration in the freshly-exposed ends presented by each day's cutting.

The ox carts carry from about two to five tons of cane, and the railroad cars employed hold from 10 to 15 tons.

Many estates rely wholly upon the public railway service, while others supplement this with standard or narrow-gauge tracks, cars and locomotives of their own for operation within the confines of the estate.

About one-twentieth of the area of Cuba is under cane cultivation, which is said to be about one-fifth of the area on which cane could be suitably grown. The paucity of population has been the limiting factor in sugar production.

Just before the war there were about 180 factories manufacturing raw sugar, while in 1897 there were only 77 operating, the number rising last year to 177, making on the average per factory about 45,000 bags of 325 lb. of sugar each.

Many of the factories which were more or less demolished during the late war have been rebuilt, while others have remained in an abandoned condition. Meanwhile a new era has begun, with the advent of large amounts of American capital, in the building of new factories, some of which exceed any of the old ones in magnitude. But most striking of all the advances made are the improvements in scientific operation of the plants and the great attention paid to chemical control.

Cuban sugar factories are, as a rule, well equipped with modern machinery. The old muscovado sugar, boiled in open kettles and drained by long standing, is practically obsolete; while a high grade of centrifugal sugar, polarising about 95·5 to 96·0 is the almost universal product

of the factories, equipped with modern sugar machinery from France, Germany, England and the United States.

The march of improvement in sugar machinery is rapid and continuous, the efforts of the administrators of estates to perfect their plants are unflagging, and everybody on the island seems keen to learn of any advance and to apply it to his needs. The pride of excelling runs high, and on every hand one finds estates famed for and priding themselves upon some point of transcendent superiority. One claims the finest milling department, another the broadest acreage of cane, a third the most economical arrangement of working parts, while the strife to produce the greatest output in bags of sugar and the highest yield of sugar from cane are never-ending. A number of the factories are veritable show places, and not a few of the owners' residences are little short of palatial.

From the time when the cessation of the rainy season permits the cutting and hauling of cane, and the mills begin to grind, work is continuous day and night, with the exception of Sundays, until the rains come again late in the spring. The men work in alternate shifts of six hours each, the heat rendering a longer period less satisfactory.

Cane arriving at the factory by cart or railroad is unloaded upon the cane carrier either by hand or mechanically by a cane hoist lifting five or six tons at a time. Chains or wire ropes are pushed under the load of cane between transverse slats on the platform of the car or cart, the ends attached to the support above, and the load lifted bodily into the air, transported to a suitable hopper above the carrier, and there dropped by the pull of a trigger. In some cases, the cane is gradually discharged from the hopper upon the carrier by means of a revolving drum or travelling apron provided with strong hook-like teeth; in other cases, the hopper is built at the bottom of a trough 6 ft. or 7 ft. wide about half as deep, and leading up at an angle to the crusher. In the bottom of this trough is the carrier, an endless apron of wooden or metal slats or plates, or in the later models of steep ascent a link belt conveyor of great strength provided with strong steel teeth 18 in. long, curving slightly forward to elevate the heavy tangled mass of cane which falls upon it. The mass of canes in a rough layer, 12 in. or 18 in. deep, falls precipitously over the upper apex of the carrier into a hopper-like receptacle, which feeds it into the preliminary crusher, consisting of two enormously strong horizontal steel rools provided with interlocking ridges to grip, crush and tear the cane. The Krajewski crusher, with zigzag serrated corrugations, appears to give the best results. The Marshall, with alternating plain rings and rings of interlocking teeth, also gives very good results, although it appears to allow of more slipping than the other. These rolls are usually 30 in. to 34 in. in diameter and 6 ft. or 7 ft. long. They are set an inch or two apart, and can separate still farther by pushing back against very heavy spiral steel springs. The crusher is generally driven by a separate engine and exerts a tremendous pressure upon the incoming cane. Nearly half the juice of the cane is extracted here, and the cane, torn open and often cut into short lengths, passes by a travelling conveyor to the first mill proper, which consists of three rolls set closely together, the lower two in the same horizontal plane and the upper one centrally above the other two, and so placed as to leave an aperture of about 2 in. between the upper roll and the lower roll on the entering side and 1 in. between the upper roll and the lower roll where the crushed cane or bagasse passes out. Immediately beneath the upper roll, and bridging the space between the two lower rolls, is a curved plate, called the trash turner, which prevents the bagasse from passing down between the lower rolls, but feeds it across into the space between the upper and the second lower roll. One or two other similar sets of rolls follow, set with successively decreasing apertures between rolls so as to exert even greater pressure on the more and more exhausted bagasse. These mills are preferably provided with hydraulic pressure pistons, either pressing directly downward upon the upper roll or horizontally against the lower roll at the outgoing side. From 300 to 420 tons pressure or more can thus be exerted. It is usual to have the highest pressure upon the last mill and to operate this by a separate engine.

It is of great advantage to macerate the bagasse issuing from the first and second mills by sprinkling water upon it. This is very rapidly absorbed, and diluting the juice remaining in the cane, permits of a greater extraction of sugar at the next compression. The hotter the maceration water the more rapid is its diffusion, but if it is very hot it causes the roll journals to become overheated. For this reason, cool or tepid water is generally used. Some rolls are made with hollow shafts which permits of cooling by means of cold water. The amount of water of maceration added thus at the mills usually varies from 3 to 8 per cent. of the weight of the cane, being limited by the expense of its subsequent evaporation. This leaves in the bagasse about 7 to 9 per cent. of sucrose, equal to from 2 to 2¼ per cent. of sugar on the weight of cane. In Hawaii, where 20, 30 or even 40 per cent. of water of maceration is added in two or three instalments, the extraction of sugar is much more thorough, only 4·5 per cent. of sugar being left in the bagasse, equal to 1 per cent. on the weight of cane. A crusher and three triple mills will extract about 72 lb. of juice from 100 lb. of cane, when no maceration water is added, the crusher and first mill extracting 45 lb., the second mill 20 lb., and the third mill 7 lb. approximately. The juice first extracted comes from the soft interior, and has a higher density and purity than that which is extracted by the subsequent milling under higher pressure. The second and third mills extract a greater relative quantity of juice from the rind, and it has a darker colour as well as lower density and purity. The following determinations were made on juice from the different mills in different factories:

Plantation.	Crusher and first mill.			Second mill.			Third mill.		
	Brix.	Pol.	Purity.	Brix.	Pol.	Purity.	Brix.	Pol.	Purity.
1—1904	18·11	16·0	88·34	17·16	15·2	88·52	15·56	13·0	83·55
1—1905	17·63	15·64	88·76	16·95	14·66	86·51	16·40	13·7	83·56
2—1904	20·1	18·3	91·04	19·06	16·4	86·04	18·68	15·8	84·57
2—1905	19·75	16·9	85·5	19·05	16·05	84·2	18·5	15·2	82·16
3—1905	20·00	18·19	90·97	18·85	16·49	87·46	18·68	16·10	86·21
3—1905	18·70	16·76	89·60	18·55	15·99	86·21	17·25	14·68	85·09
4—1905 (no crusher)	17·4	15·51	89·13	16·6	13·88	85·97	—	—	—
5—1905 (no crusher)	19·16	17·09	89·12	18·01	15·11	83·9	17·98	14·98	83·36

The greatest economy of evaporation is reached when double or triple maceration is practised, but with only a single application of water. The water is always applied before the final crushing, but the diluted juice thus obtained may be carried back and used for macerating before the second mill. Or the thin runnings from filter presses may be used in the same way. This system has found its highest development in Egypt, where the juice is carried back twice, and where two-thirds of the extracted juice is taken from the crusher, the rest from the first mill.

When the utmost pressure is applied at the last rolls they emit a groaning or singing tone, and the bagasse, heated considerably by this enormous compression, issues like a mat of shavings and contains from 48 to 53 per cent. of moisture. It is conveyed in this condition by travelling slats through long shallow wooden troughs to the furnaces, where it is burnt upon special grates, and, under suitable conditions, constitutes the sole fuel required for the plant.

The combined juice from the crusher and all the mills flows through a finely perforated brass straining plate into a small receiving tank, and is pumped into the liming

tanks, where milk of lime is added to it immediately to neutralise acidity and to precipitate those impurities which form insoluble lime salts. Some mix powdered burnt lime with a pailful of juice and add this to the general mass, but the use of milk of lime kept constantly at 12° or 15° B. is greatly to be preferred. The amount of lime required to give the best results is an unsettled matter, some adding enough to produce a neutral or slightly alkaline reaction to litmus, others carrying it further, to alkalinity to phenolphthalein. In my experience, the lime continues to give a precipitate after mere neutrality to litmus has been reached, and to obtain a bright and clear defecated juice, it is necessary to add lime up to a point somewhere between neutrality to litmus and neutrality to phenolphthalein. In juice from cane of several years growth from lands long under cultivation and having a purity of 90, I found that lime added to cover 20 per cent. of this range was sufficient, while in a juice of 80 purity, obtained from new cane on virgin soil it was necessary to cover the full range to get the best results. I doubt whether it is ever necessary to add more lime than to reach neutrality to phenolphthalein, to effect a good clarification, while for other reasons an excess is objectionable. Liming tanks almost always serve as measuring tanks also, the juice over-flowing through an overflow pipe or marking its height by some float device. In the older establishments, it is customary to heat the limed juice in the same tanks as limed and measured in, by means of steam-jacketed bottoms or closed steam coils. In this case, a portion of the precipitate of lime salts, albuminous and pectinous matter, &c., falls to the bottom, and part rises to form a heavy blanket scum on top. The heating continues until this blanket cracks, at about 190° F., after which a period of subsidence is allowed and then the clear juice is suitably drawn off. In some of the newer plants, the Deming system of superheat defecation, so widely employed in Louisiana, is used. In this, the limed juice is heated to 130° or 140° F. under pressure, cooled again, and then passed through continuous settling tanks, of 5000 galls. capacity, having an internal conical diaphragm to direct the current of juice, and an inverted conical bottom to collect the precipitate. If the current flows slowly (5 ft. an hour), and the mud is removed from the bottom frequently (15 minutes), a pretty clear juice can be had, but it seldom is so bright as that obtained by open defecation. The slight turbidity can be removed, however, by filtration through Danek or gravity filters.

This system effects no materially better precipitation of impurities than the ordinary process, as shown by a set of experiments in which some limed juice with a purity of 83·65 showed a purity of 84·53 after being heated to boiling in an open vessel and filtering, as against 84·62 after being heated in the Deming to 240° and filtered. Prinsen-Geerligs has arrived at a similar conclusion from experiments in Java. Still, the apparatus is economical to operate and has a very great capacity. Probably better results in settling could be had if the tanks were used as intermittent instead of continuous settlers.

In all the modern factories filter presses are now used for treating precipitates and scums. This muddy mass is diluted with tank washings in special blowups, rather heavily limed and heated to near the boiling point. After settling the clear liquor is withdrawn and the muddy bottoms pumped through filter presses, having iron frames and jute or cotton cloths. It is difficult to wash the sugar out of the cake with either water or steam, and the best way to reduce the sugar is to dilute the scums sufficiently before filtering. The press cake is a good fertiliser, but in many cases it is thrown away. It contains 60 per cent. of water and from 6 to 12 per cent. of sugar.

The clarified juice is always concentrated in a multiple effect evaporator from about 9° or 10° B. up to 20° or 30° B., before being taken into the vacuum pan. The usual multiple effect for concentration *in vacuo* is a standard triple effect of one type or another. In the lower part of these upright cylindrical vessels are a large number of vertical tubes of about 1 in. diameter, and 3 ft. to 5 ft. long, their ends expanded into tube sheets. The space among the pipes and between the tube sheets constitutes the steam heating chamber, while the juice, admitted to the lower part of the effect rises through the tubes, is rapidly boiled and its vapour passes into the steam chamber of the second effect. The vapour arising from the boiling juice in the second effect is led into the steam chamber of the third effect. The vapour space of the third effect is connected with a vacuum pump maintaining in the third effect a vacuum of 26 ins. or 27 ins., as represented by the gauge. In this effect the juice is densest and the temperature of the heating steam the lowest, necessitating this high vacuum to effect evaporation. The vacuum in the second and first effects stands at about 16 and 5 respectively. The steam chamber of the first effect receives exhaust steam at a pressure of 10 or 5 lb., or less. The juice valves are carefully set, so as to allow the juice to pass gradually from one effect to another, while a pump removes the water of condensation from the steam chambers through suitable traps. Various other types of multiple effect evaporators are also in use, among them the Lillie evaporator, in which film evaporation is effected. Here the juice is evenly distributed over a great number of 3 in. horizontal pipes internally heated by steam. As the juice trickles down over these tubes in thin films evaporation is very rapid. The vapour from the juice evaporated in the first effect becomes the heating medium for the second, and so on. The juice is passed continuously from one effect to the other by means of centrifugal pumps driven by Westinghouse engines having a speed of about 300 revolutions per minute. Instead of a vacuum pump a Bulkley condenser is used working on the same principle as the Korting injector or the Sprengel air pump. The Lillie evaporator requires great care and must be reversed frequently to prevent incrustation of the tubes.

A common fault in Cuba is the failure to carry this preliminary concentration far enough. The best density to concentrate to is 30° or 32° B., anything less than this throwing unnecessary work upon the vacuum pans, which require nearly three times as much heat to evaporate a pound of water as the triple effect uses.

The usual vacuum pan in use is an iron pan of upright cylindrical shape, fitted with about six or eight copper steam coils varying from 3 ins. to 5 ins. in diameter placed one above the other in the bottom part of the pan. It is usually arranged so that the lower coils can receive live steam, and the upper coils either live or exhaust steam. Some of the newer pans are of copper, and 12 ft. or 13 ft. in diameter, while the older ones are usually smaller, 8 ft. to 10 ft. being common. Vapours from the vacuum pan are condensed in a water spray condenser, usually connected with a dry vacuum pump, and a Torricellian water column. Frequently a central condenser serves for several pans. On account of the relatively low position of the pans in most Cuban factories it is common to build the condenser high in the air, outside, with the vapour, water and vacuum pipes all leading up to it, while the barometrical water column pipe drops from it to a water overflow tank below. Water is so scarce in the island that it is usually necessary to use the condensing water over and over. This necessitates the repeated cooling of the water as it flows from the condenser, which is effected by discharging it upon the top of the cooling tower, a succession of slat floors placed one above the other at the distance of 3 ft. or 4 ft. The water is so broken into spray that evaporation cools it down to about 90° or 95° F., at which temperature it is used again.

The methods of "boiling sugar," as it is called, or extracting all the sugar possible from the juice are very numerous, for nearly every factory has its own modifications, introduced on account of the exigencies of apparatus, juice, and so forth. The most direct way, and one followed in some places, is to boil the thickened juice or "meládura" to grain in the vacuum pan, discharge the thick massecuite into iron sugar wagons holding about 20 cb. ft. each, allow it to stand about a day until it has cooled to about 105° or 110° F., and purging it in centrifugals to obtain a first or centrifugal sugar polarising about 96, and a first molasses with a purity of about 58 to 60. This first molasses is then boiled by itself to string proof, that is, until it is very thick, but

free from crystals and of such consistency that it can be pulled out into a string between the fingers. This stands about a week in wagons to crystallise as it cools, and is purged in centrifugals, yielding a second or molasses sugar and a residual molasses having a purity usually of 40 to 45. However, it is found more advantageous to begin boiling a pan of second sugar with thick juice and to build thus a grain in the pan, on which the first molasses, which is subsequently taken in, will deposit a good portion of its sugar so that one more thoroughly exhausts the molasses. This massecuite requires a shorter time, about three days, for cooling and crystallisation in the sugar wagons. Instead of starting the second sugar with thickened juice, some prefer to hold back a small part of a panful of first massecuite on which to build with first molasses, for in the massecuite the grain is already formed. Some factories, too, boil an intermediate grade of sugar by starting with about half a charge of thick juice or first massecuite, and finishing with first molasses, washing the resultant sugar with a little water in the centrifugals to raise it to 96 polarisation.

The progressive factories are provided with crystallisers for receiving the massecuite directly from the vacuum pan. Massecuite is frequently forced from pan to crystalliser through an 8 in. to 12 in. pipe by compressed air. The Westinghouse air compresser is very good for this purpose. The crystallisers are merely great tanks usually built in the shape of a horizontal cylinder 8 ft. in diameter by 20 ft. to 28 ft. long, and provided with an internal longitudinal shaft on which slowly revolves a helical stirrer which keeps the stiff mass in motion, affording better contact between the sugar crystals already formed and the molecules of sugar held dissolved in the mother liquor. This "crystallisation in motion" as it is called, is a marked advance upon the older process of allowing crystallisation to continue in wagons. Besides the better contact the cooling is more rapid, and this may be still further hastened by proper water-jacketing or by exhausting the hot vapour either with a blower or by a vacuum pump.

First magmas are purged within a day after being boiled, in some cases almost immediately, for if it is to be purged hot the magma can be boiled very dry, so as to contain only 8 per cent. of water. Second magmas usually crystallise well in three days in crystallisers, and it is possible by means of them to exhaust the molasses more thoroughly than by quiet crystallisation, as shown by the low purity of such residual molasses.

The centrifugals used for purging the sugar crystals from the mother liquor are of the Weston or of the Hepworth type, in the older factories 30 ins. in diameter, in the newer 40 ins. Most of the machines are belt driven, but the water drive is used in a few factories. The latter is more delicate in its adjustment and apparently more difficult to keep up to the desirable speed of 800 revolutions per minute, but it dispenses with much driving gear, and is very simple to operate. Some electric, directly driven centrifugals are also in use.

From the centrifugals the sugar drops through hoppers directly into bags usually holding 325 lbs., is accurately made up to this figure, and the bag sewn up, numbered, branded with the name of the estate, and shipped or stored for shipment.

Following are a few analyses of typical Cuban raw sugars:—

Grade.	Pol.	Ash.	Water.	Glucose.	Organic.
Centrifugal	97·00	0·32	1·40	0·52	0·76
"	94·30	0·63	1·01	1·74	2·32
"	94·50	0·61	1·21	1·79	1·89
"	95·10	0·67	1·37	1·15	1·71
"	94·50	0·60	1·53	1·47	1·90
"	96·10	0·57	0·73	1·36	1·24
Molasses	89·10	2·21	2·78	2·22	3·69
"	89·80	1·40	2·87	2·08	3·85

Large quantities of sugar are stored in the principal Cuban ports for shipment after the sugar crop is past, and such sugars are apt to ferment, causing a loss of several degrees in polarisation. Such a case is well illustrated in the following analyses of raw sugars received at a refinery here through the year from a single estate and all of the same polarisation (within a tenth of two) originally:—

	Jan. 1905.	Feb. 1905.	Mar. 1905.	Aug. 1905.	Dec. 1905.
Pol.	96·30	96·40	96·10	95·30	93·50
Ash	0·46	0·54	0·56	0·50	0·51
Water	1·02	1·11	1·21	1·10	1·27
Glucose	1·11	0·76	0·91	1·44	2·98
Organic	1·12	1·19	1·22	1·66	1·74

The residual molasses is often sold to local distillers for about two or three cents a gallon; a little is burned on the bagasse and more is run out into streams, or even spread upon the land. Very little is exported. Following are a few analyses:—

Samples	*a*	*b*	*c*	Analysis of ash. Per cent.	
				Fe & Al,	0·85
Pol. (direct)	35·8	28·60	31·80	Ca	9·60
" Clerget	40·85	35·40	31·96	Mg	0·56
" by inversion ...	—	35·72	—	K	28·34
" Sawyer's method	—	27·50	—	Na	2·95
				SO_4	9·86
Ash	6·96	—	15·54	Cl	10·32
Water	25·27	20·84	18·92	PO_4	6·06
Glucose	15·70	—	13·33	SiO_3	3·21
Organic	11·22	—	20·25	CO_2	24·18
				H_2O	0·79
			Undete	rmined	3·28
					100·00

A useful by-product has been developed of late in the form of a cattle food called "Molassecuite" formed by drying and shredding bagasse and then mixing it with as much thick molasses as it will hold. Such a product, upon analysis, showed the following composition:—

	Per cent.
Moisture	29·42
Fibre, crude	20·93
Sucrose	26·05
Glucose	6·06
Organic non-sugar	9·27
Ash, soluble	7·76
" insoluble	0·51
	100·00

Some efforts have been made also to utilise the fibre of bagasse for paper making, but this has not yet been adopted in Cuba.

As the idea of scientific control of the manufacturing operations gains ground in Cuba, the chemist is coming to the front, and the superintendence and management of the factory is entrusted to him rather than to the chief sugar boiler, as formerly. The modern chemical superintendent, through continuous systematic samples promptly analysed, and through constantly kept records in every department of the work, is able to see the correlation of its parts far more clearly than before.

Future advance in this great industry will depend upon the close adherence to scientific methods of investigation and control, and judging from the progress that has been made thus far, it is easy to believe that Cuba will always hold her place as one of the foremost sugar producers of the world.

Obituary.

HERMANN JOHANN PHILIPP SPRENGEL, PH.D., F.R.S.

Hermann J. P. Sprengel was born in 1834, at Schillerslage, near Hanover, and was educated in the Universities of Göttingen and Heidelberg, taking his degree of Ph.D. at the latter university in 1858. In the following year he came to England, which he thenceforth made his home. For three years he was an assistant in the chemical laboratory of Oxford University; then, coming to London, he worked in the laboratories of Guy's and St. Bartholomew's Hospitals. In 1865, he became connected with a firm of manufacturing chemists in London, but retired in 1870.

Dr. Sprengel was elected a Fellow of the Royal Society in 1878. In special recognition of his varied merits, he was created a Royal Prussian Professor (titular) by the German Emperor in his capacity of King of Prussia. His air-pump, which he described to the Chemical Society in 1865, though apparently a simple piece of apparatus, depending for its operation on the fall of mercury in narrow tubes, led to results quite disproportionate to its simplicity, and in many respects it may be said to have had an important influence on the development both of science and industry in the latter part of last century. The most important of Professor Sprengel's researches may, indeed, be said to have been concerned with the two extremes of the gaseous state of matter, namely, high vacua and explosions, though it is by his well-known mercury pump that his name will be best remembered. On the one hand, this apparatus enabled Sir William Crookes to carry out experiments leading him to his theory of radiant matter, whilst, on the other, it assisted at the birth of the incandescent lamp. Sir Joseph Swan's earliest attempts at making a carbon glow-lamp were foiled by the impossibility of getting a good enough vacuum. It was the mercury pump which enabled him to overcome this difficulty, and later on to establish the incandescent lamp as a useful commercial article.

Sprengel devoted much time to the study of a class of explosives, and, in 1871, took out patents for them; they are capable of being rapidly prepared when wanted, by mixing together two or more ingredients, which can be stored or transported without danger, because when separate, they are not explosive. One of these ingredients was a liquid, usually nitric acid, and the other picric acid or some other nitro-benzenoid dissolved in the liquid. Or, porous cakes of potassium chlorate were drenched with a liquid such as carbon bisulphide or nitrobenzene. Doubtless the employment of a mixture of ammonium nitrate and nitrobenzene for blasting powders, &c., followed as a consequence of Sprengel's researches. He was the first to call attention to the value of picric acid as an explosive, when fired by a detonator, and it may be said with truth that the employment of this class of substance, generally, owes its origin to his experiments and observations.

He died suddenly on Sunday, January 21st.

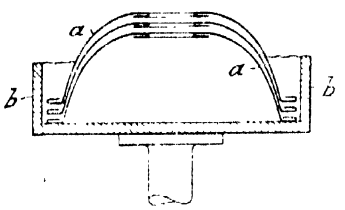
ENGLISH PATENTS.

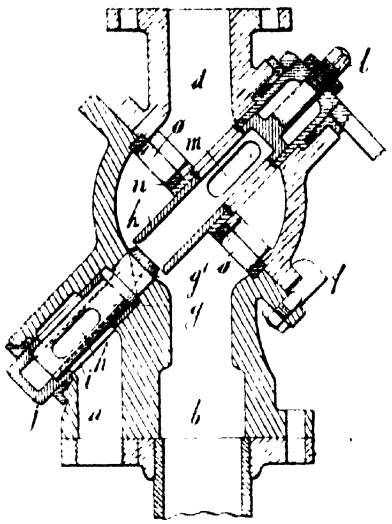


Drying Machines; Cylinder ——. J. R. Hatmaker, Paris. Eng. Pat. 1177, Jan. 21, 1905.

THE invention relates to a drying cylinder heated by means of gas jets disposed inside it. The claim is for the interposition of a layer of sand or other heat-resisting and distributing material between the flames of the gas jets and the inner side of the drying surface. The material is contained in an annular space between the cylinder wall and an inner concentric lining wall. In this way local overheating of the surface of the cylinder is stated to be avoided. (Reference is directed to Eng. Pat. 2273 of 1901.)—W. H. C.

Air Drying Apparatus; Improved ——. E. W. Cooke, and J. F. Kelly, New York. Eng. Pat. 14,856, July 19, 1905.

A NUMBER of vertical cells, fitted with a moisture-absorbing material such as calcium chloride, are arranged round a vertical shaft in a casing. The latter is provided with partitions so arranged that while a current of air is being dried by passing through one of the cells, the others are being regenerated. This is effected by passing a current of heated products of combustion from an oil burner through the cells. The shaft is rotated so that the cells are alternately drying air and being themselves dried. The air to be dried is warmed, before reaching the drying cells, by being passed through a chamber at the top of the casing which is heated by the waste gases after they have passed through the cells that are being dried.—W.H.C.



Separators; Impts. in centrifugal ——. A. F. Spooner, London. From Aktiebolaget Separator. Stockholm. Eng. Pat. 1606, Jan. 26, 1905.

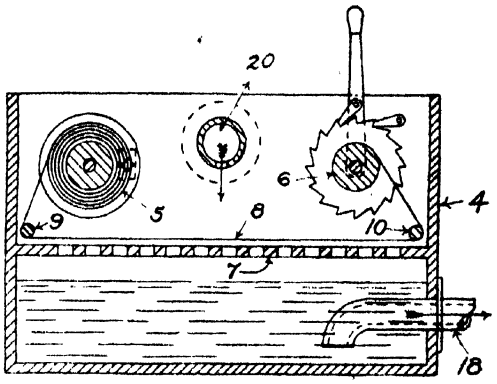
THE claim is for forming a liner for the bowl *b*, of a centrifugal separator, of a number of superposed domed plates *a*, of the shape shown in the figure.—W. H. C.

Heating of Water or other liquids; Apparatus for the ——. C. Barter, Birmingham. Eng. Pat. 8340, April 19, 1905.

STEAM entering by the tube *a*, and passing through the openings *i*, *h*, issues from the jet *g*, and enters the tube *k*, drawing with it some water through the annular space g^1, from the tube *b*. The water is heated and passes through *m*, into the delivery pipe *d*. The latter is connected to the supply pipe *b*, by a planed joint, inclined at an angle of 45°, and secured by hook-bolts *f*. By rotating the faces of the joint the pipe *d*, may either form a prolongation of the pipe *b*, or may be set at an angle to it. The valves *g*, and *k*, can be regulated by turning the nuts *j*, and *l*, and a disc-valve *n*, provided with orifices *o*, which can be opened

or closed by rotating the disc, allows the cold water to continue to flow when the steam is shut off.—W. H. C.

Mixing or combining liquids or fluids; Method of mechanically —— and Apparatus therefor. F. J. H. M. Berberich, Kiel, and W. G. Schröder, Lübeck, Germany. Eng. Pat. 8895, April 27, 1905.



After a preliminary mixing in a vessel provided with an agitator, the mixed fluids are forced through a tube in which is placed a cylinder of less diameter than the tube, and whose surface is covered with angular projections. These projections are preferably formed by the intersection of right- and left-handed screw-threads cut upon the cylinder. The fluids are then forced through another tube in which there is a cylindrical plug with a conical end, which has a screw-thread cut upon it. The passage of the fluid through this tube causes the plug to rotate, and the fluids are ground or pulverised between the plug and tube, and thoroughly mixed together.—W. H. C.

Compressing air or gases; Method of ——. F. Windhausen, jun., Berlin. Eng. Pat. 11,140, May 27, 1905. Under Int. Conv., May 28, 1904.

One or more turbine compressors are used to effect the first or low-pressure stage of compression, and reciprocating compressors are used to complete the compression in the high-pressure stage. By this combination it is stated that the inconvenience due to the necessity of using cylinders of large dimensions when reciprocating compressors are used for the low-pressure stage and to the low efficiency of turbine compressors for the higher stages is avoided.—W. H. C.

Filters for purifying fluids, especially for extracting the oil and other impurities from condensation water, emanating from steam-engine exhausts. J. S. Milne, Camden, N.J., U.S.A. Eng. Pat. 12,716, June 20, 1905.

The filter cloth, wound upon the spool 5, passes over the roller 9, across the perforated plate 7, and round the roller 10, and is then wound on to the spool 6. The liquid to be filtered enters at 20, passes through the filter-cloth 8, and the perforated plate 7, and is drawn off through 18. The filter-cloth is drawn across the plate by turning the spool 6, at such a speed that fresh portions of the cloth come into use as the previous parts become covered with deposit. When the whole roll has been used, the spools are removed bodily from the filter-tank

and washed. (Reference is directed to Eng. Pat. 13,612 of 1894; this J., 1895, 736.)—W. H. C.

Acid-Proof Vessel for distilling and other purposes. G. W. Liddiard, Manchester. Eng. Pat. 14,092, July 8, 1905.

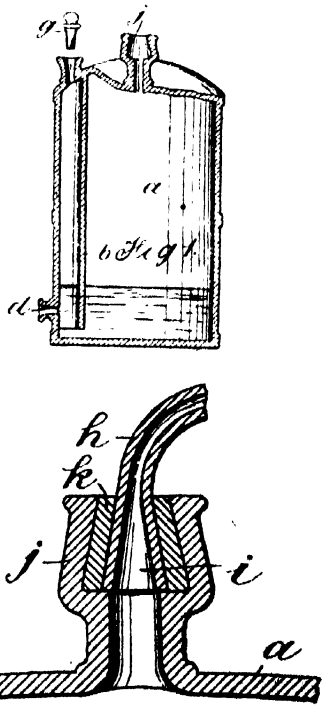


Fig. 2.

The improved construction consists in forming a partition *b*, within the vessel *a*, which is made of porcelain or other acid-proof material. The partition extends to below the level of the draw-off plug *d*, forming a liquid seal so that when the test plug *g*, is withdrawn, only a small amount of gas or vapour can escape. Further claim is made for an improved joint shown in Fig. 2; the end of the connecting pipe *h*, is opened out into a cone *i*, and is inserted into a conical cavity *j*, formed in the neck of the vessel. Packing material *k*, is then inserted between *i*, and *j*, and the greater the pressure in the vessel the tighter the joint is stated to become.—W. H. C.

Obituary.

HERMANN JOHANN PHILIPP SPRENGEL, PH.D., F.R.S.

Hermann J. P. Sprengel was born in 1834, at Schillerslage, near Hanover, and was educated in the Universities of Göttingen and Heidelberg, taking his degree of Ph.D. at the latter university in 1858. In the following year he came to England, which he thenceforth made his home. For three years he was an assistant in the chemical laboratory of Oxford University; then, coming to London, he worked in the laboratories of Guy's and St. Bartholomew's Hospitals. In 1865, he became connected with a firm of manufacturing chemists in London, but retired in 1870.

Dr. Sprengel was elected a Fellow of the Royal Society in 1878. In special recognition of his varied merits, he was created a Royal Prussian Professor (titular) by the German Emperor in his capacity of King of Prussia. His air-pump, which he described to the Chemical Society in 1865, though apparently a simple piece of apparatus, depending for its operation on the fall of mercury in narrow tubes, led to results quite disproportionate to its simplicity, and in many respects it may be said to have had an important influence on the development both of science and industry in the latter part of last century. The most important of Professor Sprengel's researches may, indeed, be said to have been concerned with the two extremes of the gaseous state of matter, namely, high vacua and explosions, though it is by his well-known mercury pump that his name will be best remembered. On the one hand, this apparatus enabled Sir William Crookes to carry out experiments leading him to his theory of radiant matter, whilst, on the other, it assisted at the birth of the incandescent lamp. Sir Joseph Swan's earliest attempts at making a carbon glow-lamp were foiled by the impossibility of getting a good enough vacuum. It was the mercury pump which enabled him to overcome this difficulty, and later on to establish the incandescent lamp as a useful commercial article.

Sprengel devoted much time to the study of a class of explosives, and, in 1871, took out patents for them; they are capable of being rapidly prepared when wanted, by mixing together two or more ingredients, which can be stored or transported without danger, because when separate, they are not explosive. One of these ingredients was a liquid, usually nitric acid, and the other picric acid or some other nitro-benzenoid dissolved in the liquid. ENGLISH PATENTS.

Drying Machines; Cylinder ——. J. R. Hatmaker, Paris. Eng. Pat. 1177, Jan. 21, 1905.

THE invention relates to a drying cylinder heated by means of gas jets disposed inside it. The claim is for the interposition of a layer of sand or other heat-resisting and distributing material between the flames of the gas jets and the inner side of the drying surface. The material is contained in an annular space between the cylinder wall and an inner concentric lining wall. In this way local overheating of the surface of the cylinder is stated to be avoided. (Reference is directed to Eng. Pat. 2273 of 1901.)—W. H. C.

Air Drying Apparatus; Improved ——. E. W. Cooke, and J. F. Kelly, New York. Eng. Pat. 14,856, July 19, 1905.

A NUMBER of vertical cells, fitted with a moisture-absorbing material such as calcium chloride, are arranged round a vertical shaft in a casing. The latter is provided with partitions so arranged that while a current of air is being dried by passing through one of the cells, the others are being regenerated. This is effected by passing a current of heated products of combustion from an oil burner through the cells. The shaft is rotated so that the cells are alternately drying air and being themselves dried. The air to be dried is warmed, before reaching the drying cells, by being passed through a chamber at the top of the casing which is heated by the waste gases after they have passed through the cells that are being dried.—W.H.C.

Separators; Impts. in centrifugal ——. A. F. Spooner, London. From Aktiebolaget Separator. Stockholm. Eng. Pat. 1606, Jan. 26, 1905.

THE claim is for forming a liner for the bowl *b*, of a centrifugal separator, of a number of superposed domed plates *a*, of the shape shown in the figure.—W. H. C.

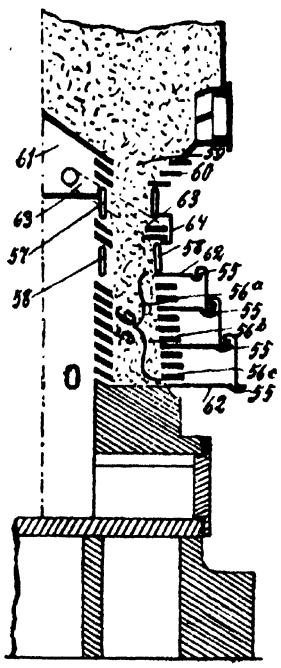
Heating of Water or other liquids; Apparatus for the ——. C. Barter, Birmingham. Eng. Pat. 8340, April 19, 1905.

STEAM entering by the tube *a*, and passing through the openings *i*, *h*, issues from the jet *g*, and enters the tube *k*, drawing with it some water through the annular space g^1, from the tube *b*. The water is heated and passes through *m*, into the delivery pipe *d*. The latter is connected to the supply pipe *b*, by a planed joint, inclined at an angle of 45°, and secured by hook-bolts *f*. By rotating the faces of the joint the pipe *d*, may either form a prolongation of the pipe *b*, or may be set at an angle to it. The valves *g*, and *k*, can be regulated by turning the nuts *j*, and *l*, and a disc-valve *n*, provided with orifices *o*, which can be opened

THE general construction of the producer is shown in Fig. 1; its essential characteristic is the arrangement of the two grates 50, and 52. The outer grate 50, is composed of a number of bars, laid in a frame, like the laths of a Venetian blind. The inner grate consists of a flat tube, which is filled with water, and coiled in a helix, loosely enough to allow air, &c., to pass through into a gas-collecting chamber 53, but overlapping to prevent the passage of coal. Air is supplied to the centre of the apparatus, spreads under the gasification chamber, or the space between the grates, and enters the same through the spaces between the bars. The lower portion of the outer grate, 51, is hinged to allow the removal of ash, &c. The grates may be curved at their upper or lower ends, or both, so as to leave wider spaces between them at the top and bottom, in order that the gasification process may be most active in the narrowest (central) portion; and as the lower portion contains a large amount of de-gasified fuel, less air is supplied to it.

To regulate the supply of air to the grate, and to vary

Fig. 2.



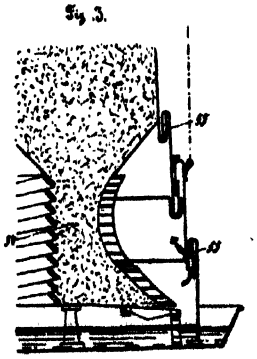


Fig. 3.

the amount of grate space required, according to the variations in the demand for gas, a series of rims or bells are arranged round the outer grate, and can be raised to allow air to pass to other portions of the grate, if more gas is required, or lowered to cut off those portions, if less gas is required. Projecting shelves are attached at intervals to the outer grate, and have at their outer extremities cups or troughs 55, into which the curved edges of the bells fit; the method of working is shown in Fig. 3.

The arrangement for decomposing the tar produced in the gasification of bituminous fuel is explained by reference to Fig. 2. The hearth is divided into (*a*) a low burning fire zone 60, (*b*) a clearing zone 59, and (*c*) a gasifying zone 56, the latter being divided into other zones provided with shutters and rims. The zones 56, 59, and 60, are separated from one another by a transverse wall 57, and by "interruptions" 58, in the grates. The tar-laden gases collect in the chamber 61, and pass by a conduit 63, to the chamber 64, which surrounds the outer grate of the zone 59, or "glowing" zone, where the tar is decomposed. The zone 56, is sub-divided by the transverse plates 62, and the shutters 55, which are regulated to meet the demand for gas. To work the producer as a pressure apparatus, the outer grate of the zone 60, must be surrounded by a chamber similar to chamber 64, and air under pressure introduced into the chambers of the zones 60, and 56^c, 56^b, and 56^c.

The whole apparatus is thus arranged to supply a gas practically free from tar, and to regulate the supply according to the demand.—W. C. H.

Lime Burning and the recovery of power-gas as a bye-product; Impts. in and apparatus for ——. The Chalk Power Gas Synd., Ltd., and H. S. Stoneham. Eng. Pat. 2684, Feb. 9, 1905. IX., page 182.

Gas maker for heavy oils. A. Eveno, Paris. Eng. Pat. 3408, Feb. 18, 1905.

GAS for use in internal combustion motors is made from heavy oils by gasifying these in a retort of graphitic iron coated with plumbago. The presence of the free carbon favours the decomposition of the heavy oils. The retort is surrounded by a jacket in which the exhaust gases of the engine circulate. To increase the surface and duration of the contact of the products of distillation and the oxygen or air used for gasification, the mixture descends through a channel to the base of the retort and then rises, circulating between the coils of a helix formed round this central passage in the retort, before passing into the carburettor. —R. L.

Gas for power purposes; Process for preparing compressed ——. O. Assmann, Tegelen, Holland. Eng. Pat. 11,413, May 31, 1905. Under Int. Conv., June 1, 1904.

SEE Fr. Pat. 354,837 of 1905; this J., 1905, 1103.—T. F. B

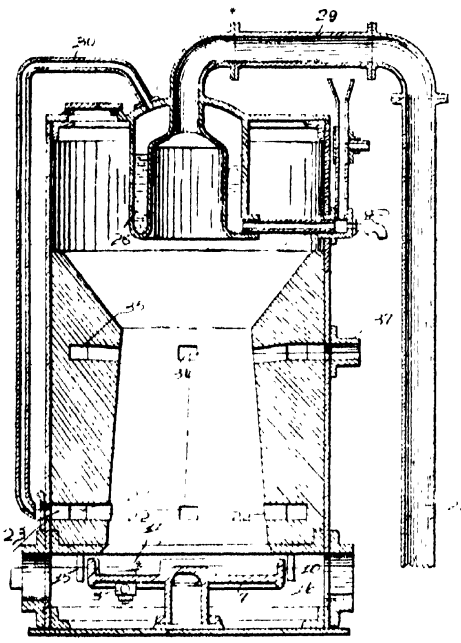
Gas Purifiers; Impts. in ——. S. Cutler, London. Eng. Pat. 7324, April 6, 1905.

IN gas purifiers fitted with "Jager" grids, the gases pass horizontally through the purifying mass. To maintain a uniform density throughout the mass of the purifying material, the bars or slabs of a similar net-like grating are now fitted in rectangular frames, and arranged in the purifier casing in superimposed horizontal layers in such a manner that the individual bars form obliquely ascending rows, the gas passing in this direction through the material. Distributing and collecting chambers are provided beneath and above the mass, and the bottom layer is placed on a tier of horizontal grids or sieves in the usual manner.—R. L.

Gas; Burner for testing ——. C. C. Carpenter. Eng. Pat. 24,828, Nov. 30, 1905. XXIII., page 199.

UNITED STATES PATENTS.

Fuel; Manufacture of artificial ——. A. Stillesen, New York. U.S. Pat. 809,998, Jan. 16, 1906.



APPROXIMATELY 75 parts by weight of petroleum, 16 of turpentine and 2 of sodium palmitate or stearate, are mixed together and heated, with agitation, along with 5 parts of caustic soda and 2 of water.—C. S.

Gas mixtures; Producing combustible ——. C. K. Harding, Chicago, Ill. U.S. Pat. 803,534, Oct. 31, 1905.

PETROLEUM or kerosene of high flashing-point is vaporised in a suitably constructed lamp by passing a current of air over a wick impregnated with the oil; the mixture is submitted to the action of a catalytic substance such as platinised tripoli, placed in proximity to the vaporising surface of the wick. By the catalytic action, partial combustion takes place and the gases formed are burned in connection with an incandescent mantle. A shield localises the heat of the catalytic surface to a portion of the vaporising surface; its initial heating is effected by a flame from a small auxiliary wick.—R. L.

Gas-Producer. E. Krenz, St. Louis, Mo. U.S. Pat. 804,814, Nov. 14, 1905.

A WATER heating vessel 28, is arranged in the upper part of a suction gas-producer, and the steam generated by the heat given off during the preliminary carbonisation of the fuel, is conducted by the pipe 30, to the air inlet 23, where it is injected into the annular air and steam distributing chamber 21, 22. The generator is charged with bituminous coal, which is partially burnt and coked in the upper part of the chamber, the smoke produced passing away by the flue 29. In the lower part of the chamber, the incandescent coked fuel is decomposed by the steam and air into fuel gas, which is drawn off through openings 36, the annular chamber 35, and the pipe 37. By adjusting the suction on the pipes 29, and 37, the smoke and fuel gases are kept apart. The ashes collect on the saucer-shaped bottom piece 7, which can be turned horizontally by the handle 8 to allow the openings 10, and 11, in the upturned edge to come into line with corresponding openings 15, 16, in the projecting flange, so that the ashes can be raked out. These openings also serve for the admission of air during the preliminary heating of the producer.—W. H. C.

Gas Apparatus; Power ——. G. M. S. Tait, Montclair, N.J., Assignor to Combustion Utilities Co., New York. U.S. Pat. 810,685, Jan. 23, 1906.

THE gas is drawn from a suction-producer through a scrubber and gas-purifier by a blower or fan, and is delivered to an internal explosion engine. The fan or blower has a liquid-seal by-pass so that the gas can be delivered to the engine under a constant predetermined pressure.—W. H. C.

Calcium Carbide; Apparatus [Electric Furnace] for the production of ——. E. F. Price, G. E. Cox and J. G. Marshall, Asignors to Union Carbide Co., U.S. Pat. 809,842, Jan. 9, 1906. XI*A*., page 180.

FRENCH PATENTS.

Drying-oven with superposed floors for drying coal or the like. P. Ostertag. Fr. Pat. 358,035. Sept. 26. 1905.

THE oven is specially intended for drying bodies such as coal which can be submitted to a high temperature when wet, but which take fire easily if exposed to a high temperature when nearly dry, and which must therefore be dried by exposing them to successively lower temperatures. The coal to be dried is fed from a hopper on to the topmost of a series of superposed inclined drying floors arranged in an oven. The coal is moved over the floor by an agitator, and is dropped through a trap on to the floor next below, being finally delivered to a conveyor. The hot products of combustion from a furnace situated in the same building, but separated from the drying floors by a hollow bridge-wall, are led either directly to the top floor or through the hollow bridge to the other floors, over the coal and away to a chimney carrying the vapour with them from each floor separately. By means of dampers a regulated amount of air is admitted with the gases to each of the lower floors, so that the temperature in each is kept at the desired degree.—W. H. C.

Combustible or artificial coal composed of house refuse and nightsoil, ground together with coal or charcoal dust and an agglomerant composed of water, molasses and glucose. J. P. Reneaux, and A. Perrier. Fr. Pat. 358,200, Oct. 2, 1905.

ABOUT 25 parts of coal or charcoal dust are thoroughly ground and mixed with about 75 parts of house refuse and nightsoil, and the resulting mass is mixed with a boiling solution composed of about 85 parts of water, 10 parts of molasses and 5 parts of glucose. When the mixture has attained a sufficient degree of consistence it is briquetted.—W. H. C.

Gas Generator and appliances. J. J. Deschamps. Fr. Pat. 357,953, June 5, 1905. Under Int. Conv., June 7. 1904.

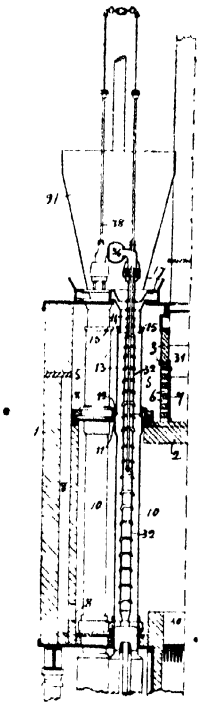
THE inventor claims, in gas generators, the practice of making the body of metal unlined with refractory material, and cooling it by means of gills and an external water jacket; also, in suction-gas plant, surrounding the ash-box and part of the body by a casing open at the top only, to produce a down-draught, and heat the air by contact with the walls and charge it with vapour; the provision of means for admitting this air above and below the fire-bars; the provision of a regulator, consisting of a closed vessel, in the gas pipe, which vessel contains a liquid the expansion of which (when the gas temperature becomes unduly high) causes a piston to open a water tap supplying a tank communicating with a water-seal round the base of the generator body, thus causing the water to overflow and trickle down into the ash-box, where it is vaporised and reduces the temperature of the fuel in the generator; the application of the same principle to regulate the supply of cooling water to the motor; the provision of a refractory covering for the mouth of the gas pipe, and the arrangement of the upper part of the same to facilitate charging the generator; the provision, in the attached scrubber, of a water jacket for cooling the lower portion of the gas pipe, and the provision of a needle-valve in the gas pipe, to regulate the pressure in intermittent suction plants.—C. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 117.)

Paraffin Wax; Cause of the transparency of ——. L. Neustadtl. Chem.-Zeit., 1906, **30**, 61—62.

TRANSPARENT paraffin wax fetches a better price in the market than "milky" paraffin wax, but hitherto the cause of the milkiness has not been studied. The author shows that it depends upon the melting points of the different constituents of the wax. When these lie within fairly close limits the product is invariably transparent, the reverse being the case when the different paraffins present differ widely as regards their melting points. Products intermediate between these varieties are transparent, but contain numerous milky particles. The cause of this appears to be due to the subsequent separation of paraffins of lower melting point after those of higher melting point have solidified. It is possible to prevent this subsequent crystallisation, and thus to render a "milky" wax transparent, by rapidly cooling when near its melting point. But this can only be done in very thin layers of 2 to 5 mm. in thickness. For the further investigation of the differences between the different kinds of paraffin wax the author has determined the speed at which they cool in a vacuum-jacketed tube, the temperature readings being taken at intervals of one minute from 60° C. downwards. It was found that when curves were plotted in which the abscissæ represented the time, and the ordinates the corresponding temperatures, there was a marked difference in the behaviour of the three kinds, *viz.*, milky paraffin wax of m. pt. 52·6° C., spotted wax of m. pt. 54·2° C., and transparent wax of m. pt. 55·2° C. Above the melting point the curves fell very rapidly, then ran nearly horizontal for some minutes near the melting points, and then slowly fell, forming very different arcs between the points of 50° and 40° C. The "milky" paraffin wax required 58 minutes to cool to the lower temperature, as against 7 minutes for the "spotted" paraffin wax and 22 minutes for the transparent wax.—C. A. M.



ENGLISH PATENTS.

Distillation of Coal and other substances; Destructive ——. J. Bowing, Tilbury, Essex. Eng. Pat. 580, Jan. 11, 1905.

THE destructive distillation of coal and other substances is effected by the action of superheated steam passed through chambers or passages in the walls of the retort. A practically uniform temperature of about 650° C. is maintained over the whole area of the retort.—R. L.

Charcoal; Kilns for making or revivifying animal or other ——, *or for carbonising other substances.* J. Buchanan, Liverpool. Eng. Pat. 4925, March 9, 1905.

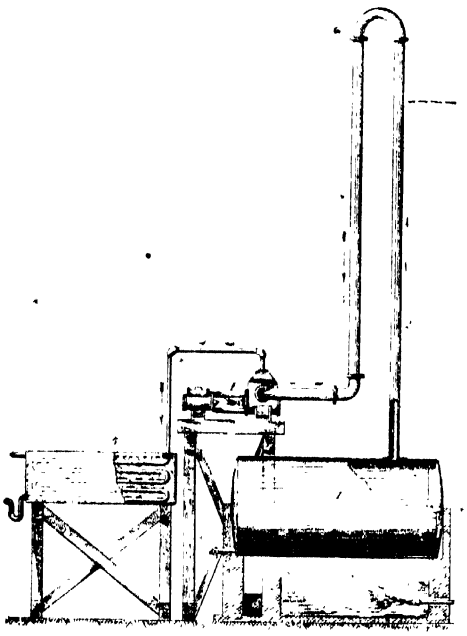
THE drawing is a vertical section of part of the kiln, the walls 1, being made considerably higher than has been the practice hitherto. A horizontal division wall 2, is arranged about one-third of the depth from the top, through which the kiln pipes 10, pass. 3, is a wall with openings 6, and dampers 7, between the division wall and the top plate. The kiln pipes are of the usual construction and operation, the upper ends passing through openings 11, in the division wall and sockets 12, in which rest drying pipes 13, provided with feeding funnels 14, fitted into the pipes by sliding ring joints 15, to allow of expansion, contraction, and lateral motion, while preventing entrance of air. 18, is a false top plate with openings above each drying pipe, and 21, is a large hopper resting on the top plate, from which, as the charcoal passes down the kiln pipes, fresh supplies are continually fed through the funnels into the drying pipes. The products of combustion from the furnace 30, circulate through the kiln pipes, then through openings and flues 8, into the chamber 5, and finally through the drying pipes. They then escape through the openings and flue 31, to the chimney. 32, are perforated outlet pipes for the escape of steam and gases liberated from the charcoal. The upper ends are formed with annular channels for containing water, into which dip pipes attached to a box 34, so that water seals are formed, thus preventing leakage of steam into the hopper. The

dip-pipes are provided with hoods to prevent any of the charcoal in the hopper entering the water-seals or outlet pipes. 38, are small pipes arranged within the outlet pipes connected to an external compressed-air supply, and having deflecting cups, perforations or branches for directing air against or among the charcoal passing down the kiln pipes, whilst for regulating the quantity and position of the air supply, valves, sliding pistons and other controlling devices are used.—D. B.

Benzene; Manufacture of non-inflammable products from ——. H. Birkbeck, London. From E. B. Barboni, Paris. Eng. Pat. 1202, Jan. 21, 1905.

SEE Fr. Pat. 350,312 of 1904; this J., 1906, 117.—T.F.B.

UNITED STATES PATENTS.



Resinous Woods; Apparatus for obtaining the products of ——, *by dry Distillation.* J. Friis, Gamla, Russia. U.S. Pat. 805,848, Nov. 28, 1905.

THE apparatus comprises an oblong oven made of boiler-plate, dished at the bottom, and rounded at the ends. It is supported on a brick foundation surrounded by inclosing walls with furnaces at opposite ends and chimneys midway in the length of the complete apparatus. The space between the oven and the walls contains a series of inclined partitions and the oven is provided with transverse pipes, so arranged that the hot gases from the furnaces are made to follow circuitous paths to ensure the thorough heating of the interior of the oven as well as the exterior. The gaseous products of distillation pass progressively through a series of condensers immersed in water vessels connected with each other, where they are gradually condensed, the final condensation being effected in a coil condenser at the end of the series.—D. B.

Wood-Distilling; Retort for ——. J. T. Denny, Cromartie, North Carolina. U.S. Pat. 806,877, Dec. 12, 1905.

The retort comprises a heavy iron or steel shell closed at the top by a cover provided with a ring bolt, by which it may be lifted. To protect the shell from the high heat necessary to char the wood, and thereby increase its life, it is incased in asbestos "lagging," held in position by segments, preferably of cast iron, provided with lugs and bolts. The retort is enclosed by brickwork, which extends nearly to the top and is spaced from the shell to form an annular heating chamber, in which are disposed two baffles, arranged diametrically opposite each other to deflect the currents of heated air. The bottom of the retort is provided with a double floor, the upper one being conical and the lower one flat, "lagging" being disposed between the floors. The shell extends below the double bottom and contains suitable inlet and outlet passages, so that the products of combustion pass beneath the bottom of the retort, and then in an upward direction to the annular heating chamber; after circulating round one-half of the retort, they pass over the baffles and finally escape through a flue to the chimney.—D. B.

Distillation [of 'Crude Petroleum']; Process of ——. G. H. Bradford, Stockton, Cal., Assignor to J. Treadwell, San Francisco. U.S. Pat. 805,116, Nov. 21, 1905.

The vapours leave the still 1, by the vertical pipe 2, which is carried upwards to a greater height than that to which the liquid in the still can rise in a vacuum. The vapour pipe then returns downwards 3, and is connected to a vacuum pump 4, which delivers the vapours to a condenser 5. It is stated that owing to the height of the pipe 2, no liquid can pass over from the still to the condenser along with the vapour, and that consequently the distillates obtained are much purer than with an ordinary vacuum still.—W. H. C.

Benzine and the like; Apparatus for continuously distilling ——. A. H. L. Gerhardt, Bettenhausen, Germany. U.S. Pat. 810,637, Jan. 23, 1906.

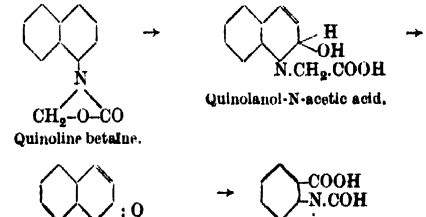
See Fr. Pat. 335,034 of 1903; this J., 1904, 111.—T. F. B

Fibres; Solvent to be used in effecting the incipient subdivision and decomposition of the semi-liquid cambium layer and epidermis of Bast ——. [*Utilisation of waste from petroleum refining.*] M. H. Colahan. U.S. Pat. 806,954, Dec. 12, 1905. V., page 177.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 118.)

Amines; Action of Formaldehyde and Alkali Bisulphites on primary —— and synthesis of Indigo. R. Lepetit. Bull. Soc. Ind. Mulhouse, 1905, 75, 379—384.



Anilinemethylene-exo-sulphonic acid, $C_6H_5.NH.CH_2SO_3H$, formed by the action of sodium bisulphite (5—6 litres of a solution at 36° B.) and formaldehyde (1300 grms. of a 40 per cent. solution) on aniline (1000 grms.), is a crystalline compound which is sparingly soluble in cold water and in alcohol. It dissolves, with partial decomposition, in alkali solutions. When heated with acids, it is decomposed, giving an orange-coloured solution. It combines with diazo salts, yielding compounds which, on heating with alkalis, are decomposed with liberation of formaldehyde and sulphurous acid. When acidified, compounds appear to give products containing free amino-groups, which can be diazotised and combined with dyestuff components, giving rise to a series of new dyestuffs.

Methylene-exo-sulphonic acids, similar to the compound derived from aniline, are obtained by the joint action of bisulphites and formaldehyde upon other primary arylamines, *e.g.*, *o*-toluidine, phenetidine, anthranilic acid, &c. In aqueous solutions of potassium cyanide they dissolve, giving, when heated, oils, or when the action occurs at the ordinary temperature, crystalline deposits, of nitrile compounds of the general formula, $R.NH.CH_2.CN$. These are insoluble in water, but dissolve readily in alcohol, from which they are precipitated by water in brilliant crystalline plates. The compound obtained from aniline, namely, phenylacetonitrile, when fused with caustic soda, yields ammonia and indoxyl, phenylglycine apparently being formed as the first phase of the reaction, and becoming transformed into indoxyl, as observed by Biedermann and the author (this J., 1891, 41) On pouring the melt into water and exposing the solution to the air, indigo is produced.

G. Freyss points out that the Badische Co. in a patent (Ger. Pat. 132,621 of July 13, 1901), taken out after the date (March 6, 1900; sealed note, 1170) of Lepetit's paper, refer to the product of the action of sodium bisulphite and formaldehyde on aniline as anhydroformaldehyde-aniline bisulphite. Further, Freyss finds that the m.pt. of the crude phenylacetonitrile obtained as described is 40—43° C., whilst that of the pure compound is stated by A. Braun to be 47—48° C. The nitrile dissolves gradually in a dilute solution of caustic soda with the formation of ammonia.—E. B.

Indigo from Quinoline; Formation of ——. H. Decker and C. Kopp. Ber., 1906, **39**, 72.

The addition product of chloroacetic ester with quinoline is oxidised with a hot solution of permanganate. The filtrate is made alkaline, evaporated to dryness, and heated to 200° C. The melt is then treated precisely as the phenylglycinecarboxylic acid melt in the technical preparation of artificial indigo. The mechanism of the reaction is explained by the following formulæ:—

Quinoline betaine. Quinolanol-N-acetic acid. Quinolone-N-acetic acid. Formyl-phenyl-glycin-o-carboxylic acid.

—H. L.

Lakes from aniline and its homologues; Black ——. S. Kirpitschnikoff. Z. Farben-Ind., 1906, **5**, 41—44.

The author has studied the oxidation products of aniline, *o*- *m*- and *p*-toluidine, cumidine and xylidine. The aniline lake was prepared from a mixture of 7·2 parts of sodium chlorate solution (1 in 2), 35 parts of potassium ferrocyanide solution at 12° B., 12 parts of water, and 26 parts of a mixture of aniline hydrochloride, 20 parts and water 53 parts. The other amino lakes were prepared from mixtures consisting of 52 parts of sodium chlorate solution (1 in 2), 25·5 parts of potassium ferrocyanide solution at 12° B., 8·5 parts of water, and 22 parts of a mixture of amino compound, 4 parts, hydrochloric acid at 15·5° B. 4 parts, and water, 14 parts. After adding 10—20 parts of hydrochloric acid at 15·5° B. to each of the mixtures, they were heated gradually to the following temperatures:—For aniline black, 60° C.; *o*-toluidine black, 75° C.; *m*-toluidine black, 60° C.; *p*-toluidine black, 60° C.; cumidine black, 80° C.; and xylidine black, 66° C. The different mixtures were then allowed to stand for 1—2 days, filtered, and the precipitates washed with cold dilute hydrochloric acid. The lakes from aniline and xylidine gave green, toluidine blackish-brown and cumidine greenish-yellow solutions. On extracting the precipitates with alcohol and ether, and boiling the extracts with water, a soluble product and an insoluble residue was obtained. For the preparation of pure lakes, as hydrochlorides or bases, it is necessary to boil the precipitates repeatedly and for some time with hydrochloric acid to remove ferric oxide, which is not easily separated and mars the colour effects, as will be seen from the following table:—

Lakes with Admixtures of Iron.

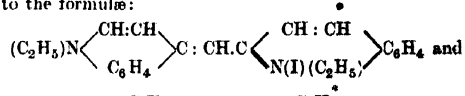
	Salts.	Bases.
Aniline black	Dark blue (hard lumps)	Dark violet
o-Toluidine black	Dark blue (fine powder)	Black with brown tinge
m-Toluidine black	Dark blue (hard lumps)	Black
p-Toluidine black	Light blue	Brownish-black
Xylidine black	Dark blue	Dark brown
Cumidine black	Dark blue	Dark brown

Lakes without Iron.

Aniline black	Dark blue, almost black powder	Dark green (powder)
o-Toluidine black	Light blue	Dark brown (fine powder)
m-Toluidine black	Dark blue	Black powder
p-Toluidine black	Blue, fine powder	Dark brown
Xylidine black	Greenish-brown	Dark brown powder
Cumidine black	Dark blue powder	Black, turning brown on grinding

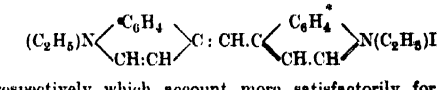
The greatest difference in colour is that exhibited by aniline black, the red of the ferric oxide masking the green of the pure base, a circumstance, which accounts for the growing use of ferrocyanides in aniline black dyeing.—D. B

Diamines; Diazo derivatives of the aromatic ——. L. Vignon. Comptes rend., 1906, **142**, 159—161.



The diazotisation of the two amino groups of the diamines only resembles that of the monamines when the amino groups are joined to two different benzene nuclei, as in benzidine. When both amino groups are joined to the same nucleus, no diazo derivative is obtained in the case of the orthodiamines, whilst in the case of the meta- and para-diamines, the diazo derivatives are very unstable and are not available for making diazoamino compounds. Attempts to obtain diazoamino compounds by the combination of two molecules of diazobenzene chloride with one molecule of the phenylenediamines led to no result in the case of the ortho- and para-diamines. In the case of the meta-diamine a diazoamino compound was formed, but it was so unstable that it could not be isolated, breaking down with production of Chrysoïdine.—J. F. B.

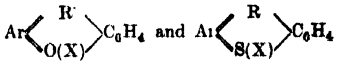
Diazo-salts; Action of water on ——. J. C. Cain and G. M. Norman. Chem. Soc. Trans., 1906, **89**, 19—26.



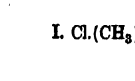
The decomposition products of the tetrazo salts prepared from *oo*-dichlorobenzidine and dianisidine are not the corresponding dihydroxy-compounds, as in the case of benzidine and tolidine, but are substances of a quinonoid character. In order to determine whether this difference is due to the presence of a substituted group in the ortho-position to the diazonium group, the authors examined a number of ortho-substituted diazo salts of the benzene series, especially those from which other investigators had failed to obtain hydroxy compounds. In every case examined, however, it was found possible to obtain the hydroxy compounds by the method described in Eng. Pat. 7233 of 1897 (this J., 1898, 269). In an addendum, J. C. Cain summarises the general results of his researches on the diazo reaction (Chem. Soc. Trans., 1902, **81**, 1412; 1903, **83**, 206, 470, 688; 1904, **85**, 7; 1905, **87**, 5; Ber., 1905, **38**, 2511; this J., 1903, 89, 548; 1905, 82).—A. S.

Cyanine Dyestuffs; Constitution of ——. W. König. J. prakt. Chem., 1906, **73**, 100—108.

The author considers that the formulæ proposed by Miethe and Book (this J., 1904, 712, 802) for Ethyl Red or Diethylisocyanine and for the blue Cyanine obtained from quinoline-methyl iodide and lepidine-methyl iodide are not satisfactory, and thinks it probable that these dyestuffs contain two hydrogen atoms less, and correspond to the formulæ:



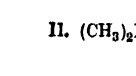
and



respectively, which account more satisfactorily for the analogy in properties which exists between them and the dyestuffs obtained from secondary amines and furfual or furfuracrolein. Both classes of dyestuffs combine with two atoms of iodine without essential alteration of shade, and possess the peculiar property of rendering photographic plates almost equally sensitive to all the visible rays of the spectrum. The dyestuff obtained by the author (this J., 1906, 63) from monomethylaniline and furfuracrolein possesses a pure blue shade in alcoholic solution, *i.e.*, it has the same shade as the above-mentioned blue cyanine from quinoline-methyl iodide and lepidine-methyl iodide, which is almost analogous in constitution, if one excepts the fact that the former compound contains a hydroxy group.—E. F.

Oxazine and Thiazine Dyestuffs; Nature of ——. A. Hantzsch. Ber., 1906, **39**, 153—159.

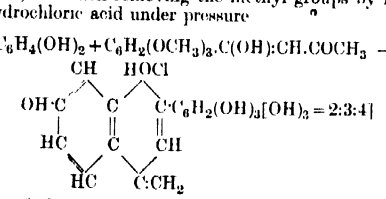
The author characterises Kehrmann's "oxonium" and "thionium" formulæ for the above dyestuffs (see Ber., 1905, **38**, 2577) as arbitrary and devoid of foundation. Dyestuffs of this class, *e.g.*, Meldola's Blue and Methylene Blue dissolve in water as neutral salts without hydrolysis, and the free bases are occasionally (*e.g.*, Methylene Blue) comparable in strength with the alkalis. On the other hand, all undoubted "oxonium" and "sulphonium" salts of the general formulæ



are entirely decomposed by water, and are therefore derived from very weak bases. The mother substances of Meldola's Blue and Methylene Blue fall under the above formulæ, according to Kehrmann's views, which are thus incompatible with the known facts. Further, the behaviour of Methylene Azure (see Formulæ I. and II.), and Binschedler's Green is in favour of the older assumption that these substances are quinonoid ammohium salts. Methylene Azure dissolves in water as a neutral salt. According to the azthionium formula (II.) it must, as a sulphonic acid chloride, be decomposed by water into the sulphonic acid and hydrochloric acid. The free base, which has been isolated by Bernthsen (Annalen, **230**, 180), must contain the group $OH.(CH_2)_3N:C_6H_3$, and cannot contain the group $>SO_2OH$, as it is a base and not a sulphonic acid.

I. $Cl.(CH_3)_2.N:C_6H_3\langle{}^{>N}_{SO_2}\rangle C_6H_3.N.(CH_3)_2$

Ammonium formula.



II. $(CH_3)_2N.C_6H_3\langle{}^{N}_{SO_2Cl}\rangle C_6H_3.N.(CH_3)_2$

Azthionium formula.

—H. L.

2-(2.3.4-*Trimethoxyphenyl*)-4-*anhydromethyl*-7-*hydroxy*-[1.4-*benzopyranol*] *and its derivatives.* C. Bülow and C. Schmid. Ber., 1906, **39**, 214—225.

In addition to the compounds previously described (this J., 1901, 704, 799, 1106), 2-phenyl substituted pyranol derivatives, containing two methoxy or hydroxy groups in the attached phenyl residue in the *o*- and *p*- position to the connecting carbon, as well as in the conjugated benzene nucleus, have also been prepared (see Bülow and Sautermeister, Ber., 1904, **37**, 354 and 4715). These substances, particularly the unmethylated bodies, are distinguished by good tinctorial properties. The authors have now prepared derivatives of 2-phenyl-4-anhydromethyl-[1·4-benzopyranol], which contain only one auxochrome hydroxyl group in the benzene nucleus and three neighbouring hydroxyls in the attached phenyl ring, by condensing resorcinol with 2.3.4-trimethoxybenzoylacetone, and then removing the methyl groups by means of hydrochloric acid under pressure

$C_6H_4(OH)_2 + C_6H_2(OCH_3)_3.C(OH):CH.COCH_3 \rightarrow$

CH HOCl

OH·C C C·$C_6H_2(OH)_3$[OH]$_3$ = 2:3:4]

HC C CH

HC C:CH_2

They find that the dyeings of this substance, apart from their deeper tone, do not differ materially from those of the resorcinol-benzoylacetone condensation product, since the auxochrome groups are not in the chromogen nucleus.—H. L.

Isohæmatein; a brown Dyestuff [*Logwood derivative*] *suitable for tissue printing.* L. d'Andiran. Bull. Soc. Ind. Mulhouse, 1905, **75**, 385–388.

Hummel and Perkin (this J., 1882, 448) showed that when hæmatein is dissolved in sulphuric acid, there is produced isohæmatein sulphate, $C_{16}H_{11}O_5(SO_4H)$, a compound almost insoluble in water, but resolved, by prolonged contact with this, into sulphuric acid and a "basic" sulphate of the formula $(C_{16}H_{12}O_6)C_{16}H_{11}O_5(SO_4H)$. The latter in dyeing properties differs considerably from the dyestuff from which it is derived, giving, for instance, in combination with iron oxide and chromic oxide dark brown, and with alumina and tin oxide, dull red colour-lakes. Owing to its too sparing solubility, however, it has little or no technical value. It is now found that the dyestuff in question when treated (in the form of a 15 per cent. paste) with sodium bisulphite (5 to 10 per cent. of a solution at 36° B.) and a little sodium acetate, is converted into an easily soluble compound, considered likely to be of great value for tissue printing. A suitable mixture for the application of the new compound consists of starch paste containing acetic acid, (150 parts), the compound "isohæmatein brown" in the form of paste (20 parts), chromium acetate (10 parts of a solution at 20° B.) and calcium acetate (4 parts of a solution at 16° B.). This is printed, and the printed tissues are steamed for 1½—2 hours and then rinsed and soaped. The bronze colour thus produced is, it is stated, very fast to light, air, soaping, &c., being, it is stated, much superior to the chrome lake of hæmatein in this respect. Compared with alizarin dyestuffs, the new compound has the advantages of printing without staining the "whites" and of penetrating well into the texture of the tissue, the latter property rendering it of especial value in the printing of raised (flannelette, &c.) and pile (velvets, &c.) tissues.

Isobrasilein; a claret coloured dyestuff [*Brazilwood derivative*] *suitable for tissue printing.* L. d'Andiran. Bull. Soc. Ind. Mulhouse, 1905, **75**, 388.

Isobrasilein sulphate (this J., 1882, 448), formed from brasilein by the action of sulphuric acid, followed by prolonged washing of the product with water, yields, on treatment with sodium bisulphite, a dyestuff-compound analogous to "isohæmatein brown" (see preceding abstract). This gives, when printed with a chromium mordanting salt and steamed, &c., a claret colour-lake which is considered to be of technical interest. As technically pure brasilein, unlike technically pure hæmatein, is not an article of commerce, the preparation of the "isobrasilein claret" compound cannot, at present, be undertaken on an industrial scale.—E. B.

English Patents.

Indigo-white; Manufacture of preparations of ——. O. Imray, London. From Farbw. vorm. Meister, Lucius und Brüning, Hoechst on the Maine, Germany. Eng. Pat. 4647, March 6, 1905.

The application of indigo-white, either dry or as aqueous pastes, meets with some difficulties, as dry indigo-white cannot easily be converted into paste form and is readily oxidised in the air. Moreover, the indigo-white in pastes tends to separate out in consequence of its crystalline structure and high specific gravity. According to the present invention, pastes are prepared, preferably from the moist indigo-white, in which the particles of the latter are surrounded by a viscid organic body soluble in water and of such nature as not to adversely influence the vat. Such bodies are syrupy mono-, di- and tri-saccharides, especially molasses. Thus indigo-white may be kneaded with molasses and, if preparations of a high percentage are desired, the product so obtained may be evaporated *in vacuo* to a syrup or solid. Or the indigo-white may be subjected to pressures of 200 atmospheres, preferably hydraulically, and kneaded with molasses. The concentrated sugar solutions have a preservative effect, rendering the usual preservatives unnecessary, but small quantities of fluorides or acids, such as formic acid, or of alkalis or alkaline-earths may be added. The indigo-white may be partially or entirely replaced by its soluble alkali salts. As an example of suitable proportions, 1000 parts by weight of indigo-white, containing 25 per cent. of water, made by pressing at about 200 atmospheres pressure, may be stirred in a kneading-machine with about 400 parts of viscid molasses, syrup, invert sugar or the like.—E. F.

Dyestuffs; Manufacture of brown Sulphide ——. Act.-ges. f. Anilinfabr. Fr. Pat. 357,986, Sept. 22, 1905.

A MIXTURE of *m*-phenylene- and *m*-toluylenediamine is heated with sulphur at a high temperature and the melt is subsequently treated with sodium sulphide.—H. L.

Dyestuffs varying from yellow to orange; Production of Sulphide ——. Act.-ges. f. Anilinfabr. Fr. Pat. 358,017, Sept. 25, 1905.

A MIXTURE of diformylbenzidine and *m*-toluylenediamine is heated with sulphur at temperatures exceeding 200° C. —H. L.

Dyestuffs; Production of blue to greenish-blue [Sulphide] ——. Badische Anilin und Soda Fabr. Fr. Pat. 357,600, July 29, 1905. Under Int. Conv., Jan. 21, May 25, 27 and 29, 1905.

THE process claimed consists essentially in (1), causing the following substances to react upon each other in any order:—(*a*) Quinone and its halogen derivatives; (*b*) thiosulphates, alkali sulphides, sulphuretted hydrogen, potassium thiocyanate, or other sulphurising agents; (*c*) monoalkylated or unsymmetrically dialkylated *p*-diaminothiosulphonic acids, or their mercaptans or disulphides, or the corresponding diamines in the presence of thiosulphates. Alternatively, (2), thioderivatives of hydroquinones containing one or more S R groups (R = an acid radical) or their mercaptans, sulphides or disulphides, may be isolated and condensed with the above-mentioned thiosulphonated *p*-diamines. The thio-derivatives in question are prepared by treating quinones, their derivatives and substitution products with a compound of the general foumula H.S.R., of which the most active are stated to be thiosulphonic, monothiocarboxylic, xanthogenic and thiocyanic acids. The operations specified are in general carried out in the presence of mild condensing agents; where necessary the dyestuff first formed is converted into a true "sulphide" dyestuff, by treatment with an alkali or alkali sulphide. Among the 19 examples given are the two following, which describe (1) the preparation of the potassium salt of hydroquinonemonothiosulphonic acid, and (2) the preparation of a blue sulphide dyestuff by condensing this substance with dimethyl-*p*-phenylenediaminethiosulphonic acid in alkaline solution.

(1) 43·2 kilos. of quinone (2/5 mol.) are dissolved in 150 kilos. of glacial acetic acid and allowed to drop, warm (40° or 50° C.), into a solution containing 150 kilos. of sodium thiosulphate (theory, 99·2 kilos.) and 200 litres of water at a temperature not exceeding 10° C. The solution is then saturated with potassium chloride and the potassium salt of hydro-quinone-thiosulphonic acid is filtered off. (2) To 150 kilos. of this substance, dissolved in 500 litres of water, are added, with cooling, a solution of 100 kilos. of dimethyl-*p*-phenylenediaminethiosulphonic acid in 500 litres of water and 60 kilos. of caustic soda (40° B). The mixture is allowed to slowly drop into a solution of 160 kilos. of caustic soda in 500 litres of water, which is kept at 60°—70° C. After standing for one hour, air is passed in and the dyestuff is isolated by acidifying the solution with hydrochloric acid. The product obtained is a violet powder which dissolves with a brown colour in dilute sodium sulphide solution.

The preparation of a number of sulphurised derivatives of hydroquinone and quinone is described in other examples, such as the monothiosulphonic acid, the mercaptan, the mono- and disulphide, the *a*- and *β*-dithiosulponic acids, the corresponding dimercaptans, and the tetrathiosulphonic acid of hydroquinone; benzoylhydroquinone-mercaptan, $C_6H_3(OH)_2S.CO.C_6H_5$

$$[(OH)_2 : S.CO.C_6H_5 = 1 : 4 : 2]$$

(from quinone and thiobenzoic acid in ethereal solution); the xanthate of hydroquinone, $C_6H_3(OH)_2S.CS.OC_2H_5$

$$[(OH)_2 : S.CS.OC_2H_5 = 1 : 4 : 2];$$

2.6.dichloroquinone and 2.6.dichlorohydroquinone mono- and dithiosulphonic acids, &c. The preparation of dyestuffs from several of these products is also illustrated by examples. In general, the dyestuffs obtained are stated to dye cotton from baths containing sodium sulphide in blue or greenish-blue shades of remarkable fastness to light, washing and acids. The fastness to chlorine is stated to be, at least for sulphide dyestuffs, very satisfactory.—H. L.

Dyestuffs varying from violet to blue from Indophenols derived from Paradiamines and α-Naphthol; Manufacture of Sulphide ——. C. Ris. Fr. Pat. 357,587, Sept. 9, 1905. Under Int. Conv., July 17, 1905.

ACCORDING to Fr. Pat. 284,387 of 1894 (which deals with the conversion of indophenols into sulphide dyestuffs) indophenols, such as the "well-known product derived from *a*-naphthol," which do not possess at least one phenol, cresol or phenolcarboxylic acid residue, are not suitable for conversion into sulphide dyestuffs. The present inventor on the contrary, finds that the indophenols derived from *a*-naphthol and *p*-diamines yield valuable products varying in shade from pure blue to violet, when heated with polysulphides, and claims the preparation of these dyestuffs.

For example, a press cake containing 20 kilos of the indophenol obtained from *p*-aminodimethylaniline and *a*-naphthol is dissolved in presence of 30 kilos. of crystallised sodium sulphide. To the clear solution 15 kilos. of sulphur dissolved in 40 kilos. of crystallised sodium sulphide are added. The mixture is evaporated until its boiling point reaches 115° C., and is then boiled under a reflux condenser for about eight hours. The dyestuff separates out and is filtered off, redissolved in sodium sulphide and reprecipitated in the usual way. *p*-Aminodiethylaniline, or *p*-aminomonomethyl- or ethyl-*o*-toluidine may be employed in place of *p*-aminodimethylaniline. Blue dyestuffs of different shades are obtained. The indophenols obtained from *p*-phenylenediamine or *p*-toluylenediamine ($CH_3 : (NH_2)_2 = 1 : 2 : 3$) yield dyestuffs which are stated to produce with only 3 per cent. a heavy shade of violet. The above dyestuffs possess, it is said, good affinity for cotton in the form of their leuco-bodies. The shades are developed by oxidation on the fibre, and are then stated to be fast to light, washing, alkalis, and weak organic acids, but not to mineral acids. The dyestuffs are soluble in alcohol and benzene.—H. L.

GERMAN PATENTS.

Lakes [from Azo Dyestuffs]; Process of preparing colour ——. F. Bayer und Co. Ger. Pat. 160,172, May 28, 1903. XIII*A*., page 189.

Dianthraquinone-imides; Process of preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 162,824, Oct. 30, 1903.

DIANTHRAQUINONEIMIDES, stated to be of value in the production of dyestuffs, are prepared by condensing halogenated anthraquinones with aminoanthraquinones in presence of metallic salts, such as cupric chloride. —T. F. B.

Dyestuffs; Process of preparing yellow Sulphide ——. Chem. Fabr. vorm. Weiler-ter-Meer. Ger. Pat. 163,001, April 19, 1904.

BENZIDINE or tolidine is heated with *p*-nitro-*o*-toluidine or with *o*-nitro-*p*-toluidine and sulphur, to a temperature of 220°—300° C. The dyestuffs are pure yellow in colour, and similar to those obtained from *m*-toluylenediamine with benzidine or tolidine (see Addition to Fr. Pat. 321,183 of 1902; this Journal, 1904, 57).—T. F. B.

Hydroxyphenylrosindulines [Azine Dyestuffs]; Process of preparing ——. Kalle und Co. Ger. Pat. 163,239, April 19, 1904. Addition to Ger. Pat. 158,077, Dec. 4, 1902 (see this J., 1905, 614).

HYDROXYPHENYLROSINDULINES are obtained by heating *p*-amino-*o*-cresol with benzeneazo-*a*-naphthylamine or benzeneazophenyl-*a*-naphthylamine and water or alcohol under a reflux condenser. The sulphide dyestuffs prepared from the product, are purer and more yellowish-red than those obtained when *p*-aminophenol is employed (compare Ger. Pats. 158,101, 160,789 and 160,815; this J., 1905, 614 and 886).—T. F. B.

Indigo and its Homologues; Process for preparing Chloro-derivatives of ——. Badische Anilin und Soda Fabrik. Ger. Pat. 162,670, May 3, 1904. Addition to Ger. Pat. 160,817, Feb. 24, 1904.

Organic acid chlorides are used for chlorinating indigo or its homologues, instead of the halogen compounds of phosphorus or sulphur, as in the principal patent (see this J., 1905, 1224).—T. F. B.

Dyestuff for Lakes; Process for preparing a Monoazo ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 163,055, Aug. 24, 1904.

p-Chlorobenzenesulphonic acid is chlorinated, nitrated and reduced; the resulting *o*-dichloranilinehomosulphonic acid ($SO_3H : NH_2 : (Cl)_2 - 1 : 2 : 4 : 5$) is diazotised and combined with β-naphthol, the dyestuff thus produced, being capable of forming clear red lakes when precipitated by a suitable metallic salt.—T. F. B.

[*Magenta*] *Fuchsin Preparations easily soluble in water* [*Triphenyl-methane Dyestuffs*]; *Process for preparing colourless* ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 163,104, Aug. 13, 1904.

Fuchsins containing 21 or 22 carbon atoms in their molecule are allowed to react for a long time, at the ordinary temperature, with concentrated hydrochloric acid; on addition of four mols. of water, colourless products are obtained, dissolving easily in water to stable, colourless solutions.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 120.)

Naphthylamine Claret; Discharging —— with sodium hydrosulphite, in the presence of alkaline iron compounds. L. Baumann and G. Thesmar. Bull. Soc. Ind. Mulhouse, 1905, 75, 374—378.

The alkaline discharge-mixture containing sodium hydrosulphite in solution and suspension, described in a *pli cacheté* dated 1903 (this J., 1905, 435; see also Addition to Fr. Pat. 297,570, this J., 1905, 87), suffers from the disadvantage, inherent to mixtures in which crystalline precipitates are present, of scratching the printing rollers. A mixture free from this defect, giving, moreover, like the mixture referred to, an excellent white discharge on tissues dyed with *a*-Naphthylamine Claret, is composed of 160 parts of British gum, 160 parts of precipitated calcium carbonate (64 per cent. paste), and 80 parts of china-clay mixed into a paste with 120 parts of cold water, to which are added 340 parts of concentrated sodium hydrosulphite-formaldehyde ("100 per cent."), 210 parts of caustic potash and, finally, after these compounds have been dissolved, 130 parts of an alkaline iron solution, prepared by dissolving 20 parts of ferric chloride in 20 parts of water and adding the solution gradually, while agitating carefully, to a solution of 24 parts of caustic potash and 40 parts of glycerin in 26 parts of water. The tissues printed with this mixture are steamed for three to four minutes. They are then thoroughly rinsed in water, soured, preferably with dilute ($\frac{1}{2}$—1° B.) hydrochloric acid, again washed, and soaped. Certain other metallic salts act similarly to iron salts in this connection, but mostly in a much lower degree. For example, the salts of tin and of nickel show considerable activity; those of cobalt, silver and mercury act very feebly; whilst the salts of most other metals are quite without action. Coloured discharges are produced with the white discharge-mixture in admixture with Flavanthrene (for yellow), Melanthrene (for grey), Indanthrene (for pale blues), Cyanosine, "soluble in spirit," dissolved in phenol and thus incorporated with the white discharge mixture (for pink) and Indigo. Indanthrene appears to be partially decomposed and is suitable only for pale shades of blue. Deeper shades of this colour may be obtained with Phenocyanine V, which is made into a paste with phenol before being added to the printing mixture. Other gallocyanine dyestuffs may be similarly applied.

C. Favre states that very fast coloured discharges may be obtained with the alkaline iron mixture recommended, by admixing this with sulphur dyestuffs; thus, a yellow discharge is produced with Immedial Yellow D (40 grms. per litre), a blue discharge with Immedial Sky blue (40 grms. of the dyestuff in the form of paste per litre), and a green from a mixture of the yellow and blue printing colours. The printed tissues, after being steamed for four minutes, are treated for a minute at the ordinary temperature with dilute (1 :100) hydrochloric acid and are then washed, &c.—E. B.

Naphthylamine Claret; Discharging —— with Sodium Hydrosulphite, in the presence of neutral iron compounds. L. Baumann, G. Thesmar and A. Hug (of La Société E. Zundel). Soc. Ind. Mulhouse, Procès-verbaux, 1905, 217—218.

Experience has shown that the process of discharging tissues dyed with a *a*-Naphthylamine Claret by means of a mixture containing sodium formaldehyde-sulphoxylate, a caustic alkali, and an alkaline solution of iron (see preceding abstract) is unsuitable for finely engraved patterns, probably owing to the alkali present in the mixture absorbing moisture during the steaming operation. A satisfactory discharge for such patterns is obtained from a suitably thickened mixture of sodium formaldehyde-sulphoxylate, an iron salt, and sodium nitrite, the effect on the azo dyestuffs being increased by the further addition to the mixture of sodium citrate or sodium ricinoleate. The sodium nitrite may be omitted from the printing mixture and applied to the tissues in the form of a preparation-solution.—E. B.

English Patents.

Washing and drying fabrics, fibrous substances and the like; Mechanism for ——. J. T. and J. S. Moore, Keighley, Yorks. Eng. Pat. 1120, Jan. 20, 1905.

An open-work cage, mounted to rotate horizontally, serves as a receptacle for materials which are to be washed, dyed, &c. Beating or lifting devices are fitted within the cage, for the purpose of raising the materials and distributing through them the washing, &c., liquors in which the cage is immersed, while it is being turned. The cage, with its contents, after the washing, &c., has been effected, is transferred to a chamber in which the materials are dried by a current of hot air.—E. B.

Aniline Black on vegetable fibres, yarns and fabrics; Production of ——. J. Singer and The Bradford Dyers' Association, Ltd., Bradford. Eng. Pat. 17,218, Aug. 25, 1905.

In order to produce animal black on vegetable fibres or fabrics, these are first impregnated with an aqueous solution of chromic acid, or of a mixture of chromates or bichromates with sufficient mineral acid to liberate chromic acid, and are then exposed to aniline vapour. A good black is said to be produced if 10 per cent. of chromic anhydride (CrO_3) is used, calculated on the weight of the material. The impregnation with aniline vapour is carried out by exposing the materials in a chamber at 80° to 100° C., into which the vapour, obtained by blowing air or steam through aniline oil, heating aniline oil, or heating a mixture of aniline oil and water to 90° C., are introduced. By keeping the chamber at the above-mentioned temperature, the process of formation of the black is quickened, and the shade produced is said to be rendered faster and more permanent to atmospheric influences. The material is subsequently washed and dried in the usual manner.—E. F.

Patterns, Designs or other similar markings in fabrics; Production of ——. C. W. Fulton, Paisley. Eng. Pat. 533, Jan. 11, 1905.

See Fr. Pat. 356,188 of 1905; this J., 1906, 17.—T. F. B.

Hydrosulphite preparation; Manufacture of a ——. Farbwerke vorm. Meister, Lucius und Brüning, Hoechst en Maine, Germany. Eng. Pat. 26,173, Dec. 15, 1905. Under Int. Conv., Dec. 28, 1904.

A HYDROSULPHITE compound directly applicable to vat dyeing is obtained by evaporating to dryness *in vacuo* a mixture of an alkali hydrosulphite, a ketone and ammonia. Thus, 1 litre of a 12 per cent. sodium hydrosulphite solution, 100 c.c. of acetone and 200 c.c. of a 25 per cent. ammonia solution may be used; the resulting white product is more stable than sodium hydrosulphite, but is also capable of reducing Indigo sulphonic acid in the cold (compare Eng. Pat. 6216 of 1904; this J., 1905, 194).

FRENCH PATENTS.

Silk and Textiles; Process of making artificial ——. H. E. A. Vittenet. Fr. Pat. 350,383, Dec. 8, 1904.

SEE Eng. Pat. 1686 of 1905; this J., 1905, 921.—T. F. B.

Silk; Recovery of solvents, especially Alcohol and Ether, from bobbins of artificial ——. J. Donge. First Addition, dated May 17, 1905, to Fr. Pat. 356,835 of April 21, 1905.

THE bobbins or supports on which the artificial silk is wound are provided with longitudinal perforations, in order to facilitate the introduction of the wash water in the process described in the main patent (see this J., 1906, 71).—H. L.

Tissues at full width; Apparatus for scouring, bleaching, dyeing, mercerising, &c. ——. C. L. Rothwell-Jackson and E. W. Hunt. Fr. Pat. 356,712, Aug. 5, 1905.

THIS invention relates to apparatus for bleaching, &c., tissues at full width (see Eng. Pats. 5409 of 1900 and 7872 of 1903; this J., 1901, 120, and 1903, 904), being more especially concerned with the provision of mechanism for automatically reversing the direction in which the tissues are drawn from the one to the other of two rollers, mounted side by side within a closed vessel The construction and manner of operation of the apparatus are as follows:—The tissue 17 (see Figs. 1 and 2) is wound upon one of two draw-rollers 13, a portion of it, long enough to encircle several times the other draw-roller, being unwound, passed round a pressure-drum 19, and wound upon the second draw-roller, while the carriage bearing the framework upon which the rollers are mounted is outside the keir. The carriage is then run on rails into the keir, its position being so adjusted that clutches 10 and 11, at the end of the shafts upon which the draw-rollers are mounted, engage with clutches 12 and 14, fixed upon the ends of driving shafts 15, extending through stuffing-boxes in the back of, and actuated from outside, the kier. The door of the keir is then closed; the scouring, &c., liquor to be applied, is introduced; and steam is admitted until the required pressure has been attained within the apparatus. The draw-roller upon which the tissue is to be wound is then set in motion. The tissue is thus unwound from the roller upon which it was originally placed and wound upon that which is driven. When almost the whole of it has been received upon the latter roller, the mechanism is reversed and the tissue is re-wound upon the first roller. This is accomplished automatically by means of a friction-pulley 20, fixed upon the shaft of the pressure-drum 19, which descends upon a friction pulley 9, loosely mounted upon the shaft which carries the roller from which the tissue is being withdrawn. When the two pulleys come into

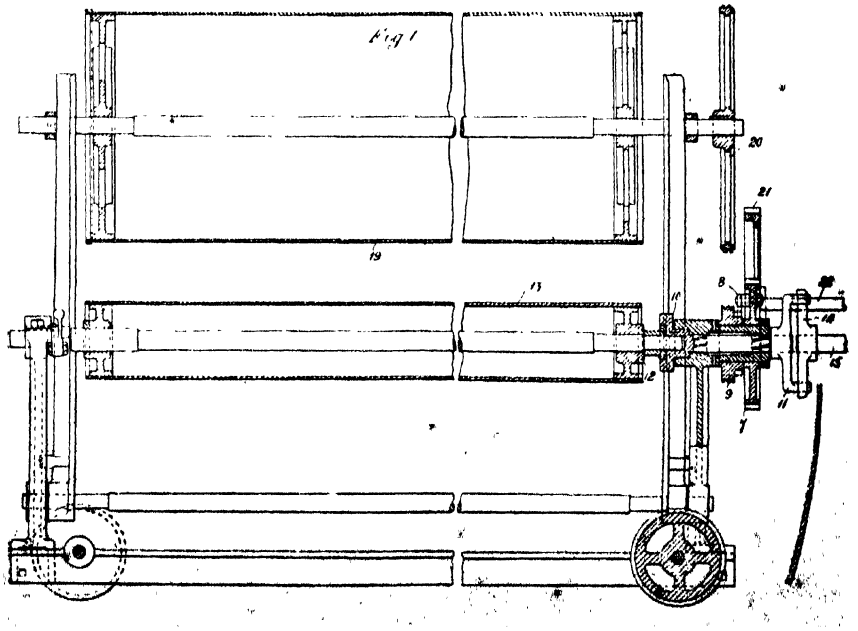

Fig. 2

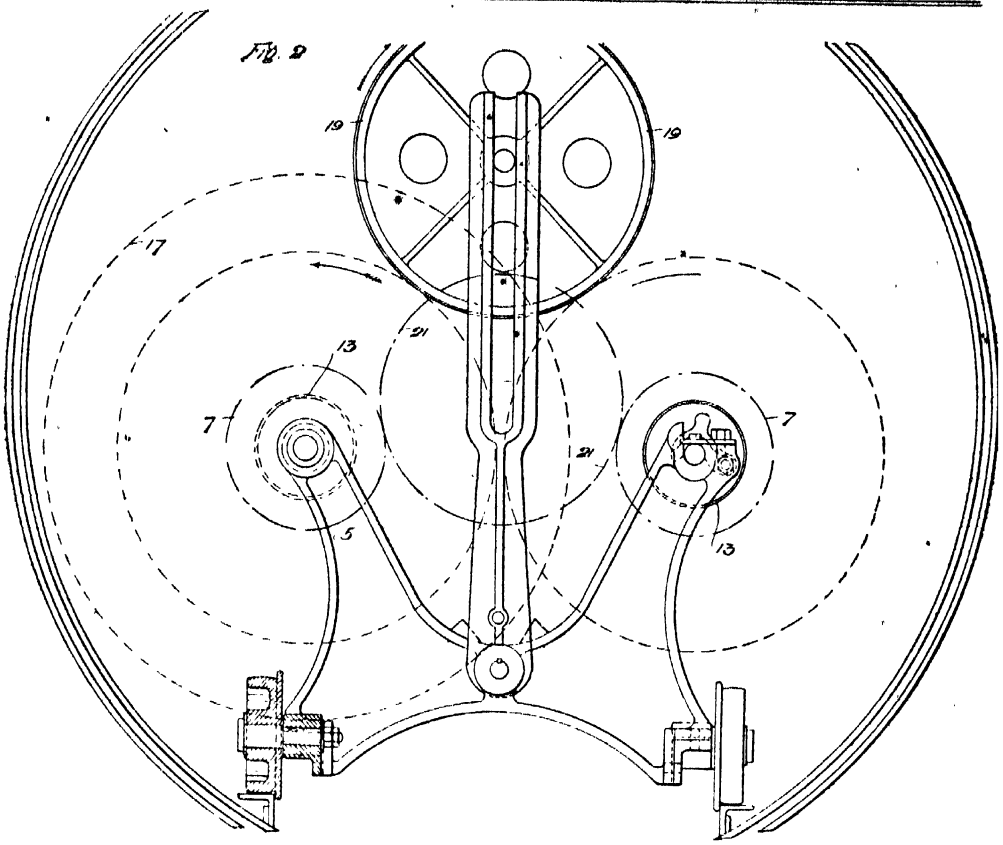

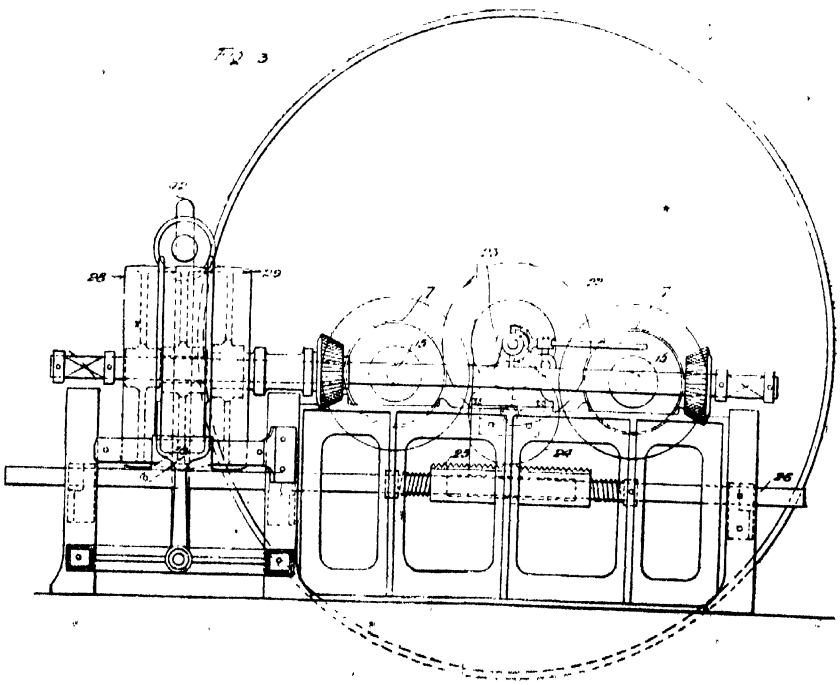

Fig. 3

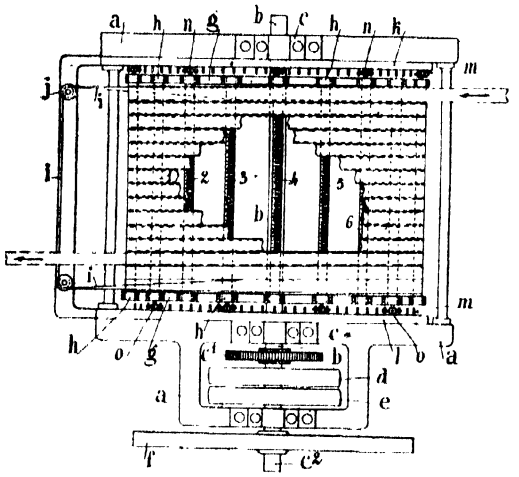

contact, the pulley 9 revolves, and, in doing so, brings a catch, fixed at its side to bear against a piece 8, projecting from a gear-wheel 7, loosely mounted on the shaft 15. The wheel 7, gears with a wheel 21, fixed upon a shaft 22, upon which is keyed a gear-wheel 23, engaging with a gear-wheel 24. The movement communicated to the latter is transferred to a rack 25, upon a rod 26, which is thus moved longitudinally, displacing by its motion a counterpoise 42, which controls the position of the driving strap upon one or other of the two driving pulleys 28 and 29. The draw-rollers are thus actuated in turn, during so long a time as is necessary for the completion of the scouring, &c., of the tissue under treatment.—E. B.

Washing Machine. G. P. Spittal. Fr. Pat. 357,573, Sept. 8, 1905.

A WASHING machine is claimed, which is stated to give the goods a rapid and thorough cleansing, as it almost exactly reproduces the process of washing by hand.—H. L.

Paper, Cloth and other Ribbons; Drum for drying ——. F. Mignot. Fr. Pat. 357,689, Sept. 12, 1905.

THE drum claimed (see figure) is mounted on a frame *a*. Its shaft *b*, resting in the bearings *c*, may be revolved by means of a cog-wheel c^1, and a secondary shaft c^2, to which a fixed and loose pulley *d*, and *e*, and a fly-wheel *f*, are attached. The drum is formed of two lateral plates *g*, on the circumference of which are bearings *h*, in which the smooth ends of screws 1, 2, 3, 4, 5, &c., may work. The threads of these screws run alternately to the right and the left, those of the screws marked with even numbers running to the right. On the drum thus formed by the plates and screws an endless ribbon or band of cloth *i*, is spirally wound passing at both ends on to guide-rollers *j*. Circular bars *k*, and *l*, which are fitted with horizontal pins *m*, are fixed on to the framework *a*, in close proximity to the plates *g*. The bar *k* has a greater diameter than *l*. The screws 1, 2, 3, 4, 5, &c., are furnished alternately on the right and left of the drum with a wheel or four-pointed star *n*, or *o*. The former series is worked by the toothed bar *k*, the latter by the bar *l*. Thus the rotation of the drum causes the screws also to revolve, the series 1, 3, 5, &c., turning in the same, and the series 2, 4, 6, &c., in the opposite direction to that of the drum. The threads of the screws are arranged to correspond with the width of the endless band.

The effect of this arrangement is stated to be (1) to diminish the tension on the endless band; (2) to direct the spirals obliquely yet in parallel lines over the drum, without overlapping. In this way a ribbon of cloth or paper 5 cm. wide is made to traverse a distance of over 125 m., when passing round a drying drum with a diameter of 2 m. and a width of 1, m.

The endless band *i* is required for drying delicate paper ribbons, such as those of cigarette paper, but may be dispensed with for woven ribbons, &c.—H. L.

Printing Plates or Casts; Process for preparing a plastic material and for making —— therefrom. L. Collardon. Fr. Pat. 350,376, Dec. 6, 1904.

SEE Eng. Pat. 27,090 of 1904; this J., 1905, 842.—T.F.B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 122.)

Hydriodic acid; Rapid method of preparing ——. F. Bodroux. Comptes rend., 1906, **142**, 279—280.

To 100 c.c. of warm distilled water containing suspended 60 grms. of barium peroxide, 50 grms. of iodine are added, in quantities of 4—5 grms. at a time, each portion being added only when the liquid has become decolorised after addition of the previous portion. The liquid is filtered with the aid of the pump, and the residue washed with about 80 c.c. of water. To the combined filtrates in a tall narrow cylinder, 50 grms. of iodine are added and dissolved, and a rapid stream of sulphur dioxide is then passed through till the liquid is decolorised. The liquid is filtered, and the filtrate concentrated, if necessary, by distillation. The reactions are: $BaO_2+I_2=BaI_2+O_2$; $BaI_2+I_2+SO_2+2H_2O=BaSO_4+4HI$.—J. T. D.

Silicic acid; α- and β-Forms of soluble ——. F. Mylius and E. Groschuff. Ber. 1906, **39**, 116—125.

BY neutralising a weak solution of sodium silicate, $Na_2Si_2O_5$, in the cold with hydrochloric acid, or by neutralising a solution of silicon tetrachloride with sodium hydroxide, a solution of silicic acid is obtained which passes freely through a dialysing membrane, and does not coagulate albumin. It is indifferent whether the acid be added to the silicate or conversely; but immediate complete mixture must be ensured. If there be local supersaturation, some at least of the dissolved silicic acid is in a colloidal form, and coagulates albumin. The authors regard the second, or β-form, as a polymer of the first, or α-form; the change from the α-form occurs slowly and partially in the cold, more rapidly and completely on heating, and is accompanied by a rise in the freezing-point of the solution and a slight increase in the electrical conductivity.—J. T. D.

Barium and Strontium Borates; Compounds of —— with the corresponding Chlorides. L. Ouvrard. Comptes rend., 1906, **142**, 281—283.

By fusing together boric anhydride and strontium chloride, the substance, $5B_2O_3,3SrO,SrCl_2$ is obtained. By adding strontia to the fused mass, no other compound containing chlorine is obtained, but the substances, B_2O_3,SrO and $B_2O_3,2SrO$, which yield respectively with water the compounds, $B_2O_3,SrO,2H_2O$, and $B_2O_3,SrO,4H_2O$. Strontium bromide—but not iodide—behaves similarly to the chloride, and barium furnishes compounds exactly analogous to those of strontium. Neither barium nor strontium borate combines so readily with the corresponding halides as does calcium borate.—J. T. D.

Nitrites and Nitrates; Production of —— by electrolytic oxidation of Ammonia in presence of Cupric Hydroxide. W. Traube and A. Bilts. XI.A., page 185.

Halogens; Use of Hydrogen peroxide for the Quantitative separation of ——. P. Jannasch and P. Zimmermann. XXIII. page 199.

Pyrites of an explosive character; Burning of ——, *and Apparatus therefor.* T. T. Best, S. A. Hollingsworth, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 7915, April 13, 1905.

GREEN pyrites is subjected to a preliminary heating operation on a floor under the same roof as the burners, and preferably arranged with a burner on each side, at a lower level than the floor. The pyrites dust or smalls made in the preheating part of the chamber is raked off the floors to undergo special treatment, and is not allowed to pass into the burners.—E. S.

UNITED STATES PATENTS.

Sulphuric anhydride; Process of making ——. R. Knietsch, Ludwigshafen on Rhine, Assignor to General Chemical Co., New York. U.S. Pat. 809,450, Jan. 9, 1906.

SEE Eng. Pat. 12,781 of 1901; this J., 1902, 772.—T. F. B.

Boric acid, &c.; Process of making —— [*Sulphur Burner*]. H. Blumenberg, jun., Daggett, Cal., Assignor to American Borax Co., Pittsburg, Pa. U.S. Pat. 809,550, Jan. 9, 1906.

A LONG horizontal sulphur-burning chamber, is supplied with air under pressure for continuous working; sulphur is supplied at intervals, the sulphur dioxide being allowed temporarily, during such time of supply, to pass into the outside atmosphere. The gas is led into water containing in suspension the finely-divided ore, whereby boric acid or the like is set free and is dissolved by the water in solution. The product is then separated by evaporation. (Compare U.S. Pat. 734,397 of 1903; this J., 1903, 950). —E. S.

Potash; Apparatus for extracting crude —— [*from Waste Waters of Beet Sugar Factories*]. G. W. Henry and F. W. Beale. U.S. Pat. 803,058, Oct. 31, 1905. XVI., page 191.

Silver Salt; Process of producing solutions containing pure ——. W. Bölsterli, Winterthur, Switzerland. U.S. Pat. 809,278, Jan. 9, 1906.

SEE Fr. Pat. 355,518 of 1905; this J., 1905, 1239.—T. F. B.

Metallic salts and oxides; Method of densifying and eliminating air and gas from masses of pulverulent ——. E. O. Bartlett and W. F. Gordon, Joplin, Mo. U.S. Pat. 809,354, Jan. 9, 1906.

DRY masses of pulverulent metallic salts and oxides are so treated in a revolving receptacle as to cause the component particles to constantly shift their relative positions. —E. S.

Stannic Chloride; Process of making ——. C. E. Acker, Niagara Falls, N.Y., Assignor to Acker Process Co., N.J. U.S. Pat. 810,454, Jan. 23, 1906.

STANNOUS chloride solution, obtained by acting upon tin with a "solvent containing chlorine," is subjected to the action of a gaseous or fluid mixture containing free chlorine, hydrochloric acid, and air or oxygen, the air being in sufficient proportion to prevent undue rise of temperature. The stannic chloride solution thus formed is caused to act on tin to reproduce stannous chlorine, which is again oxidised as before, and the concentrating process is repeated until a solution of stannic chloride is obtained of higher density than 1·800.—E. S.

Stannous Chloride; Process of making ——. C. E. Acker, Niagara Falls, N.Y., Assignor to Acker Process Co., N.J. U.S. Pat. 810,455, Jan. 23, 1906.

METALLIC tin is brought into contact with a solvent containing chlorine, and the stannous chloride thereby produced is subjected to the action of a gaseous or fluid mixture containing free chlorine with or without hydrochloric acid and air. The stannic chloride formed is reduced to stannous chloride by the action of tin, and the process is repeated until a stannic chloride solution exceeding a density of 1·8 is obtained, which is then again reduced and the solution allowed to cool to obtain crystallised stannous chloride.—E. S.

Tin; Process of making Chlorine Compounds of ——. C. E. Acker, Niagara Falls, N.Y., Assignor to Acker Process Co., N.J. U.S. Pat. 810,456, Jan. 23, 1906.

A SOLVENT for tin is subjected to the alternate and repeated action of metallic tin and of a gaseous body containing chlorine (see the two preceding abstracts), and the solution finally obtained is cooled by a medium out of contact with it, whereby, it is stated, "the tendency to produce metastannic compounds is avoided."—E. S.

FRENCH PATENTS.

Lead Chambers [*for Sulphuric Acid*]; *Auxiliary arrangements in* ——. J. Lagache. Fr. Pat. 350,363, Dec. 1, 1904.

PART of the gases are withdrawn from the hottest, or from any desired portion of the lead chamber, by an aspirator, and are conducted to a refrigerator, from which the portion that condenses is withdrawn. The cooled gases are then returned to the chamber. The ventilator or aspirator may be adapted, singly or in series, to any point of the apparatus, within the chambers, or in the connecting passages.—E. S.

Nitrogen; Manufacture of compounds of ——, *from the Air.* Siemens et Halske A.-G. Fr. Pat. 358,171, Sept 30, 1905.

THE constituents of the atmosphere are separated by known processes either chemically or mechanically, and the nitrogen is made to combine with carbides of the alkali metals or similar substances. The oxygen is mixed with a further quantity of air, and the mixture is subjected to the action of electricity for the production of oxides of nitrogen. —R. N.

Perborates; Process of preparing ——. Deutsche Gold- und Silber-Scheide-Anstalt vorm. Roessler. Fr. Pat. 350,388, Dec. 9, 1904.

SEE Eng. Pat. 26,790 of 1904; this J., 1905, 332.—T.F.B.

Oxygen; Preparation of —— *by the decomposition of oxygenated salts.* G. F. Jaubert. Fr. Pat. 350,377, Dec. 7, 1904.

AN oxygenated salt, such as a perchlorate or nitrate, is mixed with a very small proportion of a combustible substance, and the mixture is agglomerated and moulded into cartridges or the like, which, on being ignited, evolve oxygen with a little carbon dioxide or nitrogen. If desired, an inert substance, such as sand, may be added to the mixture, to moderate the rapidity of the combustion.—E. S.

Air; Process for the Liquefaction of —— *and the production of oxygen with partial recovery of the work expended.* R. Mewes. Fr. Pat. 358,236, Oct. 3, 1905.

AT a certain stage of the ordinary processes of compression and refrigeration of air, with partial recovery of work done, the gas expanded by aspiration, and consisting chiefly of nitrogen (having a vapour tension at —105° C. of 740 mm., that of oxygen being 142 mm.) is not returned in the circuit, but after being utilised in producing liquid air by refrigeration, is discharged, thereby leaving the gaseous mixture richer in oxygen. An aspirating pump is used with special connections for effecting the expansion of the compressed air.—E. S.

Chlorine; Manufacture of —— *by Electrolysis of Hydrochloric Acid.* E. F. Côte and P. R. Pierron. Fr. Pat. 358,245, Oct. 3, 1905. XI.A., page 186.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 122.)

ENGLISH PATENT.

Mica or Muscovy Glass; An improved process for finely comminuting ——. P. Dobler, Munich, Germany. Eng. Pat. 23,149, Nov. 10, 1905. Under Int. Conv., Jan. 23, 1905.

By this process the mica is first heated for several hours in a closed vessel, so that it is opaque on cooling, and is afterwards subjected in a closed vessel to the action of steam or hot water, and then ground.—W. C. H.

UNITED STATES PATENTS.

Glass; Manufacturing Window ——. L. Appert, Paris, France. U.S. Pat. 809,418, Jan. 9, 1906.

A HOLLOW "closed-top blank of glass" is first cast in the shape of a frustrum of a cone, which is then clamped with its open end downward upon a rotary platform. The blank is then transformed into a bulb or ovoid-shaped body by subjecting it to the action of heat in an oven, until it is rendered sufficiently plastic, and, whilst in that condition, imparting to it a rotary movement upon its axis, as well as a vertical up-and-down movement, at the same time that a current of air is being forced into its interior. The glass is now cooled and secured to a second rotary platform with its open end upwards, and then transformed into a plate or disc by reheating in an oven, and imparting to it, when sufficiently plastic, a rotary movement on its axis, after which the glass is annealed. —A. G. L.

Glass-Furnace S. O. Richardson, jun., Toledo, Ohio. U.S. Pat. 809,925, Jan. 9, 1906.

THE furnace comprises a heating-chamber in which a practically closed melting-pot is mounted. The pot is provided with a feed-port opening outside of the heating-chamber, and with an outlet-port discharging into the furnace, which is also provided with a plaining-chamber, and a conduit arranged to transfer metal from the pot into the plaining-chamber. An air-port is interposed between the heating-chamber and the plaining-chamber below the level at which the conduit crosses the port. Means are also provided for passing flame and gases through the heating-chamber and around the pot.—A. G. L.

Vitrified Brick Tile, and various shapes; Method of producing —— *[from slag of Copper-Smelting Furnaces]*. R. Baggaley, Pittsburg, Pa. U.S. Pat. 810,022, Jan. 16, 1906.

THE iron silicate slag from copper-smelting furnaces is run into moulds so as to completely fill them. At the rapidly cooling outer portions of the moulds the slag is confined whilst the hotter central parts are subjected to pressure, after which the article produced is allowed to cool and annealed by heating it in dry sand or slag.—A. G. L.

Ceramic Ware; Process of burning ——. B. E. Eldred, Bronxville, N.Y., assignor to Combustion Utilities Co., New York. U.S. Pat. 810,044, Jan. 16, 1906.

A STATIONARY mass of the ceramic ware is burnt by means of a voluminous slow-burning flame, produced by forcing gases containing oxygen, diluted with products of combustion, through a bed of solid fuel, the air necessary for the combustion of the gas produced being pre-heated in a regenerator. The volume of the flame may be enlarged as the burning of the ware proceeds, or else the amount of burnt gases used as diluent may be varied so as to give alternately a reducing or oxidising flame.—A. G. L.

(*Continued from page* 123.)

Lime-Sand Bricks; Hardening process in the manufacture of ——. R. Seldis. Z. angew. Chem. 1906, 19, 181—183.

FOR the preparation and mixing of the materials three methods are used—the quicklime, the slaked lime, and the heating process. In the first, the moisture of the sand effects the slaking of the lime; in the second, the lime is slaked to the dry hydrated condition, ground to a powder, and mixed with the proper amount of sand; and in the third, weighed amounts of ground quicklime and dry sand are mixed together for 22—25 minutes in a closed vessel to which steam and water are admitted to slake the lime. After any of these processes the materials are taken to the press, and from it the objects are removed to a wagon, which is pushed into the hardening chamber, and exposed to a steam pressure of eight atmospheres for eight to ten hours.

Two hypotheses have been advanced to explain the process of hardening in this chamber. The one assumes that in the production of the pressed ware, each grain of sand must become coated with a thin skin of lime, and that a cementation takes place in the hardening chamber. The second assumes that the hollow spaces between the individual grains of sand are filled with lime, which then effects the cementation. From his own experiments the author considers the following to be the explanation of the process:—At the usual pressure and temperature prevailing in the hardening chamber, a portion of the silicic acid goes over to the gelatinous or colloidal condition. The hydrated lime present in the object reacts with this silicic acid, with a simultaneous union with water, and forms a calcium hydrosilicate, $CaH_2SiO_4 + 2H_2O$, which causes the hardness of the brick.

This theory explans why bricks cannot be made with either a very small or a very large addition of lime, and why the amount of lime required is dependent upon the quantity of soluble silicic acid contained in the sand, and further why the best bricks are obtained when the calcium hydroxide and the free silicic acid are in molecular proportions. The fact that bricks cannot be made from pure quartz-sand and lime, is because the silica in such a form will not combine with the lime at the oven temperature. Felspar sand is used most for the manufacture; it contains 5—7 per cent. of soluble silicic acid, and this, with a lime averaging 85 per cent. of calcium oxide, corresponds with 4—5 cwt. of lime to 2½ cb. m. of sand, a ratio used in practice. The theory also shows that if a hard water containing much lime is used, this will not become chemically combined in the hardening process. It also explains why, when the heating process already referred to is employed, it is necessary to pass the pressed objects at once to the hardening chamber, to avoid interruption of the chemical reaction, which begins in the heating process. Variations in the steam pressure of the hardening chamber should be avoided, and for this purpose a registering pressure-gauge is recommended.—W. C. H.

ENGLISH PATENTS.

Cork Compositions; Manufacture of ——. F. Matas y Rodés, Calella, Spain. Eng. Pat. 248, Jan. 5, 1906.

IN making agglomerates of particles of cork or cork dust, cemented together by a glutinous material, the mixture is forced into moulds fitted into presses in such a manner that the mass is able to receive a mechanical pressure in at least two different directions at right angles to each other. The two pressures may be applied either simultaneously or consecutively (compare Fr. Pat. 349,782; this J., 1905, 734).—J. F. B.

Cork Compositions or agglomerates; Manufacture of ——. F. Matas y Rodés, Calella, Spain. Eng. Pat. 249, Jan. 5, 1905.

THE ground cork is saturated with a solution of resinous

or vegetable glue and subsequently dried. The particles are then separated thoroughly, one from another, and are introduced into moulds which are capable of withstanding high pressures at elevated temperatures. The action of pressure and heat upon the saturated cork softens the glue and causes the particles to adhere together in a solid mass. If desired, a certain proportion of gum-lac or resin may be added to the mass to impart greater rigidity and cohesion.—J. F. B.

Lime Burning and the recovery of Power gas as a by-product; Impts. in and apparatus for ——. The Chalk Power Gas Syndicate, Ltd., and H. S. Stoneham, London. Eng. Pat. 2684, Feb. 9, 1905.

THE apparatus described is intended to reduce the carbon dioxide, derived from limestone by its conversion into quicklime, to carbon monoxide to yield a useful power gas. The apparatus consists of three juxtaposed chambers, one of which acts as a gas producer, the next as the lime-kiln, and the third as a gas-reducer. Carbonaceous fuel (anthracite or coke) is burned in the producer, a blast of air or air and steam being introduced below the grate. The gas produced passes into the kiln and burns there. At a point about two-thirds of its height from the top of the kiln, boshes are arranged to form a constriction of the area, so that, as the lime passes this constriction, it leaves an annular space in which the carbon dioxide and products of combustion collect, and pass through a port into the gas-reducer. This chamber contains carbonaceous material (coke or anthracite) which is raised to incandescence by an air blast, and effects the reduction of the carbon dioxide introduced from the kiln, to carbon monoxide. The reduced gases, containing also hydrogen derived from the decomposition of the steam introduced into the gas producer, are led away from the gas reducer by a pipe controlled by a valve. The kiln chamber is provided with a secondary air supply for the combustion of the gases derived from the producer.—W. C. H.

Fire Resisting; An improved solution for rendering combustible materials [*Wood, Textile Fabrics, &c.*] ——. A. W. Baxter, London. Eng. Pat. 5209, March 13, 1905.

THE impregnating solution is made by dissolving about 12 parts of ammonium phosphate and 1 part of boric acid in 87 parts of water. The claims also include the treatment, by impregnation with this solution, of wood, textile fabrics, and other materials to make them fire-resisting. It is said that materials so treated do not absorb water, prevent metals in contact with them from corroding, and are also preserved.—W. C. H.

Road-making; Impts. in ——. J. C. Butterfield, London. Eng. Pat. 9350, May 3, 1905.

PITCH or asphaltum, or a mixture of the two, is melted in an iron pan, and sufficient fine granite, flint or sharp sand, and limestone or chalk stirred in to give a pasty mixture. After cooling, this is broken up and mixed with more of the mineral ingredients, preferably so as to give a mixture having the composition: Fine granite, 50 per cent.; flint or sharp sand, 25; limestone, 10; and asphaltum or pitch, 15. This mixture may then be powdered so as to pass a 20-mesh sieve. Or, it may be ground only sufficiently to pass through a ¼ in. mesh providing that the fine dust produced in grinding is also used. It is next mixed with from 3 to 10 per cent. by weight of a solution consisting of 90 parts of petroleum or shale oil and 10 parts of commercial nitro-benzol. The whole is thoroughly mixed and wetted, and laid on the roadway to a depth of 2 in., after which the larger "metal" (granite or flint cubes of about 2 in.) are rolled in by means of a steam roller. After hardening for from 48 to 60 hours a waterproof and dustless road is obtained. Or else a mixture of the rubble and binding material may be laid on the roadway. Or, finally, a mixture of rubble and binding material may be moulded into blocks.—A. G. L.

Siloxicon; Process of treating ——. B. Seaboldt, Salt Lake City, U.S.A. Eng. Pat. 17,890, Sept. 4, 1905. Under Int. Conv., Jan. 6, 1905.

SEE U.S. Pat. 796,459 of 1905; this J., 1905, 971.—T. F. B.

FRENCH PATENTS.

Asphalt-compositions for roads, pavements and flagstones, and process of making the same. E. Mathis. Fr. Pat. 358,050, Sept. 26, 1905. Under Int. Conv., Oct. 11, 1904.

CRUSHED or powdered slate, burnt or unburnt, is heated and agitated with a quantity of pitch not exceeding that of the slate. The pitch may be neutralised if necessary by adding lime. Suitable proportions are:—Slate, 2 parts; pitch, containing 5 to 10 per cent. of lime, 1 part. The pitch and slate may also be mixed cold and rammed into position by means of hot irons. Both materials may be replaced by kindred substances, *e.g.*, magnesium silicate and heavy tar fractions.—A. G. L.

[*Cement*] *Kiln; Rotary* ——. W. R. Warren. Fr. Pat. 358,227, Oct. 3, 1905.

THE kiln is divided longitudinally or obliquely into two or more compartments by one or more partitions, so as to ensure better drying and burning of the materials. Fuel and air may be introduced by one or more openings in the lower end of the kiln.—A. G. L.

X.—METALLURGY.

(*Continued from page* 126.)

Gold and Silver Ores; Importance of fine-grinding in the Cyanide treatment of ——. F. C. Brown. Bi-Monthly Bull. Amer. Inst. Min. Eng., 1906 [1], 17—23.

THE author's experience with gold and silver ores in the Ohinemuri district, North Island, New Zealand, points to the importance of fine-grinding in the treatment of comparatively low-grade ores. It was found that with ore crushed to pass screens with from 30 to 40 holes to the linear inch, a considerable quantity of gold and silver in the sands was left undissolved by the cyanide solution, the proportion thus lost increasing with the coarseness of the sands. The process recommended by the author consists in:—(1) Grinding the ore in tube-mills until about 90 per cent. will pass a 200-mesh screen, followed, if necessary, by amalgamation. (2) Agitation of the ore pulp with weak cyanide solution in a tall vat, of comparatively small diameter, with a conical bottom, in the centre of which is fitted an "air-lift" pump for agitating the mixture of ore and cyanide solution. (3) Separation of the solution by settling and passing the supernatant liquid through a filter-press. Except in cases where minerals are present from which the gold cannot be extracted by cyanide solution, mechanical concentration may probably be dispensed with, provided the ore be ground exceedingly fine.—A. S.

[*Gold*] *Ore; Fine grinding of —— by tube-mills, and Cyaniding at El Oro, Mexico.* G. Caetani and E. Burt. Bi-Monthly Bull. Amer. Inst. Min. Eng., 1906 [1], 83—135.

THE authors give an account of an exhaustive investigation as to the economical limit to which the fine grinding of gold ore by tube mills can be carried. The work included also determinations of the influence of various conditions on the efficiency of the tube-mills, and also of the effect of certain substances (lead acetate, mercuric chloride, on the extraction of gold and silver by cyanide solution; lead acetate was found to have a markedly favourable influence on the extraction of both gold and silver. The general conclusion drawn by the authors is that the problem of extracting the gold and silver values from the El Oro ore by cyanide is mainly a mechanical one, the extraction being largely dependent upon the state of division of the ore; and they consider that in the near future the ore will be ground to slime, or to the finest state of division possible economically (see also this J., 1904, 1030).

—A. S.

Fire in Pyritous Mines; Controlling and extinguishing ——. L. T. Wright. Eng. and Mining J., 1906, 81, 171—172.

THE author shows that fires in pyritous mines are probably

due to the action of oxygen on the pyrites in the presence of moisture, the latter acting as an oxygen-carrier. Based on this view, he devised the following method for avoiding such fires or, at least, preventing them from extending to the workings. Powerful fans are fitted up at certain of the entrances to the workings, which are closed by doors and provided with ducts for the air driven along by the fans. In this way, a pressure slightly above that in the outside atmosphere is maintained in the workings, and gases from the interior of blocks of ore or filling material are kept from penetrating into the workings; the gases are thus caused to accumulate in the interior of the blocks, where they ultimately extinguish the fire.—A. S.

Lead Sulphide and Calcium Sulphate; Experiments on the metallurgical behaviour of a mixture of ——. F. O. Doeltz. Eng. and Mining J., 1906, **81**, 175—176.

In Eng. Pat. 17,580 of 1901 (this J., 1902, 349) it is stated that a mixture of lead sulphide and calcium sulphate reacts at a dull red heat, say about 400° C., forming lead sulphate and calcium sulphide. The author describes experiments showing that this reaction does not take place even at temperatures up to 1030° C., if the mixture be heated in a current of carbon dioxide or nitrogen. On the other hand, when lead sulphate and calcium sulphide are brought into contact, the tendency is to form lead sulphide and calcium sulphate. It is probable, therefore, that the lead sulphate obtained together with lead oxide when a mixture of galena and gypsum is heated in presence of air, is due not to a double decomposition of lead sulphide and calcium sulphate, but to the action of sulphuric acid "produced by catalysis" on the lead oxide formed by oxidation of the galena.—A. S.

Thorium and Aluminium; Alloy of ——. O. Hönigschmid. Comptes rend., 1906, **142**, 280—281.

The author has previously shown that by reduction of thoria by silicon in the electric furnace, by direct combination of silicon and thorium in presence of aluminium *in vacuo* at 1000° C., or by reducing a mixture of potassium silicofluoride and thorium potassium fluoride by aluminium, a silicide of thorium is produced, crystallising in quadratic plates resembling graphite, and having the composition $ThSi_2$.

Similarly, the reduction of thoria in the electric furnace by aluminium, the direct combination of thorium and aluminium *in vacuo*, or the reduction of thorium potassium fluoride by aluminium, yields an alloy of thorium and aluminium. This crystallises in long hexagonal prismatic needles, having the colour and metallic lustre of aluminium, and has the formula $ThAl_3$. It is permanent in the air, burns in air or oxygen at a red heat, combines vigorously with halogens, and is attacked by mineral acids. Alkalis in aqueous solution do not affect it, but attack it when fused with it.—J. T. D.

Silver; Determination of —— in large quantities of silver coins. C. Hoitsema. XXIII., page 200.

Tin, Monazite and Xenotime in Tringganu. C. G. Warnford Lock. Bull. (17) of Inst. Min. and Met., 10.

Tringganu is a little known Independent Native State on the East Coast of the Malay Peninsula, between Pahang and Kelantun. The coast is flat and devoid of minerals, and consists of dense jungle, swamps, and rice gardens. The trees are of rapid growth and useless as fuel.

Running parallel with the coast, at about 20 miles distance, is a range of hills, at the foot of which is the seat of the tin-mining industry of Kemaman. The alluvial soils and gravels here rest immediately on the granite bed rock. Everywhere these gravels carry stream tin and, in many cases, the shallowness of the deposit is more than atoned for by the richness of the ground. The extent of the old alluvial workings is great and is due to the Chinese. Not only did they mine, but they smelted upon the spot, as is seen by the accumulation of slags, still containing much tin.

No readily accessible alluvial tin deposits are left; but where there is either no water or too much of it, there is good prospect of success for competent engineers. The most interesting and valuable feature of these alluvial fields is the occurrence of monazite and xenotime. On one concession, worked for tin by Chinese, the writer found that 50 per cent. of the material collected in the sluices was monazite, and in another instance xenotime could be abundantly gathered (with zircons, monazite, cassiterite, ilmenite, &c.) from pot holes in the granite bed of the stream. All these properties are owned by wealthy Singapore merchants. At varying elevations in the foot hills occur lodes of tin stone, but do not exist as profitable ore bodies in the granite itself. But occasionally fine-grained cassiterite is found widely disseminated through the granite. The only profitable ore-bodies hitherto found are in the shales overlying the granite. [T.R.]

Zinc Industry in 1905; *Silesian* ——. Mining World (Chicago), Feb. 3, 1906.

It is estimated by Paul Speier, of Breslau, Prussia, that the spelter production of Upper Silesia in 1905 was 128,000 metric tons. The extraordinary demand from consumers, especially in the second half of the year, resulted in an advance in price to the highest point since 1899, and before that since 1873.

In view of the steadily increasing use of blende by the smelters, which results in an enrichment in the zinc content of the charge for their furnaces, the Silesian smelters are gradually changing their furnaces from the old to the Rhenish type. At the end of 1905 there were in use 316 furnaces, with about 12,500 muffles of the old type, with a single row of muffles, and 162 furnaces, with about 15,000 muffles of the Rhenish type, with several rows of muffles.

Important experiments have been made upon the treatment of low grade calamine ore, with a view to the extraction therefrom of a rich zinc oxide, which can then be passed on to the smelting process. An experimental plant of this character is in operation at the Elizabeth dressing works. The Zinkgewinnungsgesellschaft m.b.H., of Berlin, has purchased a large dump of calamine tailings, containing about 10 per cent. of zinc, for the purpose of recovering the metal.

The production of sheet zinc in Silesia in 1905 was about 54,000 metric tons.

For the roasting of zinc blende there are at present 12 plants, having 128 furnaces, the gases from which are wasted; 144 furnaces, the gases from which are utilised for the manufacture of sulphuric acid; and 10 furnaces, the gases from which are utilised for the manufacture of sulphurous acid.

Some experiments have been made at the Rosamundehütte upon the employment of carborundum in the mixture for muffle manufacture. This gave favourable results. [T. R.]

Spelter Production in 1905. Eng. and Min. J., Feb. 3, 1906.

According to the statistics of Henry R. Merton and Co., Ltd., the production of spelter in Europe and America in 1905 was 647,585 long tons, against 615,290 in 1904, and 562,325 in 1903. This represents practically the total spelter production of the world, the only omissions being the outputs of Sweden and Norway, Saxony and Australia, which in the aggregate are comparatively insignificant. The total zinc production of the world is, however, about 7·5 per cent. larger than the spelter production, because of the important output of zinc oxide produced directly from ore in the United States. The statistics in detail are as follows:—

Country.	1905.	1904.	1903.
Belgium	143,165	137,780	139,000
Rhine district	66,185	64,360	61,215
Holland	13,550	12,895	11,515
Great Britain	50,125	45,490	43,415
France and Spain	49,575	48,310	41,760
Silesia	127,895	128,695	116,885
Austria and Italy	9,210	9,100	9,025
Poland	7,580	10,440	9,745
United States	180,360	168,220	129,995
Total	647,585	615,290	562,325

[T.R.]

ENGLISH PATENTS.

Metalliferous Ores; Apparatus for separation of liquids from solids, especially for use in the treatment of ——. W. H. Lomas, Johannesburg. Eng. Pat. 149, Jan. 3, 1905.

AN endless porous belt is made to pass around a hollow perforated cylinder, or suction-drum, placed within a receptacle containing the mixture of liquids and solids. The cylinder is provided with a stationary curved plate or damper covering those apertures which are not covered by the porous belt. A partial vacuum is created within the suction-drum, whereby the liquid to be removed is drawn into it, the solid being at the same time deposited upon the belt, from which it is subsequently removed by a fluid or gaseous current which is forced through the belt as it passes over a separate pipe or drum.—J. H. C.

Ore Concentration. H. L. Sulman, H. F. K. Picard and J. Ballot, London. Eng. Pat. 7803, April 12, 1905.

Ore and Pulp washing and separating machines; Centrifugal ——. S. Fawns and F. E. Davies, London. Eng. Pat 21,755, Oct. 25, 1905.

THE separating chamber is mounted on a hollow shaft, through which the ore or pulp is introduced; it is made in two parts which can be rotated separately. In the peripheries of the two halves of the chamber are ports or outlets which can be opened or closed at will by rotating only the upper portion of the chamber. The ore or pulp passes from the hollow shaft through radial openings into the separating chamber, below a deflecting or distributing plate mounted on the shaft at about the level of the outlets already mentioned. On the inner wall of the separating chamber near these outlets are webs or wings which agitate the ore or pulp and guide the separated solid material through the openings. The liquid rises above the distributing plate and is discharged through openings in the upper half of the separating chamber. Separate collecting channels are provided outside the chamber for the liquid and solid materials respectively. —A. S.

Ores; Smelting ——. J. Savelsberg, Papenburg-on-Emms, Germany. Eng. Pat. 3191, Feb. 15, 1905.

SEE Fr. Pat. 351,535 of 1905; this J., 1905, 894.—T. F. B.

Bronze; Manufacture of ——. G. E. Buttershaw, Barrow-in-Furness. Eng. Pat. 792, Jan. 14, 1905.

AN alloy consisting approximately of copper, 40 parts; zinc, 41; nickel, 10; lead, 3·5; phosphor-tin, 1; and aluminium, 0·15 part, is prepared by melting and combining the components in stages as described in the specification.—J. H. C.

Tin Slags; Smelting of ——. L. Parry, Huddersfield. Eng. Pat. 7154, April 5, 1905.

"FOUL" tin slag, *i.e.*, slag containing 3 per cent. or more of tin, is "cleaned" by smelting it in a furnace, preferably a water-jacketed blast-furnace such as is used for lead smelting, the charge being composed as follows:—(1) Foul tin slag; (2) iron oxide in such quantity as will give a highly basic slag containing more than 40 per cent. of ferrous oxide—"tap cinder" (iron slag) is preferably used for this purpose; (3) lead ashes, slags, drosses or oxidised lead ores in such proportion as to give an alloy containing about 20 per cent. of tin; (4) a source of arsenic or sulphur, such as mispickel, arsenical drosses, spent oxide, or lead sulphate, enough being used to form an easily fusible compound with any metallic iron reduced; (5) a mixture of gas coke and furnace coke in such proportion as to obtain the maximum output, gas coke increasing the reducing action, whilst furnace coke increases the speed of smelting. The slag produced in this way contains only ¾ to 1½ per cent. of tin. The sulpharsenide of iron, lead, tin, copper, cobalt or nickel also produced is crushed, roasted and re-smelted until it becomes rich enough to be worked up for copper, cobalt or nickel. —A. G. L.

Iron Briquettes; Producing ——. L. Weiss, Budapest, Hungary. Eng. Pat. 17,844A, Sept. 4, 1905.

SCRAP-IRON is mixed with fluxes, *e.g.*, lime, ferromanganese, ferrosilicium, and with graphite or charcoal. The mixture is moistened with lime-water, pressed, and allowed to solidify, electrolytic actions generating heat taking place. After cooling, the briquettes form compact waterproof pieces yielding on smelting "94 to 96 per cent. excellent iron."—A. G. L.

UNITED STATES PATENTS.

Iron or Steel; Manufacturing ——. E. Fleischer, Dresden-Strehlen, Assignor to J. E. Goldschmid, Frankfort, Germany. U.S. Pat. 809,291, Jan. 9, 1906.

SEE Fr. Pat. 343,701 of 1904; this J., 1904, 1032.—T.F.B.

Steel; Process of hardening ——. R. A. Hadfield, Sheffield. U.S. Pat. 810,531, Jan. 23, 1906.

SEE Eng. Pat. 25,973 of 1902; this J., 1903, 1296.—T.F.B.

Furnace; Roasting ——. O. Hofmann, Argentine, Kans., Assignor to The United Zinc and Chemical Co., Kansas City, Mo. U.S. Pat. 809,953, Jan. 16, 1906.

THE furnace comprises a number of superposed hearths and a rotating, vertical, central hollow shaft or pipe extending through them. Hollow radial arms project from the central shaft into the hearths. Inside the hollow shaft is a water-supply pipe having branches through which water is sprayed into the hollow arms, which are provided with passages through which steam escapes into the central shaft. The lower end of the shaft communicates with a discharge pipe, below which is a trough, to prevent accumulation of condensed water.—A. S.

Furnace; Duplex Smelting ——. R. Lindemann, Osnabruck, Germany. U.S. Pat. 810,063, Jan. 16, 1906.

SEE Eng. Pat. 26,093 of 1904; this J., 1905, 1238.—T.F.B.

Minerals; [Flotation] Process of separating ——. E. B. Kirby, Rossland, Canada. U.S. Pat. 809,959, Jan. 16, 1906.

THE pulverised mineral is mixed with a considerable quantity of water and with a substance immiscible with, but lighter than water, *e.g.*, a solution of bitumen in light hydrocarbon (kerosene), which, in presence of water, will adhere to some of the mineral particles but not to others. The mass is violently agitated and then allowed to settle, whereby the particles which have become coated with the bitumen solution rise to the surface, this separation being assisted by gentle agitation and by blowing in a current of a gas. The layer of floating matter is removed, and washed, and the mineral particles are separated by filtration and then heated to recover the light hydrocarbon.—A. S.

Ores; Process of treating ——. J. Savelsberg, Papenburg, Germany. U.S. Pat. 810,572, Jan. 23, 1906.

SEE Fr. Pat. 351,535 of 1905; this J., 1905, 894.—T. F. B.

Kilns; Process of preventing the formation of "Scaffolds" in ——. T. C. King, New York, Assignor to National Metallurgic Co., Jersey City, N.J. U.S. Pat. 810,059, Jan. 16, 1906.

THE scaffolds or rings of fused materials are removed from the sides of the kiln by charging calcium fluoride into the kiln against such rings and maintaining them at a high temperature, with the result that they are fluxed or melted down.—W. H. C.

Copper; Refining ——. R. Baggaley, Pittsburg, Pa., C. M. Allen, Lolo, Mont., and E. W. Lindquist, Chicago, Ill. U.S. Pat. 810,249, Jan. 16, 1906.

THE process consists in injecting, by means of an air-blast under pressure, sawdust mixed with "fusible hydrocarbon" into a molten bath of black or blister copper in a converter, before that stage of oxidation has been reached wherein appreciable quantities of copper suboxide are produced.—A. S.

Slag; Saving Metal Values from ——. C. M. Allen, Lolo, Mont. U.S. Pat. 810,364, Jan. 16, 1906.

THE slag and matte are withdrawn from below the surface of the molten bath in the furnace, and overflow through a spout into a fore-hearth or separating chamber. The heat of the matte and slag is conserved by covering them during their passage from the furnace to the separating-chamber with a "practically air-tight conduit" of heat-radiating material.—A. S.

Vitrified Brick, Tile and various shapes; Method of producing —— [*from Slag of Copper Smelting Furnaces*]. R. Baggaley. U.S. Pat. 810,022, Jan. 16, 1905. VIII., page 181.

FRENCH PATENTS.

Steel; Use of Blast-furnace Gas in the working of ——. P. L. Hulin. Fr. Pat. 350,399, Dec. 14th, 1904.

THE gas issuing from the blast-furnace is divided into two streams, one of which, after passing through a purifier, is employed to operate the motor which works up the steel into ingots after fusion; the other stream also passes through a purifier, and, after enrichment with carbonic oxide produced in a separate coke-furnace, is employed for fusing the materials to be converted into steel. For this part of the process a mixture of 85 to 90 parts of blast-furnace gas with 10 to 15 parts of gas from the coke-furnace is recommended.—J. H. C.

Furnace; Crucible ——. E. Hausmann. Fr. Pat. 358,120, Aug. 5, 1905. Under Int. Conv., Aug. 5, 1904.

SEE Eng. Pat. 16,087 of 1905; this J., 1906, 78.—T. F. B.

Zinc Furnace. E. Dor-Delattre. Fr. Pat. 358,150, Sept. 29, 1905.

Aluminium Alloys; Annealing —— by heating to redness and tempering. C. Claessen. Fr. Pat. 358,028, Sept. 25, 1905.

THE alloys are brought to a red heat and gradually cooled down to temperatures varying between 485° C. and 540° C., according to the proportion of copper present, and also according to the purposes for which the alloys are to be used. They are then cooled rapidly by plunging them into fluid baths in the ordinary way.—J. H. C.

Aluminium; Soldering ——. N. Evangelidi. Fr. Pat. 358,166, Sept. 30, 1905.

IN order to make the solder adhere more firmly to the aluminium, it is first of all heated to a point above its melting-point and stirred for some time. The solder, which consists of tin, or an alloy of tin and lead, &c., may be directly applied to the aluminium whilst in the molten state; or else, it may be granulated or powdered after cooling, and sprinkled over the aluminium, which is then heated till the solder melts; or, finally, the two pieces to be joined may be separately covered with the prepared solder, and then joined by means of an ordinary solder.—A. G. L.

Aluminium or Alloys rich in aluminium; Soldering ——. L. Fries. Fr. Pat. 358,184, Sept. 30, 1905. Under Int. Conv., Oct. 5, 1904.

THE process consists in heating the parts to be soldered by means of a previously heated flux capable of dissolving aluminium oxide, *e.g.*, an alkali pyrosulphate. A solder consisting of aluminium or an alloy rich in aluminium, in the form of wire, foil or powder may be used; or else, the parts to be united may themselves serve as solder, being heated to their melting point by the hot flux and, if necessary, a blow-pipe flame.—A. G. L.

Metals; Aluminothermic preparation of ——. T. Goldschmidt. Fr. Pat. 358,071, Sept. 27, 1905.

THE lower oxides, *e.g.*, of chromium or manganese are mixed with 1 to 4 per cent. of chromic acid, or with a higher oxide of manganese before adding the 34 or 35 per cent. of finely granulated metallic aluminium, whereby the production of alloy is increased from 50 or 60 per cent. to 90 per cent.—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*A.*)—ELECTRO-CHEMISTRY.

(*Continued from page* 128.)

Nitrates from the Atmosphere; Electric production of ——. Silvanus P. Thompson. The Electrician, Feb. 9, 1906, 56, 666—670.

A DISCOURSE at the Royal Institution, on Feb. 2 (see also this J., 1906, 27).

Nitrites and Nitrates; Production of —— by electrolytic oxidation of Ammonia in presence of Cupric Hydroxide. W. Traube and A. Biltz. Ber. 39, 166—178, 1906.

IN continuation of previous work (this J., 1904, 987; 1905, 280) and in reply to Müller and Spitzer (this J. 1905, 279 and 550) the authors still maintain that cupric hydroxide has a favourable influence upon the oxidation of nitrites to nitrates. The effect is however, much less marked than upon the first stage of the process, the electrolytic production of nitrites from ammonia in solutions containing free alkali.

During the electrolysis a black deposit is observed on the anode which may possibly consist of a higher oxide of copper.—R. S. H.

Ozone; Production of —— by electrolysis of Alkali Fluorides. E. B. R. Prideaux. Faraday Soc. Proc., Jan. 30, 1906. [Advance Proof.]

THE author is unable to confirm the result of Gräfenberg (this J., 1903, 1242), who found that oxygen containing 3·48 per cent. of ozone could be obtained by electrolysis of aqueous hydrofluoric acid. With a current density of 100 ampères per sq. dcm. the percentage was 0·23. With saturated potassium fluoride solutions electrolysed at 0°C. in a glass U-tube coated internally with paraffin, and with a platinum anode, the largest yield was 0·65 per cent. of ozone with a current density of 10 ampères per sq. dcm. This yield is, however, affected by the duration of the experiment, and falls to 0·096 in 4 hours 20 minutes. With increased current density the yield is further reduced. The ozone was estimated by passing the gases through a solution of potassium iodide.—R. S. H.

ENGLISH PATENT.

[*Mercury Lamps*]. *Electrode material for vapour Electric Apparatus.* C. O. Bastian and G. Calvert, both of London. Eng. Pat. 2004A, Feb. 1, 1905.

THE light given by a mercury lamp is modified by adding 10 parts by volume of the liquid alloy of sodium and potassium in the proportion of their atomic weights to 90 parts by volume of mercury. Cadmium, strontium, lithium, &c., may also be added to the alloy.—A. G. L.

UNITED STATES PATENTS.

Cell; Electric ——. K. Tsukamoto, Tokyo, Japan. U.S. Pat. 809,647, Jan. 9, 1906.

IN an electric cell, the combination is claimed of an outer casing having located within it a carbon tube containing graphite, manganese dioxide, potassium chloride, potassium permanganate and ammonium chloride, and surrounded by a fibrous substance, such as blotting paper, which is bound around it. Between the inner surface of the shell and the fibrous coating around the carbon tube, is placed a mixture of ammonium chloride, potassium chloride, gypsum, mercuric chloride and dextrin.—B. N.

[*Electric*] *Cell; Asymmetric* ——. M. Büttner, Wilmersdorf-Berlin, Germany. U.S. Pat. 809,770, Jan. 9, 1906.

AN aluminium anode is used and a cathode of any metal, the electrolyte consisting of a solution of ammonium hydroxide and boric acid.—B. N.

Calcium Carbide; Apparatus [Electric Furnace] for the production of ——. E. F. Price, G. E. Cox and J. G. Marshall. Assignors to Union Carbide Co., all of of Niagara Falls, N.Y. U.S. Pat. 809,842, Jan. 9, 1906.

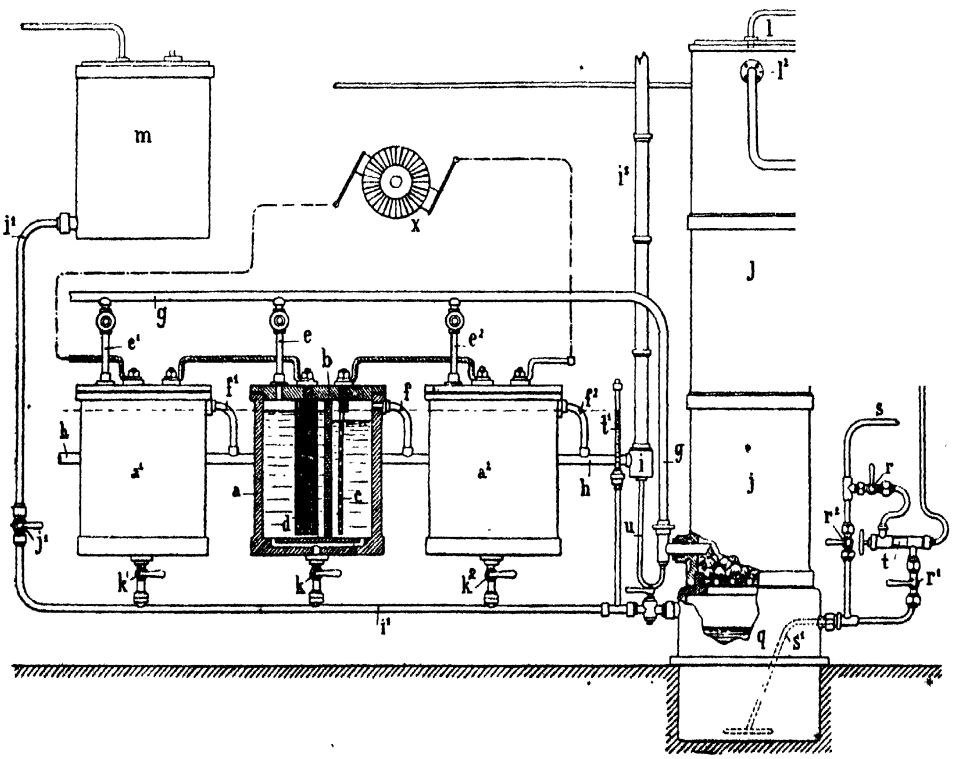
The electrodes of the electric furnace consist of spaced graphite rods of reduced cross-section, and a high current density is used in the electrodes in order to effect the reduction of the charge. A jacket, of relatively high resistance, surrounds the electrode rods, for the purpose of excluding oxidising gases from the rods and for supporting them against breakage. The furnace is provided with a feed-supply for lime and carbon, and there is also an arrangement for withdrawing heat from the ends of the electrodes remote from the zone of reduction.—B. N.

Hides; Process of [electrically] treating ——. F. B. Hinkson, Assignor to J. M. and J. J. Flannery. U.S. Pat. 810,144, Jan. 16, 1906. XIV., page 190.

French Patents.

Carbide of Silicon; Production of compact agglomerated —— by means of the Electric Furnace. A. J. V. Bouvier. Fr. Pat. 350,369, Dec. 5, 1904.

Agglomerated carbide of silicon is obtained by treating in the electric furnace a mixture of amorphous carbide of silicon, crystallised carbide of silicon, silica, coke-dust and sawdust. The agglomerated carbide is hard, resists the action of acids and high temperatures, and is good for insulating purposes.—B. N.



Electric Arcs; Process for effecting reactions between Gaseous substances by means of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 350,392, Dec. 12, 1904.

See Eng. Pat. 26,602 of 1904; this J., 1905, 1178.—T. F.B.

Nitrogen; Manufacture of compounds of —— from the air. Siemens et Halske A.-G. Fr. Pat. 358,171, Sept. 30, 1905. VII., page 180.

Chlorine; Manufacture of —— by electrolysis of Hydrochloric Acid. E. F. Côte and P. R. Pierron. Fr. Pat. 358,245, Oct. 3, 1905.

Pure chlorine is said to be obtain without loss of hydrochloric acid. a, a^1, a^2, are divided by diaphragms partments, metallic cathodes c and c connected to a suitable source solution of hydrochloric acid is which is of the same capacity ap of the electrolytic cells, by ope and one of the valves k, k^1, k^2, the cells may be ascertained by the escapes through f, f^1, f^2 into h, an bottle i into i^2. Some of the entrair gas condenses and collects in the sip runs into q, or it may be collected se The remainder of the acid is separate in absorption towers. The chlorine e, e^1, e^2 into g, and through the sto coke, over which a spray of wate falls. The aspirator l^1 draws off l^2. The water containing dissolved chloric acid collects in q, where it is liquid from the cells when the str diminished to 5 or 6 per cent. Steam r^2 being open and r and r^1 closed, boiling, and the chlorine is thus tower j and collected; r and r^1 are closed, when the steam acting through the weak acid liquid from q, through connection with the absorption tow acid. The acid liquid thus becomes chloric acid, and is delivered into m. about 250 litres capacity, and receiv ampères, do not require more than o

(B.)—ELECTRO-METAL

Iron; Anodic Corrosion of —— by and the passivity of iron. F. H schmidt. Z. Elektrochem., 1906,

The authors have submitted the ir

the electrolytic corrosion of water- and gas-mains to an experimental investigation. In most cases, danger is ascribed to the electric tramways, in which the overhead wires are positive whilst the rails are connected to the negative terminal of the generators at the central power station. This causes a marked anodic polarisation of the iron mains in the district near the power station, which is directly due to return currents leaking through the earth. The corrosion is peculiar, in that the outward appearance of the pipes is not much altered, but the iron is transformed into a soft mass which consists of ferrous phosphates and silicates mixed with particles of iron and carbon. From this appearance, however, one cannot conclude that the corrosion is electrolytic since many cases of ordinary corrosion have been found to give a similar result.

For studying this question, unpolarisable standard electrodes consisting of zinc plates surrounded by a paste of zinc sulphate have been employed. These are sunk in the ground at different points, and potential measurements between these various electrodes or between the electrodes and the rails or iron pipes enable the direction and magnitude of the earth current to be determined. For the more accurate estimation of the magnitude of the current, a special form of coulomb meter is recommended, but it has not been applied directly in the present work.

Before the effect of such currents can be foretold, it is necessary to know if the iron conduits are in the active or passive condition, since it is well known that under different circumstances iron can behave in these two ways. For the elucidation of this problem, the soils must be distinguished according to the constitution of the salt solutions which they have adsorbed. Of the more commonly occurring substances, alkalis and nitrates can be considered as favouring the passive state, chlorides and free carbonic acid as establishing the active condition necessary for corrosion to occur (see Mugdan, this J., 1903, 798). Of special importance is the behaviour of solutions of carbonates; even when these are slightly alkaline to start with, the passage of current increases the content of carbon dioxide in the layers immediately surrounding the anode, and the bicarbonate solution thus obtained is very favourable for corrosion, as it destroys the passive condition of the iron. Chlorides behave similarly. On account of the very dilute nature of the solutions, diffusion is unable to effect any marked diminution in this action.

The experimental work is very wide in its scope. Cases of corrosion under varying conditions of current and with different solutions have been examined in the laboratory. Measurements of the conductivity of soil and of solutions adsorbed by sand have also been carried out, and finally a series of direct measurements have been made in Strassburg in connection with the tramways in that city.

It is frequently found that the corrosion occurs only very locally upon the iron pipes, the difficulty of explaining this is dwelt upon, and the possibility of the attack being due to the abnormally high conductivity of the soil between the rails and mains at these points is put forward as the most likely explanation.

So far as the present investigation is able to throw light on this complicated question, the authors are inclined to believe that, except in such cases where the soil exhibits an abnormally high conductivity, no marked electrolytic corrosion is to be feared when the P.D. between the pipes and rails is below 1 volt. They ascribe this freedom from attack to the fact that under these conditions only minute currents can pass which would take many years to effect marked destruction, rather than to this potential being below a minimum necessary for electrolysis to occur.

—R. S. H.

Calcium; Electrolytic ——. L. Doermer. Ber., 1906, 39, 211—214.

When pieces of commercially prepared calcium, or the powdered metal are struck with a hammer upon an anvil, sharp explosions are noticed. These may perhaps be accounted for by reaction with the layer of rust, since if this is carefully removed, the effect is much less marked. The gas content of the metal is not marked; upon heating 50 c.c. of the powder, about 25 c.c. of hydrogen are obtained below a red heat, but this gas is reabsorbed at higher temperatures. Upon remelting the powdered metal, a more dense product is obtained, which is considerably more stable towards attack by air or water than the rods of the commercial metal.—R. S. H.

Copper silicide and the formation of Silicon soluble in hydrofluoric Acid. P. Lebeau. Comptes rend., 1906, 142, 154—157.

A mixture of equal parts of silicon and copper was fused in the electric furnace, and one portion was cooled suddenly by plunging into water, whilst another portion was allowed to cool very slowly. The products contained 43·5 and 41·9 per cent. of total silicon respectively. Determinations of the silicon existing in the state of combination with copper showed 12·8 per cent. in the case of the rapidly cooled alloy, but only 11·3 per cent. in the case of that cooled slowly. The analysis of copper-silicon alloys by the method previously employed (this J., 1905, 1508, also Comptes rend., 1905, 141, 889) always showed a deficit of 1·5—2·0 per cent. This was due to the presence of a modification of silicon soluble in hydrofluoric acid. The free silicon is extracted by long digestion with 10 per cent. caustic soda lye. The residue is oxidised by nitric acid, yielding a mixture of silica and silicon. Formerly this mixture was resolved by extracting the silica by hydrofluoric acid. Since, however, the silicon was partially soluble in that acid, the method now adopted consists in converting the mixture into potassium silicate and determining the silica in the product. The ratio of copper to combined silicon in these alloys always corresponds approximately to the formula $SiCu_4$. The micrographic examination of polished surfaces of the alloys, consisting of copper silicide and free silicon, after etching with potash, shows the differentiation between the combined and the free silicon. On etching with hot concentrated hydrofluoric acid, the distribution of the soluble variety of silicon can be ascertained. Copper silicide is best prepared by adding the calculated quantity of copper to a cupro-silicon rich in silicon. It melts at about 800° C., is very brittle and has a conchoidal fracture.—J. F. B.

Electroplating Apparatus. A. W. L'Hommedieu, Assignor to C. F. L'Hommedieu, both of Chicago, Ill. U.S. Pat. 809,309, Jan. 9, 1906.

A cylinder, mounted in an inclined position and closed at its lower end, is provided with a solution containing the metal to be deposited, and is arranged so that it may be rotated on its central axis. Means are provided for adjusting the inclination of the cylinder. The anodes are arranged around the inner surface of the cylinder, and one or more cathodes near to the axis, the electrodes being separated by a removable perforated cylinder of non-conducting material adapted to contain the material to be plated, the articles being supported by a metallic pan, placed near to the bottom of the outer cylinder and forming a part of the cathode.—B. N.

Metallic Coatings; Process for electrolytic production of lustrous —— upon metals. A. Classen, Aachen, Germany. U.S. Pat. 809,492, Jan. 9, 1906.

See Fr. Pat. 350,964 of 1905; this J., 1905, 806.—T. F. B.

Precious Metals; [Electrolytic] Apparatus for recovering ——. E. J. Garvin, Portland, Oreg., Assignor to Garvin Cyanide Extraction Co., Oregon. U.S. Pat. 809,939, Jan. 16, 1906.

The apparatus consists essentially of a main tank, a separa-

ting tank connected with the upper portion of the main tank, and an amalgamating tank connected with the separating tank and discharging into the main tank. The separating tank and amalgamating tank each have a number of metal partitions serving as anodes, and also a cathode partly immersed in a layer of mercury on the bottom of the tank. The mixture of pulverised ore and solvent in the main tank separates into two layers; the upper layer is conveyed to the separating tank where any ore is allowed to settle out, whilst the dissolved precious metal is recovered by a combined process of electrolysis and amalgamation. The lower layer from the main tank is mixed with the spent solvent from the separating tank, and the mixture is forced into the amalgamating tank; here the dissolved precious metal is separated by electrolysis and amalgamation, and the mixture of ore and solvent is discharged into the main tank.—A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 129.)

Arbutus Unedo Oil. G. Sani. Atti R. Accad. dei Lincei Roma, 1905, **14**, [2], 619—623. Chem. Centr., 1906, **1**, 373.

THE fruit of the *Arbutus Unedo* has been recently used at Perugia for the preparation of alcohol on a commercial scale. The author states that this process would prove still more remunerative if the oil contained in the distillation-residue of the fruits were extracted. The seeds of *Arbutus Unedo* contain 39·03 per cent. of a golden-yellow oil of sweet taste, having the sp. gr. 0·9208 at 15° C., and Zeiss refractometer reading at 25° C., 71 "degrees." The oil becomes turbid at 9° C.; at —23° C. it has the consistence of butter; at —27° C., it is solid. Its constants are:—saponification value, 208; iodine value, 147·86; Reichert-Wollny value, 0·861; Hehner value, 92·48; Maumené value (in Tortelli's apparatus, using olive oil as diluent; this J., 1904, 608), 103·5° C.; neutralisation value of liquid fatty acids, 198·26. The oil consists of the glycerides of palmitic, oleic, linolic and isolenolenic acids, the two latter predominating. Determinations by Hazura's method gave oleic acid, 3·43; linolic acid, 53·75; and isolinolenic acid, 24·33 per cent.—A. S.

Fats; Bacterial Decomposition of ——. O. Rahn. Centralbl. Bakteriol., 1905, **15**, 422. Chem.-Zeit., 1906, **30** [Rep.] 30.

A VIEW frequently expressed is that fats are only decomposed by micro-organisms that require nitrogenous food, but the author concludes that the decomposition must be effected by micro-organisms that require very little nitrogen. He prepared mixtures of mineral nutrient fluid with fat, and observed, under suitable conditions, marked decomposition of the fat. The micro-organisms isolated from the cultures were *Penicillium glaucum*, a *Penicillium* with brownish-yellow spores, a mould-fungus that coloured the fat red, a white and a gray mould fungus, a motile bacillus, *a*, producing a green fluorescent colouring matter, and a smaller non-motile bacillus, *b*. Pure cultivations of each of these were made and their action upon fat studied. It was found that the *penicillia*, had a pronounced action upon fats, attacking the glycerol and lower fatty acids, but not oleic acid. The white mould-fungus had a less energetic action; it oxidised volatile fatty acids, but did not attack oleic acid. The gray mould-fungus had but little action. The bacillus, *a*, had marked hydrolytic and oxidising powers; it decomposed oleic acid, but had no special action upon volatile fatty acids. Bacillus, *b*, had much less effect upon fats.—C. A. M.

ENGLISH PATENTS.

Fatty Substances; Apparatus for extracting —— from products containing them, by means of carbon tetrachloride. P. Bernard, Arras, France. Eng. Pat. 18,667, Sept. 15, 1905. Under Int. Conv., Dec. 24, 1904.

THE dried and powdered material is introduced into an extractor, the charging orifice of which is then hermetically sealed. Carbon tetrachloride is now introduced into the lower part of the vessel, expelling the air, which passes through a cooling coil where any vaporised solvent is condensed and returned to the reservoir. After sufficient extraction of the material a fresh quantity of carbon tetrachloride is introduced from the reservoir, and this drives before it the solvent charged with fat into an evaporating vessel, whence the evaporated tetrachloride is returned through a condenser to the reservoir.—C.A.M.

Soap; Manufacture of insoluble ——. P. Krebitz. Munich, Germany. Eng. Pat. 4092, Feb. 27, 1905.

A MIXTURE of the neutral fat with a metallic hydroxide, such as lime, is boiled and allowed to stand for several (five to ten) hours in a closed vessel. The resulting insoluble soap is ground, and the glycerin extracted by washing the mass with hot water, the final washings, poor in glycerin, being used in place of pure water in subsequent saponifications. The time required for saponification may be reduced to 30 minutes or one hour by the addition of, say, 5 per cent. of fatty acids or rosin.—C. A. M.

Detergents; Manufacture of ——. W. E. Heys, Watford, Herts. Eng. Pat. 17,999, Sept. 6, 1905.

CLAIM is made for the manufacture of detergents by mixing the oil or other saponifiable matter and a vegetable meal with sodium carbonate and treating the mixture with caustic soda lye, preferably containing some sodium bicarbonate. The resulting pulverulent mass is granulated by means of a sieve, and subsequently powdered in a disintegrator.—C. A. M.

FRENCH PATENT.

Washing Powders containing Alkali Peroxides; Process and apparatus for packing and preserving ——. Königswarter und Ebell. Fr. Pat. 358,167, Sept. 30, 1905.

SEE Eng. Pat. 19,809 of 1905; this J., 1906, 32.—T.F.B.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*Continued from page* 129.)

(*A.*)—PIGMENTS, PAINTS.

Aniline and its homologues; Black lakes from ——. S. Kirpitschnikoff. IV., page 173.

ENGLISH PATENT.

White Lead; Machine for the manufacture of ——, *and for use in similar processes.* J. Scott, Bombay, India. Eng. Pat. 23,915, Nov. 5, 1904.

THE apparatus comprises a revolving cylinder constructed in two parts, lined with tin or lead and provided with a hollow trunnion passage. Gases, air or steam are admitted to the cylinder through a passage in one of the trunnions on which it is mounted, or the gases may be introduced through a valve, used for charging and discharging the contents, and which, when closed, forms a flush face inside the cylinder, so that no material can lodge therein.—D. B.

German Patents.

Lakes [from Azo Dyestuffs]; Process of preparing colour ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 160,172, May 28, 1903.

Lakes are prepared in the usual manner from the dyestuffs obtained by combining a diazonium compound with 1.8-alkyloxynaphthol-3.6-disulphonic acid. They are stated to be similar in shade to Eosin lakes, but faster to light. The lake from 2-naphthylamine-6.8-disulphonic acid is bluish-red, that from *o*-chloraniline yellowish-red, and that from *p*-toluidine-*o*-sulphonic acid red.—T. F. B.

Dyestuff for Lakes; Process for preparing a monoazo ——. Meister, Lucius und Brüning. Ger. Pat. 163,055, Aug. 24, 1904. IV., page 176.

(C.)—INDIA-RUBBER, Etc.

Rubber; Resin-content of some different kinds of ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 394—395.

Thin sheets (0·2 mm. thick) of the rubber, prepared by masticating the sample previously dried *in vacuo* over calcium chloride, were extracted with acetone in a Soxhlet apparatus. The following results were obtained:—

Trade name and source of rubber.	Resin.
	Per cent.
Parà fine; *Hevea brasiliensis* (America)	1·44
Ecuador scraps; *Castilloa elastica* (America)	3·12
Santos Mattogrosso Mangabeira; *Hancornia speciosa* (America)	12·18
Guatemala sandy; *Castilloa elastica* (America)	9·6
Red Adeli balls; *Landolphia owariensis* (Africa)	12·23
Mozambique balls; *Landolphia owariensis* (Africa)	8·62
Large ditto	11·23
Fine Mozambique spindles; *Landolphia* (Africa)	6·80
Fine Red Massai balls; *Landolphia* (Africa)	4·40
Gambia balls; *Landolphia senegalensis* (Africa)	3·40
South Cameroon balls; *Landolphia* (Africa)	5·99
Lewa rubber; *Manihot glaziovii* (Africa)	6·81
Madagascar low; *Landolphia* (Africa)	3·39
Madagascar niggers; *Landolphia* (Africa)	3·94
Mozambique unripe; *Landolphia* (Africa)	6·68
Soudan twists (Africa)	7·99
Borneo rubber; *Ficus elastica* (Asia)	4·76
Fine Ceylon Parà; *Hevea brasiliensis* (Asia)	2·26
Fine Parà rubber	0·57

The method of drying the rubber exercises a considerable influence upon the determination of the resin-content by acetone-extraction. Whereas a sample of fine Parà dried *in vacuo* over calcium chloride, yielded to acetone 1·44 per cent., another sample of the same rubber dried at 80° C. in an oven yielded 6·83 per cent. Samples of Ecuador scraps, similarly treated, yielded 3·12 per cent. and 30·2 per cent. respectively. The action of the resin at the elevated temperature appears to be to form a rubber "solution" ("Kautschukharzquellung") soluble in acetone.—E. W. L.

Rubber vulcanised by heat; Influence of sulphur-content on the tensile strength of ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 394.

A good commercial Parà rubber, containing (washed and dried) 6·27 per cent. of resins, and 0·27 per cent. of ash, was masticated with quantities of milk of sulphur ranging from 5 to 40 per cent. of sulphur on the weight of the rubber. The mixtures were vulcanised at 145° C. under a pressure of 4—5 atmospheres for 50 minutes, in cylindrical glass moulds, in an autoclave. After three hours the rubber cylinders were broken in a dynamometer. The breaking strains and extensions (of a cylinder 2 cm. long and 17·5 mm. in diameter) are given in the following table, and indicate that under the conditions specified the maximum strength is obtained with a rubber vulcanised with about 20 per cent. of sulphur:—

Sulphur added to raw rubber.	Breaking strain.	Elongation.	Sulphur added to raw rubber.	Breaking strain.	Elongation.
Per cent	kilos.	cm.	Per cent.	kilos.	cm.
5	3·25	5·5	25	14·25	9·6
10	9·5	7·5	30	14·0	9·2
15	13·0	9·7	35	13·9	9·0
20	14·5	9·7	40	13·7	9·0

Caoutchouc; Torrey's method of determining pure ——. R. Ditmar. XXIII., page 200.

English Patent.

Rubber; Extraction of pure raw —— *from rubber plants.* K. von Stechow, Wiesbaden, Germany. Eng. Pat. 12,859, June 21, 1905.

See Fr. Pat. 355,611 of 1905; this J., 1905, 1245.—T.F.B.

French Patent.

Caoutchouc; Process of making aqueous Solutions of —— *and of regenerating caoutchouc.* P. Alexander. Fr. Pat. 358,018, Sept. 25, 1905.

See Eng. Pat. 14,681 of 1905; this J., 1905, 1244.—T.F.B.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 130.)

Leather Industries; Yearly report (1905) *of the German Research Institute for* ——. J. Paessler.

The results of a large number of analyses of tanning materials, showing the variable percentages of tannins they contained, are given in the following table:—

Tanning material.	Oak-bark.	Pine-bark.	Wattle-bark.	Mangrove-bark.	Mallet-bark.	Valonia.
Number of analyses	82	110	25	32	49	28
Tannins	Per cent. 10·3 [12·6]	Per cent. 12·7 [17·2]	Per cent. 34·4 [42·0]	Per cent. 32·3 [48·6]	Per cent. 44·8 [55·6]	Per cent. 31·4 [36·4]
Sol. non-tannins	[6·4] 6·6	[7·1] 9·6	[16·9] 9·9	[19·6] 11·4	[36·7] 7·8	[24·2] 11·7
Insoluble	72·7	66·6	44·8	43·8	33·7	44·7
Water	10·4	11·1	10·9	12·5	13·7	12·2

Tanning material.	Valonia-beard.	Myrobalans.	Myrobalans (stone freed).	Divi-divi.	Quebracho-wood.	Sumach.
Number of analyses	85	13	4	7	23	50
Tannins	Per cent. 42·1 [51·3]	Per cent. 30·8 [42·6]	Per cent. 52·0 [54·7]	Per cent. 44·6 [49·6]	Per cent. 20·9 [24·1]	Per cent. 26·8 [32·8]
Sol. non-tannins	[32·1] 14·0	[31·8] 14·6	[46·7] 16·2	[40·9] 18·5	[15·0] 1·4	[18·0] 16·2
Insoluble	31·8	38·7	17·8	27·3	63·1	45·0
Water	12·1	9·9	12·0	9·6	13·8	9·0

Note.—The figures given in the above tables relate to the average values, but, in the case of the tannins, the maximum and minimum values also are given in brackets.

—F. K. K.

Chromium Compounds; Poisonous nature of —— and their effect in chrome leather manufacture. H. Becker. Collegium, 1906, 35—36, 37—44.

An exhaustive investigation upon this subject was made and its results were communicated to the German section of the International Assoc. of Leather Trades Chemists (I.A.L.T.C.), at their last meeting in Frankfort on the Maine. The fact that chromic acid and its salts are poisonous is well known, but only a single case of serious blood poisoning in the chrome leather industry could be traced by the author. Now and then, when acting contrary to instructions, inexperienced workmen suffer from sore fingers; frequently little care is taken of these sores to begin with, and, once neglected, they take a long time to heal. The workmen should be supplied with rubber gloves, and their hands should be occasionally examined. They should rub vaseline on to their hands and arms, and every small injury should be properly dressed, a waterproof bandage being used. The workmen should be informed of the poisonous nature of chromic acid and its salts, and respirators should be supplied to those who weigh out the bichromate.

Chromic oxide is non-poisonous, and no danger whatever can, therefore, arise to the public from using chrome-tanned leathers, nor to workmen employed in factories which employ the "one-bath" method for tanning skins or hides.—F. K. K.

English Patents.

Tanning leather and skins; Process of ——. C. Baron, Marseilles, France, and J. Aubert, Genes, Italy. Eng. Pat. 17,551, Aug. 30, 1905. Under Int Conv., Oct. 14, 1904.

See Fr. Pat. 347,097 of 1904; this J., 1905, 284.—T. F. B.

Films, sheets and cords; Producing non-absorbent ——. F. E. Blaisdell, London. Eng. Pat. 1398, Jan. 24, 1905.

Films of gold-beater's skin are coated with a solution of a gelatinous or albuminous solution containing potassium bichromate. The coated film is then exposed to light, and the coating is rendered tough and non-absorbent. If desired, the skin may first be impregnated with chromic acid and then coated with the gelatinous substance. Cords of gut, parchments and similar materials may also be treated with potassium bichromate or chromic acid.—J. F. B.

United States Patent.

Hides; Process of [electrically] treating ——. F. B. Hinkson, Newcastle, Pa., Assignor to J. M. and J. J. Flannery, Pittsburg, Pa. U.S. Pat. 810,144, Jan. 16, 1906.

The hides are suspended in a bath, each hide being disposed between a pair of electrodes through which an electric current is passed. The current passes transversely through the hides, and its direction is reversed at suitable intervals (see U.S. Pat. 807,930 of 1905; this J., 1906, 83).—A. S.

French Patent.

Horn Substitute; Manufacture of a ——. H. Schwarzberg. Fr. Pat. 358,172, Sept. 30, 1905.

Fifty parts of casein are dissolved in an aqueous solution of borax; 50 parts of starch are then added, sufficient water being used to make the whole into a paste. Twenty-five parts of gelatin, 0·25 part of glycerin, and 7 to 10 parts of melted paraffin are now mixed with the paste together with a quantity of α-naphtholsulphonic acid equivalent to from 1 to 5 per cent. of the whole. The product is allowed to dry in the form of thin films, then completely dried by treating with alcohol and finally rendered waterproof by subjecting it to the action of aluminium acetate or hexamethylenetetramine.—W. P. S.

XVI.—SUGAR, STARCH, GUM, Etc.

(*Continued from page* 130.)

Sugar Juices; Preservation of —— by mercuric chloride. L. Ehrmann. Bull. Assoc. Chim. Sucr. Dist., 1905, 23, 634.

Samples of cane juice which cannot be analysed on the spot have often to be sent by post, and it is usual in such cases to add 1 part of mercuric chloride per 1000 of juice to prevent changes due to fermentation. The powdered salt, however, tends to remain undissolved unless the sample is well shaken, and the preparation of the bottles is tedious. A few c.c. of a concentrated alcoholic solution of the mercuric salt are preferably added, the liquids evenly mixed by merely turning the bottle around, and the alcohol finally expelled by exposure to the sun or by heating.—L. J. de W.

Cane and other Molasses; Elimination of the invert sugar in —— by fermentation. H. and L. Pellet and Pairault. Bull. Assoc. Chim. Sucr. Dist., 1905, 23, 639—647.

It is now established in a general way that yeasts (and moulds) which secrete only zymase and no sucrase (invertase) are incapable of inverting sucrose and can act only on invert sugar or reducing sugars.

One of the authors (Pairault) found a yeast which in five days fermented the whole of the reducing sugars in a sample of molasses in Martinique, but left the sucrose practically untouched. The experiments were repeated at the Pasteur Institute, Lille, with molasses and yeast from Martinique, the yeast which had been preserved dormant having been resuscitated in invert sugar agar-agar solution. The results, as a whole, show that a yeast not containing invertase has been isolated. Several well-defined yeasts of the kind are known; but the present organism has not been characterised.—L. J. de W.

Apiose. E. Vongerichten and F. Müller. Ber., 1906, 39, 235—240.

Apiose is a pentose sugar having the constitutional formula $(CH_2OH)_2C.OH.CHOH.CHO$, existing in conjunction with dextrose in the glucoside apiin which is obtained from parsley seed (see this J., 1900, 1139; 1901, 1034, and 1902, 596). It is now found that the green portions of the parsley plant contain, besides apiin, a considerable proportion of another glucoside, hydroxy-apiin methyl ether, which also yields apiose on hydrolysis. Apiose, when oxidised by nitric acid, yields first apionic acid, and finally a dicarboxylic acid which is probably hydroxymethyltartaric acid. Apiose reduces Fehling's solution, the ratio of the cupric-reducing power of apiose to that of dextrose being 1 : 0·74.—J. F. B.

Formaldehyde; Production of Sugar from ——. H. and A. Euler. Ber., 1906, 39, 39—45 (see also this J., 1905, 902).

The authors show that, with a suitable concentration of formaldehyde, the latter can be condensed to sugar by any soluble base; with feebly condensing bases, it is only necessary for the concentration of the formaldehyde to be sufficiently small compared with that of the base. When sodium carbonate is employed as base, the concentration of the formaldehyde when sugar is first formed, depends directly on the initial concentrations of the aldehyde and alkali, as the formation of sugar only occurs after a certain amount of the aldehyde has been converted into formate and methyl alcohol. The concentration of sodium carbonate most suitable for the sugar-condensation is somewhat less than one-half that of the aldehyde; increase of the concentration favours the formation of formate, especially in concentrated solutions. It is found that glycollic aldehyde is formed as an intermediate stage between formaldehyde and sugar. The following figures, all referring to grm.-mols. of formaldehyde, illustrate the course followed by a condensation.

	At first.	After.		
		10 hrs.	13 hrs.	14 hrs.
Formaldehyde	0·67	0·47	0·11	—
Formic acid + methyl alcohol	—	0·04	0·06	0·065
Glycollic aldehyde	—	0·24	0·07	0·07
Higher sugars—pentoses (by diff.)	—	0·136	0·43	0·535

—T. H. P.

i-Arabinoketose from Formaldehyde; Formation of ——. H. and A. Euler. Ber., 1906, **39**, 45—51. (Compare preceding abstract.)

When formaldehyde is condensed by means of calcium carbonate, less formate and better defined sugars are obtained than when an alkaline solution is employed. From the products of such a condensation, the authors have prepared:—(1) *i*-arabinophenylosazone, the corresponding sugar being, not *i*-arabinose, but *i*-arabinoketose, and (2) a small quantity of the phenylosazone of a hexose. If the condensation is interrupted before one-half of the formaldehyde has been attacked, the solution is found to contain glycollic aldehyde.—T. H. P.

Caramelisation of Sugar; Function of formaldehyde in the ——. A. Trillat. Bull. Assoc. Chim. Sucr. Dist., 1905, **23**, 652—655.

The formation of formic aldehyde during the heating of sugar (this J., 1905, 901) may serve to throw light on the phenomenon of caramelisation. Several caramels examined by the author contained from 0·005 to 0·325 per cent. of formaldehyde. In sugar heated to 125° C. i.e., before caramelisation occurs, the presence of formaldehyde could be detected. The conclusion is that caramel, or sugar which has commenced to caramelise, contains more or less formaldehyde which influences its reducing properties and its fermentability. This formation of aldehyde explains, at least partially, the variations in the reducing power of massecuites, and the destruction of sugar therein by heat. It may also explain the fact that sugar canes, which have taken fire and been partially burnt, never ferment, owing to the antiseptic property of formaldehyde. Besides the free formaldehyde found in sugar caramel, a considerable proportion will have become polymerised, furnishing products similar to methylenitan or to formose, which portion no longer gives the reactions of formaldehyde. It is of interest to note that on heating a solution of formaldehyde to which lime, soda or potash has been added, a brown sticky mass is obtained, having the odour of sugar caramel and the bitter taste of this product.—L. Potash; Apparatus for extracting crude —— *[from waste waters of Beet Sugar Factories].* G. W. Henry and F. W. Beale, Denver, Colo. U.S. Pat. 803,058, Oct. 31, 1905.

The invention consists essentially in apparatus for evaporating the water from the wash-liquids, which contain most of the potash in the beet, by means of the waste heat from the boiler-grates of the refinery. For this purpose the wash-waters are run into a tank, whence they pass into a shallow metal trough which is built into the whole of the top of a long horizontal flue, through which the waste gases are made to pass on their way from the boiler-grates to the smoke-stack. An outlet from this trough is controlled by a vertically sliding gate, by means of which the amount of liquid in the trough may be suited to the quantity of hot gases passing through the flues. The overflow from the trough passes into a basin from which it may be again returned to the main tank and, finally, to the evaporating trough.—A. G. L.

French Patents.

Separation of Solids (Beetroot Slices) held in suspension in liquids; Apparatus for ——. L. von May, Fr. Pat. 358,082, Sept. 27, 1905.

The liquid carrying the solids in suspension is caused to flow over an inclined perforated plate into a perforated trough. The liquid drains through the perforations, and the solids are removed from the trough by a rotating S-shaped brush, and are swept on to a plate from which they slide into a perforated conveyor trough. The conveyor carries the solids forward, at the same time squeezing out the remainder of the liquid, and delivers them to an elevator.—W. H. C.

Beetroots; Separation of Juice from ——. M. Weinrich. Fr. Pat. 358,156, Sept. 29, 1905.

The fresh beets are fed from a hopper against a rasping-cylinder by means of a reciprocating piston. A stream of dilute milk of lime, or lime dissolved in weak juice, is allowed to fall on the rasping cylinder by which it is thoroughly mixed with the beet pulp. The mixture of pulp and milk of lime then passes through a series of vessels in which it is stirred by paddles, and is heated by means of steam to a temperature of 70°—75° C. The pulp is then passed through pressing machinery which removes the juice. The mares may subsequently be mixed with water and subjected to a second pressing, the dilute juice from which may be used for dissolving the lime.—J. F. B.

Combustible or artificial coal composed of House Refuse and Nightsoil, ground together with Coal or Charcoal Dust and an Agglomerant composed of Water, Molasses and Glucose. J. P. Renenaux and A. Perrier. Fr. Pat. 358,200, Oct. 2, 1905. II., page 170.

Starches; Manufacture of Rice and Maize ——. J. Jean et Cie. Fr. Pat. 350,370, Dec. 5, 1904.

Rice or purified maize is treated with an equal weight of a 2 per cent. solution of phosphoric acid, and the mixture is thoroughly stirred until it becomes homogeneous and the gluten is dissolved. It is then diluted with four times its weight of water, and the dissolved gluten is separated from the starch by washing. The acid solution is neutralised by lime and the phosphoric acid is recovered. Hydrochloric acid may be used instead of phosphoric acid.

(*Continued from page* 132.)

Enzyme Action. II. H. P. Barendrecht. Z. physik. Chem., 1906, **54**, 367—375. (See this J., 1904, 945.)

The author has extended his investigation to the hydrolysis of lactose by the lactase prepared from a pure culture of *Saccharomyces Kefir.* The reaction was similar to that of the inversion of sucrose by invertase; that is, with a given quantity of the enzyme the amount of decomposition was proportional to the concentration of the sugar solution, only when this concentration was very low. As the concentration increased, the amount of inversion relatively diminished, finally becoming constant. The author states that this behaviour appears to represent the fundamental law of enzyme action. The

retarding effect of the reaction products on the decomposition of lactose by lactase is greater than in the inversion of sucrose by invertase. Moreover, of the two hexoses produced, galactose retards the reaction nearly twice as much as dextrose does, whereas in the inversion of sucrose the retarding effects of dextrose and levulose are identical. The author seeks to explain this difference by means of his radiation hypothesis of enzyme action (this J., 1901, 945). The enzyme lactase may be regarded as consisting of galactose and dextrose in a "living radiating condition" combined with albuminoid substances. Both the galactose and dextrose radiations are capable of decomposing lactose. In the lactose molecule, however, the dextrose portion is present in a less altered or modified condition than the galactose portion, and hence the dextrose radiation will be absorbed to a smaller extent (by the galactose portion of the lactose molecule) than the galactose radiation (by the dextrose portion of the molecule). Thus, in the hydrolysis of lactose by lactase, the dextrose radiation is the more active agent, and hence the reaction will be retarded to a greater degree by added galactose than by dextrose, whilst foreign hexoses, which absorb equally both the dextrose and galactose radiations, should have a retarding effect as great as galactose and dextrose together. This latter conclusion was confirmed experimentally.—A. S.

Diastase; Influence of the reaction of the medium on the activity of ——, and the products of saccharification of Starch. L. Maquenne and E. Roux. Comptes rend., 1906, **142**, 124—129.

All starches and malt-infusions have an alkaline reaction towards methyl orange, the degree of alkalinity varying in different samples. As a general rule starch pastes neutralised exactly to methyl orange by the addition of N/10 sulphuric acid are saccharified more rapidly than ordinary pastes. If the addition of acid be extended so as to diminish the alkalinity of the mixed medium, starch paste and malt infusion, the rate of saccharification increases up to a maximum point, and then rapidly decreases as the point of exact neutrality is approached. As soon as the neutral point is passed and the total mixed medium acquires an acid reaction, saccharification ceases. A distinct alkaline reaction to methyl-orange is, therefore, essential to the saccharification of starch by malt. By a series of tests with starches of various origins the authors have found that the most rapid saccharification is obtained by first neutralising the starch paste to methyl orange and then adding to the malt infusion a quantity of acid equal to about 33·66 per cent. of the quantity required to neutralise it completely. The neutralisation of the medium to this extent not only intensifies the activity of the diastase but also increases the proportion of maltose in the products of saccharification. The proportion of the original starch which is converted into maltose is raised from 75—82·5 per cent., in the case of the ordinary media, to 86—92 per cent. in the case of the neutralised media. The conclusions formulated in this J., 1905, 630, must, therefore, be modified slightly in a quantitative sense. It must be admitted that the starches contain, in their ordinary condition as pastes, not 80 per cent. of amylocellulose ["amylose"] but about 90 per cent., in presence of about 10 per cent. of amylopectin, unless this latter body is capable of being resolved by a specially active diastase with the separation of an amylose residue.
—J. F. B.

Diastase; Influence of the reaction of the medium on the activity of ——. A. Fernbach. Comptes rend., 1906, **142**, 285—286.

Referring to the observation of Maquenne and Roux (see preceding abstract) on the influence of the degree of alkalinity of the medium towards methyl orange upon the velocity and the extent of the conversion of starch-paste by malt extract, the author points out that such media contain both primary and secondary phosphates, the latter being very inimical to diastatic activity. The addition of acid to the point of neutrality to methyl orange converts the secondary phosphates into primary phosphates and neutralises the inhibitive influence of the former, thus establishing a condition which is most favourable to diastatic action (see this J., 1900, 260). In the absence of secondary phosphates the addition of the least trace of acid has a retarding effect. The influence of the phosphates is not confined to diastatic actions; the same observation has been made with regard to the proteolytic action of malt enzymes (this J., 1900, 916), and also in the case of the coagulation of starch pastes by malt extract.—J. F. B.

Formic Acid; Inhibitive action of —— on various fungi. W. Henneberg. Z. Spiritusind., 1906, **29**, 34—35.

The author has tested the action of formic acid at various concentrations on distillery yeasts in grain and potato mashes. Observations were made with pure cultures of yeast and other organisms, with cultures under industrial conditions, and with cultures purposely infected by various harmful bacteria and fungi. The proportions of formic acid necessary to prevent the development of the different organisms varied according to the conditions, *e.g.*, the quantity sown and whether present in pure cultures or as mixtures. Under industrial conditions with infected yeasts, proportions of 0·17—0·25 per cent. of formic acid sufficed to prevent the development of all the organisms other than the culture yeast, which proved to be the most resistant. The infecting organisms, however, were not killed, but were capable of developing when transferred to ordinary wort. The resistance of the culture yeasts to the presence of formic acid could certainly be increased by acclimatisation, so that formic acid is quite suitable for use as an antiseptic in distilleries and yeast factories.
—J. F. B.

Sulphurous Acid; Mechanism of the acclimatisation of yeasts to ——. G. Gimel. Bull. Assoc. Chim. Sucr. Dist., 1905, **23**, 669—672.

It is generally said that the acclimatisation of yeasts to sulphurous acid is illusory, but the author finds that it is quite real in the presence of unstable mineral matter or an easily decomposable salt. The adaptation develops the protoplasmic activity leading to the secretion of an oxidising substance. The chief characteristic of the acclimatised yeast is the greater quantity of sulphates to be found in the ash.—L. J. de W.

Mucor javanicus; Fermentation by ——. C. Wehmer. Centr. Bakt., II., 1905, **15**, 8. Z. ges. Brauw., 1906, **29**, 53.

Mucor javanicus has a much more energetic fermentative action than *Mucor racemosus* and readily attacks strong wort of 15—16 per cent. Balling (21·6—25·6 lb. per barrel). The amount of alcohol produced lies usually between 4 and 5 per cent., rising in some cases to over 6 per cent. In the decomposition of sugar by this mould, small quantities of non-volatile acids are also formed. This alcoholic fermentation is not a consequence of lack of air, and occurs when the latter has free access to the solution, so that it is quite immaterial whether the fungus grows as mycelium or in the yeast form, the latter being obtained more readily and more abundantly than with *Mucor racemosus*. In presence of oxygen, the alcohol formed appears to be scarcely attacked by the mould. Restriction of the access of air to the solution causes the greatest diminution in the mould-growth, the decomposition of sugar being influenced to a less, and the production of alcohol to a still less, extent.—T. H. P.

Sulphured Hops; How much sulphurous acid do —— give up to Beer Wort? Wiegmann. Allgem. Brauer.- u. Hopfenzeitung, 1905, **45**, 115. Z. ges. Brauw., 1906, **29**, 52—53.

The author finds that hops contain from 0·088 to 0·320 per cent. of sulphur dioxide and that 1 litre of hopped wort contains from 2·3 to 5·5 mgrms. of sulphur dioxide, according to the extent of the sulphuring. Hops originally unsulphured also show the presence of as much as 0·088 per cent. of sulphur dioxide, this being formed during the course of the analysis from a sulphur compound in the hops. Assuming that 100 litres of wort produce about 75 litres of finished beer, the quantity of sulphur dioxide in the latter which can be attributed to sulphured hops

will, under the most unfavourable conditions, amount to from 3 to 7·4 mgrms. per litre (0·2—0·5 gr. per gall.). This small proportion may be neglected, since it has been shown that certain yeasts produce much larger amounts of sulphur dioxide than this, especially in presence of sulphates and amides.—T. H. P.

Wort Boiling. M. J. Cannon and W. Fyffe. J. Inst. Brewing, 1906, 12, 39—55.

THE authors discuss the differences between the two systems of boiling the wort, by steam and by direct fire. According to experiments carried out with portions of the same worts boiled by the two systems, it would appear that the chief differences manifest themselves as differences in the stability of the beer, *i.e.*, the permanence of brightness, flavour and character over lengthy periods. It was found that a very fair measure of the stability was obtained by boiling the beer in a flask, making it up to the original volume and observing the amount and character of the albuminous deposit which separated on standing. Those beers which threw a heavy flocculent deposit invariably showed a tendency to haziness and alteration in flavour at an early date, whilst those in which a very slight precipitate was formed remained free from these defects for a considerable period. The experimental parallel boilings were made on the one hand in a gas-heated copper and on the other hand in a jacketed open pan heated by steam at pressures of 16—45 lb., whilst in another series a closed pan, in which the wort was boiled under a pressure of 4 lb. per sq. in. was employed. In practically all cases the worts boiled by direct fire gave beers which cleared earlier and remained bright for longer periods than the beers from the worts boiled by steam, and the inferiority of the latter was greater the lower the steam pressure employed. It is certain that the superiority of the beers boiled over a fire was not due to a higher temperature of the bulk of the wort during ebullition, since the actual temperature of the wort was frequently higher in the case of the steam boiling, particularly in the closed copper. The difference is really attributable to the vastly higher temperature of the heating surfaces in boiling by direct fire, whereby the wort is momentarily superheated whilst in contact with the bottom of the pan, and a "cooking" action takes place, as distinguished from mere ebullition. This difference is illustrated chemically by a series of analyses described in the paper, determinations being made of the "albumins," "peptones" and "amides" in the different worts. It was found that the boiling by direct fire reduced the proportions of "albumins," both coagulable and uncoagulable, whilst increasing the proportions of "peptones" in the wort. Analyses of beers prepared from the worts boiled by fire and steam respectively also showed lower proportions of "albumins" and "peptones" and higher proportions of "amides" in the products boiled by direct fire. Hence the operation known as "cooking," which is produced by boiling over a fire results in an increased coagulation and a degradation of the albuminoids remaining in solution in the wort, with an accumulation of the lower, unprecipitable, and, therefore, stable forms at the expense of the higher colloidal forms, which are liable to form deposits and hazes on storage.—J. F. B.

Cane- and other Molasses; Elimination of the invert sugar in —— by fermentation. H. & L. Pellet and Pairault. XVI., page 190.

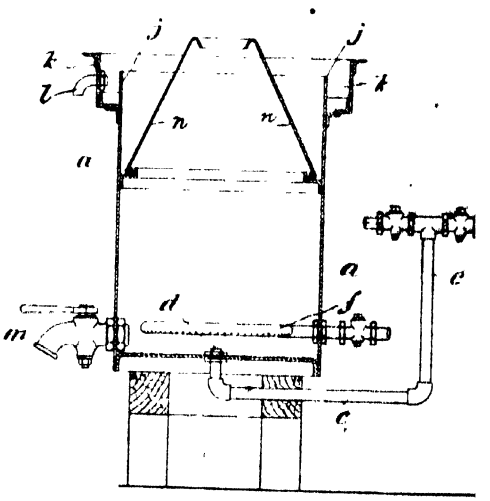
Alcohol; Manufacturing tax on —— in France. Bd. of Trade J., Feb. 1, 1906.

A FRENCH presidential decree fixes the rate of the manufacturing tax on alcohol, and products with an alcoholic base, from the 1st January, 1906, at 1 fr. 62 cts. per hectol. of pure alcohol. [T.R.]

Spirits and Beer; Production of —— in United Sta
Bd. of Trade J., Feb. 8, 1906.



IN the annual report for the year ended 30th June, 19
of the Secretary of the United States Treasury, it
stated that the total production of distilled spirits in
United States, exclusive of fruit brandies, was 147, 810,
taxable galls., against 134,311,952 galls. in 1903—
an increase of 13,498,842 galls. The production
fruit brandies increased by 255,322 galls. During
fiscal year 1904—5, 1772 distilleries of all kinds w
in operation, a decrease of 400 as compared with the p
ceding year. The production of beer was 49,522,0
barrels, an increase of 1,256,861 barrels. [T.R.]

ENGLISH PATENTS.

Worts, Beers, Stout and the like; Apparatus for fermentin maturing and storing ——. T. Crossman, Oldha Lancs., and O. Selg, New York. Eng. Pat. 837 April 19, 1905.

THE apparatus consists of an open or closed tank havi a conical lower portion, at the bottom of which is situat a sludge chamber, connected with the tank by a slui valve. Within the tank is placed a skimming funn supported at the surface of the liquid by floats and co nected with the outside by a flexible tube. An attempe tor is also placed in the tank, having pipes with a diamon shaped section so as to prevent the settling of any sludg on the pipes. The preliminary sludge which rises at th beginning of the fermentation is withdrawn by the skimme the latter is then washed out and the top yeast removec The heavy sludge sinks and is collected in the sludge vesse Finally the sluice valve is closed and the clear beer i withdrawn through a racking cock in the conical part of th tank.—J. F. B.

Pulp [for Beer Filtration], Apparatus for cleansin and sterilising ——. H. J. West and Co., and L. Chew London. Eng. Pat. 12,765, June 20, 1905.

THE pulp is washed in a vessel containing water by submitting it to the combined action of jets of water and of air introduced under pressure at the lower part of the vessel. The fibres are thereby thoroughly subdivided and carried upwards against the inner sloping surface of a perforated cone from which they fall down again for further treatment. In the figure, *a* is the washing vessel containing the pulp; the pipe *c*, and nozzle *d*, serve for the introduction of the water or steam, whilst the compressed air enters through the perforated ring *f*; *n* is the perforated inverted cone against which the pulp is projected, whilst the foul water passes into the trough *k*, over the weir *j*, and flows out through the pipe *l*. The pulp is sterilised by means of steam introduced through the nozzle *d*.—J. F. B.

Beer; Processes for Pasteurising —— and apparatus for use therein. K. H. Loew, Lakewood, U.S.A. Eng. Pat. 25,495, Dec. 7, 1905.

See U.S. Pat. 808,668 of 1906; this J., 1906, 131.—T.F.B.

Acetification; Apparatus for automatic ——. L. Royer, Paris. Eng. Pat. 24,245, Nov. 24, 1905.

The apparatus consists of a high cylinder divided by horizontal partitions into a number of separate compartments of equal volume. Each compartment is filled with beech chips and is provided with a siphon discharging into the next lower compartment. All the compartments are fitted with air-outlet valves leading to a condenser, and with inlet valves for the admission of sterilised air when the siphons act. The liquid is admitted to the apparatus from a tank through a tap regulated to pass in three hours a volume exactly equal to the capacity of the individual compartments. This tap delivers the liquid into a tipping vessel provided with a siphon, so that every three hours a charge of liquid is allowed to pass into the apparatus. The lowest compartment is provided with an overflow through which the acetified liquid flows into barrels, &c. —W. P. S.

United States Patents.

Beer; Method of Pasteurising ——. H. Gronwald, Berlin. U.S. Pat. 810,745, Jan. 23, 1906.

French Patents.

Beer; Manufacture of —— by Fermentation at relatively high temperatures. J. F. Wittemann. Fr. Pat. 358,228, Oct. 3, 1905.

Fermentation is started at a temperature of about 10° C., and the fermenting wort is not cooled in the usual way during the process of primary fermentation, so that the final temperature may be as high as 20°—25° C. The carbon dioxide and the volatile aromatic principles of the beer, which escape during fermentation at so high a temperature, are collected and compressed in storage vessels, and are subsequently returned to the beer under pressure after clarification. At the high temperature employed, the fermentation of the maltose is practically complete after the stage of primary fermentation, and the beer can be chilled to a temperature of 1° C. for rapid clarification without after-fermentation. The gas employed for saturating the beer may be enriched in aroma by passing it over dry hops.—J. F. B.

Musts, Wines and other Acid Liquids; Process for determining the total acidity of ——. P. P. A. Andrieu. Fr. Pat. 357,957, July 29, 1905. XXIII., page 202.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 132.)

(*A.*)—FOODS.

Wheat Flour; Bleaching of ——. E. Fleurent. Comptes rend., 1906, **142**, 180—182.

In the bleaching of flour only those processes have an industrial value which are based on the utilisation of nitrogen peroxide produced either chemically or by the action of electricity on air. Pure oxygen, when ozonised, has no action on the colour of the flour, and imparts a disagreeable odour to the product. Calculated as nitrogen peroxide, the quantity of bleaching agent required varies according to the nature of the flour, from 15 c.c. to 40 c.c. per kilo. of flour. No difference in chemical composition can be detected between the bleached and the original flour. The action of the nitrogen peroxide is confined to the yellowish oil of the wheat, but this action is not a destruction of the colour by oxidation. The bleaching action coincides with a decrease in the iodine value of the oil, *e.g.*, iodine values before bleaching of 86·44, 81·70 and 86·10 became respectively, after bleaching, 80·79, 65·20 and 56·70. By combination with the nitrogen peroxide the film of oil covering each granule of starch becomes transparent, and enables the whiteness of the starch to show through. Bleaching by ageing alone, on the other hand, involves an oxidation of the oil and the precipitation of white, fixed, fatty acids. The action of ozone results in an increase in the iodine value, the formation of volatile acids and constancy of the total acidity on keeping. The following test for bleached flours is based on the fixation of the nitrogen peroxide by the oil:—50 grms. of flour are extracted with petroleum spirit, the extract is evaporated at a low temperature, and the oil is redissolved in 3 c.c. of amyl alcohol. The solution is treated in a test-tube with 1 c.c. of alcohol containing 10 grms. of caustic potash per litre. With normal flours the yellow coloration of the liquid does not change, but with bleached flours the colour changes to orange-red, proportional in intensity to the quantity of nitrogen fixed. This test will reveal the presence of 5 per cent. of bleached flour in a sample. The decrease of the iodine value of the oil by bleaching is greater the finer the quality of the flour. With the lower grades the action of the gas tends to be confined to the cellulosic residues and such flours do not lend themselves to the bleaching process. Bleaching has no action on the enzymes of the flour, but the oil shows less tendency to become rancid on keeping in proportion to the quantity of nitrogen peroxide fixed; in this sense the keeping properties of the flour are enhanced by bleaching. —J. F. B.

English Patents.

Pepsin; Manufacture of preparations of —— containing Hydrochloric Acid. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 12,526, June 16, 1905.

See Fr. Pat. 355,560 of 1905; this J., 1905, 1249.—T.F.B.

Coffee Substitute from Grain or Malt; Process of manufacturing a ——. Kathreiner's Malzkaffee Fabr., G.m.b.H., Munich, Germany. Eng. Pat. 17,623, Aug. 31, 1905. Under Int. Conv. Sept. 5, 1904.

The grain or malt is soaked in water or lime-water through which a current of air is blown, and is then placed in a closed vessel containing a solution of "fruit acids" or tannin and subjected to a pressure of about eight atmospheres. The pressure is next reduced to about two atmospheres, and the temperature increased to about 50° C. The mass is then dried at a low temperature under reduced pressure and the treatment repeated until the starch is completely inverted. The product is finally roasted. The solution of "fruit acids" gradually becomes saturated with maltose and may be used for "glazing" the roasted product. The grain may also be treated with chlorine, ozone, or an electric current in the intervals between the above operations, to remove the flavour of the grain oil.—W. P. S.

Carbon Monoxide in the Air; Determination of —— by means of iodic anhydride. A. Levy and A. Pécoul. XXIII., page 201.

ENGLISH PATENT.

Boiler Water; Apparatus for the chemical examination of —— while the boiler is in operation. W. P. Thompson, London. From A. Schmitz, Aachen, Germany. Eng. Pat. 22,021, Nov. 4, 1905.

THE apparatus consists essentially of two glass cylinders secured to a plate. Water from the boiler is allowed to flow into one of the cylinders and there receives the addition of a few drops of indicator solution. The coloured water is then run into the second cylinder and titrated with an acid solution; the quantity of the latter needed is a measure of the amount of sodium hydroxide required to be added to the feed water for softening purposes. The concentration of the sodium salts in the boiler water may be ascertained by allowing the water to flow into a third cylinder provided with a float.—W. P. S.

FRENCH PATENTS.

Water; Process and Apparatus for purifying and sterilising ——. H. Lavollay. Fr. Pat. 358,105, Sept. 28, 1905.

A REGULATED quantity of a solution of a permanganate, preferably calcium permanganate from a reservoir, is allowed to flow into a pipe through which also the water, to be purified, flows *en route* to a mixing vessel provided with baffle-plates, &c. The pressure in the permanganate vessel is slightly in excess of that of the water in the pipe, and the supply of the permanganate is duly regulated by a tap. After leaving the mixing vessel, the water receives the addition of a mixture of ferrous and ferric hydroxides, and is then allowed to settle, being finally filtered if necessary.

Antiseptic Compounds; Making solidified ——. D. Gencse, Assignor to Genese Cereal Manuf. Co., of West Virginia, both of Baltimore, Md. U.S. Pat. 809,795, Jan. 9, 1906.

A SOLIDIFIED antiseptic compound, containing stearoptenes and alcohol, is prepared by heating a mixture of 94 parts of glycerin and 6 parts of sodium stearate to a temperature of about 220° F. for 3—5 hours, then lowering the temperature to about 125° C., and mixing in the volatile ingredients at that temperature.—J. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page* 132.)

ENGLISH PATENTS.

Paper Pulp; Manufacture of —— [for photographic papers]. M. E. le Normant des Varannes and A. R. de Vains, Cebazat, France. Eng. Pat. 505, Jan. 10, 1905.

RAG pulp, after preparation and refining in engines with steel knives, is passed over sand traps to eliminate the heavier particles of metal, and is then formed into half-stuff on a machine. The pressed half-stuff is made up into rolls which are introduced whilst still moist, into closed vessels in which they are subjected to the action of chlorine gas. This gas converts all the metallic particles present in the pulp into soluble chlorides, which are then eliminated by diluting and washing the pulp in a stone engine provided with several washing drums. The washed pulp is then sized and completely refined in a stone refining engine before making into paper.—J. F. B.

Paper; Manufacture of ——. E. F. Morris, Stockport. Eng. Pat. 8325, April 19, 1905.

A COMPOSITION, made up of 2 parts of boiled linseed oil, 0·5 part of Turkey red oil at 50 per cent. strength, 0·5 part of ammonia, sp. gr. 0·880, and 100 parts of water, is added to paper pulp containing 50 parts of dry paper in 4000 parts of water. The paper made from the treated pulp is said to be more resistant in the wet state, and to withstand friction better than ordinary paper.—J. F. B.

Pulp; Process of compacting liquid-borne fibrous ——. J. H. Rivers, St. Louis, U.S.A. Eng. Pat. 16,466, Aug. 14, 1905.

FIBROUS pulp suspended in water is admitted in known quantities into a closed chamber, having a removable false bottom in which a large number of perforated or reticulated moulds are fixed. These moulds are placed as near together as possible, and are all of the same shape in any one plate. A liquid or air pressure is then allowed to act upon the liquid pulp from above, causing the clear water to flow through the perforated moulds and to deposit the suspended material on the walls of the moulds in such a manner that each fibre is compacted against the other fibres under a constant pressure, proportional to the flow of liquid. The mould-plate is then removed and replaced by an empty one.—J. F. B.

Celluloid, Horn, Ebonite or similar substances; Process of producing substitutes for ——. W. H. Story, London. Eng. Pat. 8875, April 27, 1905.

SEE Fr. Pat. 353,995 of 1905; this J., 1905, 1081.—T. F. B.

UNITED STATES PATENTS.

Adhesive [from Waste Sulphite Lyes] and process of making same. F. H. Patch, Richmond, Va. U.S. Pat. 809,739, Jan. 9, 1906.

AN adhesive is prepared from the evaporated liquors resulting from the boiling of wood pulp by the sulphite process. A mixture of oil and rosin is prepared of approximately the same specific gravity as the concentrated sulphite liquor and the mixture is then incorporated with the liquor.—J. F. B.

Cellulose Acetate. A. Eichengrün and T. Becker, Elberfeld, Germany, Assignors to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 809,935, Jan. 16, 1906.

SEE Addition of Jan. 30, 1903, to Fr. Pat. 317,007 of 1901; this J., 1903, 1015.—T. F. B.

FRENCH PATENT.

Cellulose Derivatives and process of making same. G. W. Miles. Fr. Pat. 358,079, Sept. 27, 1905.

ESTERS of cellulose of varying degrees of hydration may be prepared by hydrating to the desired degree the ester of anhydrous cellulose with a monobasic fatty acid, and then precipitating with water; 100 grms. of dry cellulose are allowed to stand for some hours with 400 c.c. of glacial acetic acid and 5 c.c. of sulphuric acid; 280 c.c. of acetic anhydride are then added, and, when the solution has become clear, 40 to 50 c.c. of 10 per cent. sulphuric acid to effect partial hydration of the ester; after standing about 12 hours water is added, and the product is washed. It is soluble in acetone, films being obtained by evaporating the solutions, and becomes plastic on treatment with chloroform. The products obtained by further hydration of the cellulose ester are decreasingly soluble in acetone (see U.S. Pat. 733,729 of 1903; this J., 1903, 961).
—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 134.)

Cocaine Formate. F. Vigier. J. Pharm. Chim., 1906, **23**, 97—98.

Cocaine formate, $C_{17}H_{21}NO_4.CH_2O_2$ is obtained in fine, silky, branching needles, m.pt. 42° C., by saturating cocaine with formic acid. The salt is soluble in water 1 : 42 at 20° C., but is dissociated at 90° C. in aqueous solution, the base separating in oily drops. In 95 per cent. alcohol it dissolves to the extent of 1·3 : 10 at 20° C.; it is sparingly soluble in ether and in chloroform, insoluble in oils. The refractive index of the aqueous solution is 1·334, the specific rotatory power, $[\alpha]_D$ = −56° 40′. —J. O. B

Pinus maritima Mill.; Essential oil from the buds of — —. E. Bellom. Estr. aus Annuario della Soc. Chim. di Milano, 1905, **11**; Chem. Centr., 1906, **1**, 360—361.

By the distillation of buds of *Pinus Maritima Mill.*, collected in the South of France, a bright green oil of fresh aromatic taste, and with the characteristic odour of "pine-needle" oil, was obtained; the yield was 0·681 per cent. from the fresh buds, and 0·517 per cent. from dried buds. The constants of the oil are shown in the following table:—

	Oil from fresh buds.	Oil from dried buds.
Sp. gr. at 15° C.	0·8810	0·8963
$[\alpha]_D^{15°}$	−26·518′	−22·355′
Acid value	0	5·43
Ester value	7·90	8·27
Esters	2·77%	2·92%
Uncombined "alcohol"	—	11·00%
Combined "alcohol"	2·13%	2·28%

The oil is soluble in 10 parts of 90 per cent. alcohol, but is insoluble in 80 per cent. alcohol. It is free from aldehydes, but contains 1·396 per cent. of capryhc acid, which forms the main portion of the free acid present; the esters in the oil are probably those of the lower fatty acids. The chief constituent of the oil is *l*-pinene, and limonene also is probably present. The nature of the alcohol present both in the free and in the combined state was not ascertained. —A. S.

Acetone; Action of — *on Alkali Sulphites.* V. Rothmund. Monatsh Chem., 1905, **26**, 1545—1558.

The author confirms, from the results of physico-chemical experiments, the statements of Lumière and Seyewetz (this J., 1896, 920; 1903, 510, 1014) and Kerp (Arbb. Kaiserl. Gesundh., 1901, **21**, 40) that acetone combines with alkali sulphites in aqueous solution. An interesting fact in connection with this action of acetone is that, with neutral solutions of alkali sulphite, alkalinity is produced, whereas on adding acetone to a solution of free sulphurous acid, an increase of acidity is the result. The explanation of this apparently conflicting behaviour is that acetone-sulphurous acid is practically monobasic, but is an appreciably stronger acid than sulphurous acid. The reaction with alkali sulphites may be expressed by the equation: $(CH_3)_2CO + SO_3 + H_2O = (C_3H_6O)HSO_3 + OH$. —A. S

Camphor; Synthetic — —. U.S. Customs Decision. Chem. and Drug., Feb. 3, 1906.

A decision has been given by the Board of United States General Appraisers sustaining the claim of a firm of importers on the classification of artificial camphor. The importers protested against the assessment of duty by the collector at the rate of six cents per pound on merchandise classified as refined camphor under paragraph 12 of the Tariff Act of 1897. They claimed that the merchandise was crude camphor, and accordingly entitled to free entry under paragraph 515, and the Board upheld the claim, stating that the article in question is not produced from the gum of the camphor-tree, but is the synthetic product, the result of a partially secret process covered by letters patent issued by the United States. The decision says: "The official examiner in the Appraisers' office at the port of New York, experienced in appraising camphor, was unable to say whether the official sample was gum camphor or a synthetic product. We are of the opinion, therefore, that the merchandise before us must be considered to be camphor within the meaning of the term used in the Tariff Act. To hold otherwise would be in effect, in innumerable cases, doubtless an abridgment of the opportunity for carrying out new discoveries in manufacturing processes. The claim of the importers for free entry is therefore sustained." [T.R.]

Rare Earth Metals; Sulphates of the — —. C. Matignon. Comptes rend., 1906, **142**, 276—278.

The author has determined the heats of formation of the sulphates of lanthanum, praseodymium and neodymium and samarium. The following table shows the results, with corresponding figures for other metals for comparison. Q_1, is the molecular heat evolved in the formation of solid sulphate and solid water from solid sulphuric acid and solid oxide, Q_2, that evolved when solid sulphuric anhydride is substituted for solid sulphuric acid.

	Q_1.	Q_2.
	cal	cal
Lanthanum	46·1	65·1
Praseodymium	44·9	60·9
Neodymium	44·7	60·7
Samarium	37·9	56·9
Calcium	63·2	82·2
Barium	83·3	102·3
Lead	42·2	61·1
Silver	36·1	55·1

—J. T. D.

Rare Earths; Contributions to the chemistry of the —, *I.* M. Esposito. Chem. Soc. Proc., 1906, **22**. 20—22.

The methods advocated for the separation of cerium, lanthanum, and "old didymium" have been examined comparatively, with the following results:—

Preparation of the Material.—Rather more than half a kilo. of finely-powdered Swedish cerite was mixed into a paste with water, and 375 grms. of concentrated sulphuric acid were gradually added. Considerable evolution of heat took place and the mass swelled up somewhat. The excess of acid was removed by heat, and the cold white or grey mass was thrown in small portions into five litres of ice-cold water. The silica was removed by filtration and a current of hydrogen sulphide was passed through the solution to precipitate any arsenic, molybdenum, bismuth, copper or lead, which might be present. To the filtrate, oxalic acid was added, which precipitated all the ceria, lanthana, and "didymia" along with lime and traces of the metals of the yttrium group which are present in cerite (Brauner, Chem. Soc. Trans., 1883, **43**, 278). The oxalates were thoroughly washed and dried.

Methods of separation.—For ordinary purposes, the process devised by H. Debray (Compt. rend., 1883, **96**, 928), slightly modified as follows, appears to give rapid and satisfactory results. The dried oxalates were boiled with strong nitric acid until completely decomposed, the solution was evaporated to dryness, the last part of the process being conducted on a sand-bath, and the anhydrous nitrates, mixed with twice their weight of sodium nitrate, were fused in a porcelain dish until no more nitrous fumes were evolved. The cold mass was detached from the dish, coarsely powdered, and digested in warm water acidified with nitric acid. The insoluble, pale yellow ceric oxide was collected and washed with ammonium nitrate solution, as recommended by Schützenberger (Compt. rend., 1895, **120**, 663). If pure water is

used, the finely-divided ceric oxide will pass through the filter. The filtrate was again evaporated to dryness and fused so as to eliminate the remainder of the cerium. The lanthanum and "didymium" were subsequently separated by fractional crystallisation of the oxalates from strong nitric acid solution.

Very pure ceria can be obtained by the following method, depending on the use of chromic acid:—The solution of nitrates is precipitated with caustic soda, and the hydroxides are washed several times by decantation with boiling water. A warm aqueous solution of chromic acid is then added and the whole left for several days. A heavy, yellowish-white precipitate remains, which, on ignition at a gentle heat, yields cerium sesquioxide as an almost white powder without the slightest tinge of red or yellow. When thus obtained, the oxide dissolves readily in boiling hydrochloric acid, and the solution, even when viewed through a considerable thickness, does not show a trace of absorption bands.

UNITED STATES PATENTS.

Dialkylbarbituric Acids; Process of making ——. M. Engelmann, Elberfeld, Germany, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 809,362, Jan. 9, 1906.

SEE Ger. Pat. 162,219 of 1903; this J., 1905, 1189.—T.F.B.

Bismuth Disalicylate and process of making same. B. B. Seifert, Assignor to Chem. Fabr. von Heyden Akt.-Ges., Radebeul, Germany. U.S. Pat. 809,583, Jan. 9, 1906.

SEE Eng. Pat. 19,375 of 1905; this J., 1905, 1323.—T.F.B.

FRENCH PATENTS.

Aldehydes and Ketones; Method of preparing saturated ——. G. Darzens. Fr. Pat. 350,390, Dec. 12, 1904.

UNSATURATED ketones or aldehydes may be converted into the saturated compounds, without reduction of the ketonic or aldehydic group, by catalytic agents, provided these be prepared in such a manner as not to be too energetic in their actions. For example, nickel oxide is mixed with asbestos, and heated to 250°—300° C. in a tube through which a current of hydrogen is passed, until reduction is complete; the temperature is then allowed to fall to 180° or 200° C., and the vapours of the aldehyde or ketone to be hydrogenated are passed over the metal. The temperature at which the metallic oxide is best reduced, and that at which the hydrogenation takes place most effectively are determined in each special case by trial.—T. F. B.

Terpene Alcohols; Process of obtaining ——. A. Haller and C. Martine. Fr. Pat. 350,393, Dec. 12, 1904.

PULEGONE may be reduced by passing it over reduced nickel at about 150° C. (Sabatier and Senderens' method); the product contains no unreduced pulegone, and no pulegol nor menthone; it resembles peppermint oil very closely both in odour and in chemical properties, and appears to consist of a mixture of isomeric menthols. It boils at 107°—110° C. (18 mm.); the fraction boiling at 109°—110° C. at the same pressure, when cooled to 0°C., forms a crystalline mass, from which two crystalline substances were obtained, of m. pts. 43° and 77° C. respectively.—T. F. B.

Dialkylbarbituric Acids; Process of making —— from the products of condensation of Guanylurea, Biuret, Alloxanic Ether, and similar derivatives of Urea and Guanidine, with Dialkylcyanoacetic Esters, Dialkylmalonic Esters, Dialkylmalonyl Halides or Dialkylmalonitriles. E. Merck. Fr. Pat. 357,968, Sept. 6, 1905. Under Int. Conv., Oct. 19, 1904.

COMPOUNDS which are easily converted into urea or guanidine are capable of condensing with dialkylcyanoacetic esters, or with dialkylmalonic esters, halides or nitriles, forming more or less complex imino-compounds, which are easily converted by saponification into the corresponding dialkylbarbituric acids.—T. F. B.

Dialkylmalonic Acid; Process for making Diamides of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 358,085, Sept. 27, 1905.

DIALKYLMALONIC acid diamides are produced by adding the corresponding acid chlorides to about five times their weight of a concentrated aqueous solution of ammonia, the mixture being continuously agitated until the reaction is complete, when the amide is removed by filtration; a further small quantity of the product may be obtained by evaporating the ammoniacal solution, when, moreover, the whole of the ammonia may be recovered.—T. F. B.

Acetylene and Chlorine; Production of compounds of ——. Alby Carbidfabr. Aktieholag. Fr. Pat. 358,146, Sept. 29, 1905. Under Int. Conv., April 28, 1905.

A MIXTURE of chlorine and acetylene gases, diluted with carbon dioxide, is exposed to the action of rays which are capable of inducing reaction, such as radium rays, Röntgen rays, ultra-violet rays and direct sunlight. The presence of the carbon dioxide moderates the violence of the reaction, and the products are ethyl tetrachloride or ethylene dichloride, according to the proportions of the gases in the mixture.—J. F. B.

Oxyhæmoglobin; Preparation of a solution of ——. W. J. J. Hendrikszoon. Fr. Pat. 358,161, Sept. 29, 1905.

FRESH blood is centrifugalised and the serum is decanted off from the clotted globules. The mass of the latter is then mixed with a solution of common salt and again separated by centrifugal action. This operation is preferably repeated three times, in order to remove the whole of the serum. The clotted blood is then treated in an agitating machine with finely chopped asbestos and water. The globules are thus broken up and the oxyhæmoglobin enters into solution. The liquid is filtered, the residues of tissue being retained on the filter by the asbestos, and a clear solution of oxyhæmoglobin is obtained.—J. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 135.)

Pyridine as a ripening agent for Silver Bromide emulsions. Lüppo-Cramer. Phot Korr., 1905, **42**, 538. Chem.-Zeit., 1906, **30**, Rep., 32.

THE method of preparing silver bromide emulsions described by Witt (Ger. Pat. 151,752; this J., 1904, 836) has been examined by the author, who finds that pyridine offers no advantages over ammonia as a "ripening" agent. The solvent action of pyridine upon silver bromide is so little more than that of ammonia solution, that even after several hours "ripening" the development of the "grain" is hardly more than when pyridine is not present. On the other hand, the degree of sensitiveness is not increased, and can be attained just as readily and certainly by the methods hitherto employed.—C. A. M.

Colour Photography; "Bleaching-out" process of ——. Kümmel. Phot. Runds., 1905, **19**, 328. Chem.-Zeit., 1906, **30**, Rep., 32.

The author having found that a red "fog" invariably occurs with the mixture of dyestuffs used by Neuhauss, has examined the different Erythrosins: tetrachlortetrabromofluorescein, tetraiodofluorescein, and diiodofluorescein, and has found that the first is but little sensitive, whilst the last is extraordinarily sensitive, much more so than the tetraiodofluorescein. The sensitiveness of the red dyestuffs can be increased by the use of the ammonium salts instead of the sodium salts. Very pure dyestuffs are less sensitive than those containing traces of impurities, notably iodine. The red "fog" can be prevented by replacing a fourth part of the tetraiodofluorescein by diiodofluorescein. Iodine appears to have a catalytic action in increasing the sensitiveness of the Erythrosins. In many cases the sensitiveness to light can be considerably increased by the addition of colloidal gold solution. The coloured gelatin can be easily transferred to paper as follows:—It is poured on to a piece of plate glass which has previously been cleaned and polished with a solution of wax and colophony in benzol. When dry, the gelatin is moistened on the surface with a brush, and a piece of paper similarly moistened laid upon it, pressed down, and left to dry. The coloured gelatin film adheres to the paper, and can be removed with it from the plate.

—C. A. M.

Coloured Photographs by Wood's method. R. Neuhauss. Phot. Runds., 1905, **19**, 332. Chem.-Zeit., 1906, **30**, Rep., 32.

In Wood's method three negatives are taken through a red, green and blue light filter respectively, and diapositives made from them and used for making copies on chrome gelatin plates, a diffraction grating being placed between the diapositive and the plate. For the diapositive taken through the red colour filter a screen ruled with about 1000 lines to the square centimetre, is used; for the green diapositive one with 1250 lines; and for the blue diapositive, one with 1500 lines. In the case of the red diapositive, for instance, only those parts which were red in the original are copied, since only those parts are transparent. The colours only appear when viewed through an apparatus specially constructed for the purpose. The ruled screen used for the red copy breaks up the white light into green colours and projects a spectrum at the point where the eye of the observer is applied. It was noticed that, in certain photographs taken by Joly's method, the lines of the ruled screen cut the lines of the Joly ruled plates at right angles, and excellent colour effects were produced.—C. A. M.

Cyanine Dyestuffs; Constitution of ——. W. König. IV. page 173.

Acetone; Action of —— on alkali sulphites. V. Rothmund. XX., page 196.

Paper Pulp; Manufacture of —— [*for photographic papers*]. M. E. le Normant des Varannes and A. R. de Vains. Eng. Pat. 505, Jan. 10, 1905. XIX., page 195

Photographic Paper; Self-toning ——. C. S. Poulsen, Valby, Denmark. Eng. Pat. 19,850, Oct. 2, 1905

A durable self-toning photographic paper is produced by adding a dyestuff such as Fuchsin or Methyl Violet to an emulsion in which part of the silver is present as cyanide or thiocyanate. The dyestuff is said to prevent the reaction between the silver and gold salts previous to toning. For instance, for every kilo. of emulsion may be added 5—15 mgrms. of the dyestuff, 3—6 grms. of an alkali cyanide or thiocyanate, and 2—3 grms. of gold chloride. The tones produced are stated to depend only on the concentration of the salt solution subsequently used, not on duration of immersion; tones from red-brown to blue-black are said to be obtainable on such paper.—T. F. B.

Photographic Images; Manufacture of coloured ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst a/Main, Germany. Eng. Pat. 7557, April 10, 1905.

The specification of Fr. Pat. 337,054 of 1903 (this J., 1904, 455) described the production of coloured images by dyeing a bichromated gelatin "image," and transferring the dyestuff to paper coated with gelatin ("pinatype" process). It is found that many dyestuffs do not give good results by this method, the gelatin paper being uniformly coloured (*e.g.*, with a Safranine or with Tartrazine), or a reversed image may be produced. The present patent claims the employment of the following dyestuffs for this process, all of which are stated to give excellent results:—The "Mikado dyestuffs" from *p*-nitrotoluenesulphonic acid; the soluble azo dyestuffs derived from dehydrothiotoluidine, Primuline, or their substitution products; natural Carmine; the sulphonic acids of Induline and Nigrosine; Naphthazine Blue; certain of the diamine dyestuffs (*e.g.*, Diamine Pure Blue, Dianil Blue, Dianil Yellow, Dianil Garnet); and "arylido-anthraquinonesulphonic acids" or their derivatives.—T. F. B.

United States Patent.

Photographic Prints; Process for producing multi-coloured ——. S. Vathis, Paris. U.S. Pat. 809,651, Jan. 9, 1906.

See Eng. Pat 579 of 1902; this J., 1902, 723.—T.F.B.

French Patent.

Photographic Paper; Self-toning ——. C. S. Poulsen. Fr. Pat. 358,203, Oct. 2, 1905.

See Eng. Pat. 19,850 of 1905; preceding these.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page* 135.)

Nitrocellulose; Decomposition of —— at temperatures below its ignition point. A. Saposchnikow and W. Jagellowitsch. J. russ. phys.-chem. Ges., 1905, **37**, 822—828. Chem. Centr., 1906, **1**, 339.

The authors examined the rate of decomposition of a specimen of ordinary pyroxylin of the approximate composition, $C_{24}H_{29}(NO_2)_{11}O_9$, at seven different temperatures between 120° and 150° C. The method adopted, consisted in measuring the volume of gas evolved from a weighed quantity of the pyroxylin in a definite interval of time at a given temperature (compare Mittasch, this J., 1903, 1208). Curves constructed by using the volume of gas (v) and the time (t) as ordinates had distinct bends, indicating the autocatalytic character of the reactions. The relation between the temperature and the maximum reaction-velocities $\left(\frac{dv}{dt}\right)$ corresponding to the bends in the curves, may be represented by two lines, corresponding to the equations:

Between 120° and 130° C., $\left(\frac{dv}{dt}\right)$ max. $= -2{\cdot}22 + 0{\cdot}192t$,

Between 135° and 150° C., $\left(\frac{dv}{dt}\right)$ max. $= -64{\cdot}22 + 0{\cdot}48t$;

these lines intersect at the point corresponding to 135° C. The gaseous decomposition products consisted of carbon dioxide, carbon monoxide, nitric oxide and nitrogen; the relative proportions of the different gases were not affected to any considerable extent by the temperature. At temperatures below 135° C., the solid residue contained no hydrogen, whilst at temperatures above 135° C. it contained hardly any nitrogen (see also this J., 1904, 1112).—A. S.

English Patents.

Explosion or Percussion Caps; Process for the manufacture of safety ——. F. Gehre, Munchen, Germany. Eng. Pat. 19,402, Sept. 26, 1905.

Copper caps are used, filled with solid di- or trinitromesitylene, di- or trinitropseudocumene, or di- or trini-

troxylene, the whole covered with a thin coating, amounting to about 0·3 grm., of mercury fulminate. By this means it is claimed that a quicker and more violent explosion is ensured.—B. J. S.

Explosives; Impts. in ——. G. Roschke, Hamburg, Germany. Eng. Pat. 25,780, Dec. 11, 1905.

The invention comprises the use of copper oxalate as a cooling agent in fire-damp explosives not only with dinitrobenzene and turmeric (as in Eng. Pat. 21,189 of 1902; this J., 1902, 1471), but also with such carbon-containing substances as woodmeal or dust, naphthalene, or colophony, with or without the addition of a nitro-compound. —B. J. S.

UNITED STATES PATENTS.

Nitroglycerin; Process of making ——. C. L. Reese, Assignor to the Eastern Dynamite Co., Wilmington, Dela. U.S. Pat. 804,817, Nov. 14, 1905.

The object of the invention is to accelerate the separation of nitroglycerin from the emulsion formed on nitration of glycerin. The author has discovered that the emulsifying effect is caused by the presence of small quantities of colloidal silica. It is therefore proposed to add a small percentage (0·001 per cent.) of sodium fluoride (or other compound of fluorine) to the glycerin before nitration. The silicon is thereby converted into silicon tetrafluoride, and the separation of the nitroglycerin is effected more readily.—B. J. S.

Match. A. Swoboda, Vienna, Assignor to W. Bokmayer, Modling, Austria. U.S. Pat. 810,363, Jan. 16, 1906.

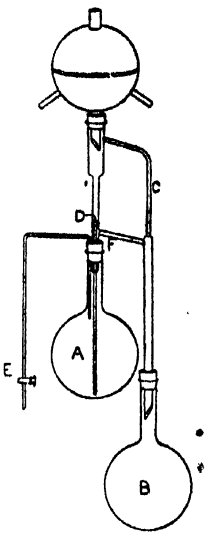
See Fr. Pat. 355,846 of 1905; this J., 1905, 1256.—T.F.B.

FRENCH PATENT.

Explosives; Impts. in ——. C. Girard. Fr. Pat. 350,371, Dec. 5, 1904.

Claim is made for explosives composed of nitrates fused together, either alone or mixed with other explosive or combustible substances. For example, a mixture prepared by fusing together 80 parts of ammonium nitrate and 88 parts of guanidine nitrate is stated to form a powerful explosive.—A. S.

XXIII.—ANALYTICAL CHEMISTRY.



(*Continued from page* 140.)

APPARATUS, ETC.

Extraction of Liquids with ether; Improved apparatus for the continuous ——. R. S. Bowman. Chem. Soc. Proc., 1906, **22**, 24—26.

The apparatus comprises a simple system of tubes, a condenser, and two ordinary flasks, preferably round bottomed. The liquid to be extracted is placed in the flask, A, in sufficient quantity to very nearly fill the flask to the bottom of the neck. This flask may frequently be replaced with advantage by a wide test-tube. From one-eighth to one-fifth of this volume of ether, with which the substance is to be extracted, is placed in the flask B, which is heated on a water-bath or electric heater. The ether passing as vapour up tube, C, is condensed in the condenser and falls back and collects in the inner tube, D. A column presently accumulates in D, long enough to force its way through the liquid in A, and there is then a constant succession of small drops of ether ascending in A, collecting on the surface of the liquid, and finally overflowing at F, and returning to the flask, B.

On completion of the process of extraction, the neck of the flask will be filled with ether. There will also be a column of ether in tube D, reaching a few centimetres above tube F, and hence the neck of the flask may be emptied by opening the stopcock, E, and allowing the ether to run off into some vessel. If necessary, the flask

may now be replaced by a similar one containing a fresh portion of the liquid to be extracted and the process resumed.

ENGLISH PATENT.

Gas; Burner for testing ——. C. C. Carpenter, London. Eng. Pat. 24,828, Nov. 30, 1905 (see this J., 1905, 1085).

For the purpose of testing photometrically coal gas of different composition or quality, a "tri-current" argand burner is so constructed as to allow a simultaneous adjustment of the three currents of air supplied to the burner. The gas is supplied from the socket by means of three narrow tubes to an annular chamber from which it issues through a ring of holes so as to form a hollow flame. The air admitted to the inner and outer surfaces of the flame enters through passages in an adjustable disc, provided with a threaded socket, so that the disc can be raised and lowered, thus diminishing or increasing the air supply as required. The additional supply of air to the chimney, necessary for "tri-current" burners, is admitted partly through a small side channel permanently open, and partly through a vertical ring of ports, or orifices, which may be covered by a flange attached to the adjustable disc. In the case of poor gases, the small channel admits sufficient air, whilst more air is admitted for rich gases by lowering the disc, thus uncovering these ports and simultaneously increasing the two other air supplies.—R. L.

INORGANIC—QUANTITATIVE.

Halogens; Use of hydrogen peroxide for the quantitative separation of the ——. J. Jannasch and F. Zimmermann. Ber., 1906, **39**, 196—197.

The authors find that iodine can be separated quantitatively from bromine and chlorine by means of hydrogen peroxide in acetic acid solution. The mixture containing the three halogens is dissolved in 120—150 c.c. of water, 15 c.c. of pure glacial acetic acid and 3 c.c. of 30 per cent. hydrogen peroxide are added, and the liberated iodine is distilled over in a current of steam. The iodine is collected in three connected receivers of which the first contains 80—100 c.c. of water, 10 grms. of hydrazine sulphate, and 10 c.c. of strong ammonia, whilst the other two each contain 25 c.c. of water, 2 c.c. of ammonia, and 0·5 grm. of hydrazine sulphate. When the distillation is complete, the contents of the receivers are mixed, acidified cold with 30—40 c.c. of concentrated sulphuric acid, and the iodine precipitated as silver iodide.—A. S.

Silver; Determination of —— in large quantities of silver coins. C. Hoitsema. Z. anal. Chem., 1906, **45**, 1—14.

The coins to be assayed, are sampled down to 1000, from each of which, cylinders or sectors are stamped in a way which varies somewhat for each (Dutch) coin. If necessary, the "pitons" so obtained are further sampled down by allowing them to drop through a funnel having a narrow opening, a part only of the heap formed, being taken. The actual determination of the silver is made by Stas's modification of the Gay-Lussac method, except that 20 grms. of the sample are used instead of 1 grm. as heretofore. For the control test on pure silver, 5 grms. of silver are taken. Pipettes holding 2000 c.c. and 500 c.c. are used instead of the usual 100 c.c. Stas pipette. The silver is weighed out to 0·02 mgrm., and by using special precautions as to the cleaning and emptying of the pipettes, keeping the temperature of the solutions constant, &c., the silver value is obtained with an error of only 0·00001 of the total.—A. G. L.

ORGANIC—QUALITATIVE.

Coniine, Nicotine, and Sparteïne; Differentiation of ——. C. Reichard. Pharm. Centralh., 1905, **46**, 309—313; 385—388.

With copper oxychloride.—A small quantity of the oxychloride, reduced to powder, is moistened with a drop of the alkaloid, then with hydrochloric acid. Nicotine gives a persistent violet-blue reaction; coniine a bright green which becomes paler; sparteïne gives no reaction.

With α-nitroso-β-naphthol.—A few drops of a solution of the reagent are evaporated in a small porcelain capsule. A trace of the bases is added to the residue; coniine gives a deep green colour, nicotine a yellowish-brown tint.

With ammonium sulphomolybdate.—Nicotine gives a greenish-yellow colour when spotted out with the reagent; coniine and sparteïne give no reaction. If ammonium persulphate be added to the mixture, nicotine develops a violet-purple colour, coniine and sparteïne a yellow tint.

With potassium sulphovinate and sulphuric acid.—Nicotine gives first a yellow, then a red colour; sparteïne, and coniine, no reacion.

With sodium picrate.—Nicotine gives a reddish-yellow colour, sparteïne and coniine no change. On adding ammonium persulphate and potassium thiocyanate to the mixture, sparteïne gives an orange-red tint; nicotine, no reaction; coniine, a very feeble orange shade.

With ferric chloride and potassium thiocyanate, spotted out on porcelain and dried, sparteïne gives a blue-violet or violet-red shade; nicotine and coniine give a green colour.

With ferric chloride and potassium ferrocyanide, mixed in solution, and the blue liquid spotted out and dried, coniine gives a green-brown reaction; nicotine does not affect the original blue tint for some time, then changes it to green; sparteïne gives a violet colour. On adding potassium thiocyanate to the mixture, the colour changes to pale blue with sparteïne, but no change occurs with nicotine or with coniine.—J. O. B.

Sugars; Colour reactions of the principal ——. N. Schoorl and C. J. van Kalmthout. Ber., 1906, **39**, 280—285.

The authors have subjected the colour reactions prescribed by Pinoff (this J., 1905, 1192), for the detection of the various sugars in mixtures, to a critical examination. They conclude that none of these reactions are capable of distinguishing between levulose and cane sugar, owing to the extreme ease with which the latter is inverted. Neither can levulose be detected in presence of dextrose unless it be present in considerable quantities, *e.g.*, more than 10 per cent. The resorcinol test (reaction 3, *loc. cit.*) is a modification of Seliwanoff's test, which is by no means an improvement. The best modification of this test for the detection of levulose or cane sugar in presence of dextrose and other aldose sugars consists in reducing the concentration of the acid to N/1 and working in aqueous media, dextrose will then show only a slight yellow coloration after heating for 15 minutes. The bichromate test (reaction 4) shows both levulose and cane sugar, and is only available when the proportions of these sugars a above 10 per cent. The molybdate test (reaction 5) is modification of Cotton's test for the presence of cane sug in milk. The modification is no improvement, since onl milk sugar fails to develop the blue coloration under th conditions specified. The only way to detect levulose is t concentrate it in the mixture by extraction with alcoh and ether, or, by precipitation as calcium levulosate. Th authors speak highly of Berg's test (this J., 1904, 1240 as a means for identifying a pure sugar as an aldose or ketose, but it cannot be used, as claimed, for testing the freedom of aldose sugars from ketoses.—J. F. B.

ORGANIC—QUANTITATIVE.

Caoutchouc; Torrey's method of determining pure ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 418.

The author has examined Torrey's method of estimating rubber (this J., 1905, 1193). He finds that the method is quite useless practically, since in attempting to match the alkaline solution of the nitrated product with that of the standard solution, the colour is not perceptibly altered by addition of quantities of water ranging, with different specimens of rubber, from 50 to 100 c.c.—E. W. L.

Sugar; Influence of the lead precipitate on the polarisation of ——. W. D. Horne. Bull. Assoc. Chim. Sucr. Dist., 1905, **23**, 635—637.

In reply to the criticisms of H. and L. Pellet on the author's method of defecating raw sugars with dry basic lead acetate (this J., 1904, 340), it is pointed out that the quantity of sugar retained by the precipitate after separation of the portion freely soluble in cold water, is less than the errors of observation in the polariscope, and one-tenth only of the augmentation due to the volume of the precipitate. The increase observed in the specific gravity of the lead precipitate after removing the lead with sulphuretted hydrogen, concentrating on the water-bath and re-precipitating, is to be attributed to a considerable modification of the organic matter of the original precipitate by the treatment with hydrogen sulphide, and by evaporating at the high temperature for the sake of concentration. Whether the process is novel or not, it is only since the production, within the last two years, of a dry basic lead acetate of fixed composition that the method became practicable. The amount of moisture in samples examined, varied from 0·14 to 2 per cent., and where only 0·35 grm. of the lead salt is used can have no appreciable effect on the polarisation. Excess is easily avoided, since each particle of the powder added, produces a precipitation, and no more is added as soon as the lead salt begins to give only a slight precipitate. There is no salt left in solution as the filtrate is free from lead.—L. J. de W.

Sugar; Influence of the lead precipitate on the precipitation of ——. H. and L. Pellet. Bull. Assoc. Chim. Sucr. Dist., 1905, **23**, 638—639. (See preceding abstract.)

The quantity of sugar retained by a lead precipitate in a sugar solution varies with the quantity of the precipitate, and the concentration of the sugar solution. This quantity does not correspond to that which may be determined in the washed precipitate, since on washing, the precipitate gives up a certain quantity of sugar, as has been observed in the case of animal charcoal. It does not appear evident why a precipitate decomposed by sulphuretted hydrogen should yield a very different substance from that which was precipitated, for this is the general method of separating many substances without alteration. In the first precipitation, however, taking place in a solution rich in sugar, more sugar is retained than in the second case, when the solution is poor in sugar. This is the method adopted of freeing a precipitate from impurities carried down with it. It is not astonishing, therefore, that a different specific gravity was found in the two precipitates.—L. J. de W.

Sugars [Cupric-Reducing]; Determination of —— by means of Zeiss' Immersion Refractometer. B. Wagner and A. Rinck. Chem.-Zeit. 1906, **30**, 38-39.

The authors propose to determine the quantity of cuprous oxide, precipitated from Fehling's solution by reducing

sugars, by means of the refractometer instead of by weighing or titration; 30 c.c. of alkaline tartrate solution, containing 346 grms. of Rochelle salt and 250 grms. of caustic potash per litre, 30 c.c. of Fehling's copper sulphate solution, and 60 c.c. of water, are boiled in a beaker, and 25 c.c. of the sugar solution, of a concentration not exceeding 1·04 per cent., are added. The mixture is boiled; the precipitate is collected in a filter-tube containing asbestos, and is dissolved after washing, in not more than 5 c.c. of 25—30 per cent. nitric acid. The filter is washed three or four times and the solution is evaporated to dryness on the water-bath. It is important to remove the product from the water-bath as soon as the crystalline cupric nitrate is formed, otherwise some basic salt may be produced. The cupric nitrate is dissolved in exactly 5 c.c. of nitric acid, the refractometer value of which is known, the solution is diluted to 10 c.c. at 17·5° C. with water, and is examined in the refractometer. The results are not exactly proportional to the values of the readings, which are converted into terms of dextrose by the following table:—

Dextrose.	Scale divisions	Difference for 0·04 per cent. dextrose.
Per cent.		
0·04	20·8	
		2·4
0·08	23·2	
		2·2
0·25	32·9	
		2·2
0·29	35·1	
		2·0
0·80	62·4	
		2·0
0·84	64·4	
		1·9
0·96	70·4	
		1·9
1·00	72·3	

The method is claimed as more accurate, more rapid, and more economical than the usual methods.—J. F. B.

Pentoses; Volumetric method for determining ——. A. Jolles. Ber., 1905, **39**, 96—97.

0·2—1·0 grm. of a pentose or pentose-yielding material is mixed with 200 c.c. of hydrochloric acid of sp. gr. 1·06, and steam is passed into the mixture until the formation of furfural is shown by Bial's reagent, to be complete, 100 c.c. of hydrochloric acid being added during the distillation. An aliquot portion of the distillate is neutralised and mixed with a known volume, in excess, of standard potassium bisulphite solution, which reacts with the furfural according to the equation:—

$$C_4H_3O.CHO + KHSO_3 = C_4H_3O.CH(OH).SO_3K.$$

After about two hours' standing, the excess of bisulphite is measured by titration with iodine solution; 1 c.c. of N/1 bisulphite solution corresponds to 0·07505 grm. of pentose.—T. H. P.

Barley; Determination of extract of ——. G. Graf. Z. ges. Brauw., 1906, **29**, 25—26.

The author has devised the following modification of the method for determining extracts of barleys in use in the "Wissenschaftliche Station für Brauerei in Munich." The barley is ground so as to give, when tested by Vogel's grading sieve, 86·2 per cent. of fine, and 13·8 per cent. of coarse grist, together with 0·2 per cent. of husks. 25 grms. of this grist are soaked for 15 hours with 25 c.c. of malt-extract, and 50 c.c. of water. The mash is then slowly heated, with stirring and replacement of the evaporated water, to boiling on a sand-bath and the boiling maintained for 5—10 minutes; after gelatinisation occurs, it is advisable to add a few c.c. of hot water. After cooling to 50° C., 75 c.c. of malt extract are added and the whole heated in 25 minutes, to 75° C., at which temperature it is kept until saccharification is complete. When cold, the mash is made up to a weight of 225 grms., the remaining procedure being as in the determination of the extract of malt as described below. The malt-extract is best prepared by mixing coarsely ground pale malt with water in the ratio of 1 : 5 and allowing to stand for two hours, with occasional stirring. To determine the extract contained in the malt extract employed, about 80 grms. of the latter are boiled and then made up to the original weight by the addition of water. The specific gravity of the filtered liquid is then measured and the corresponding extract-content read off from Balling's tables. The author's method gives results in good agreement with those obtained by Reichard and Purucker's method (Z. ges. Brauw., 1904, **27**, 345 and 366; 1905, **28**, 37; this J., 1905, 1120). —T. H. P.

Carbon Monoxide in the air; Determination of —— by means of iodic anhydride. A. Levy and A. Pécoul. Comptes rend., 1906, **142**, 162.

Gautier has shown that carbon monoxide when mixed with air, reduces iodic anhydride, and that the reaction is perfectly quantitative even when the carbon monoxide is extremely dilute. Acetylene also reduces the anhydride but the reaction is not complete, and is only slight when the acetylene is highly diluted. The authors have designed a method for the detection and determination of carbon monoxide in air, based on this reaction, the iodine liberated being absorbed in chloroform and determined colorimetrically. In studying the possible error due to the presence of acetylene, they have found that 4 parts of acetylene per 10,000 produce only the very faintest tint, and 1 part per 10,000 produces none at all, whereas the presence of 1 part of carbon monoxide per 10,000 produces an intense coloration. It is concluded, therefore, that in testing normal air the possible presence of acetylene may be neglected, but that in testing industrial gases arrangements must be made for the previous absorption of the acetylene, as well as of sulphuretted hydrogen, nitrous fumes and other disturbing gases. When extreme accuracy is required, the iodine liberated is to be absorbed in a solution of potash.—J. F. B.

Acetylene; Combustion of —— by oxygen. P. M. Beaupré. II., page 168.

Chloroform in air, blood and aqueous liquids; Determination of small quantities of ——. M. Nicloux. Comptes rend., 1906, **142**, 163—165.

Small quantities of chloroform, not exceeding 0·1 grm., in alcoholic solutions, are determined by making up the volume of the solution to 60 c.c. with alcohol, and boiling the liquid under a reflux condenser with 10 c.c. of 10 per cent. pure alcoholic potash for about 1 hour. The flask is cooled, 15 c.c. of water are added, and the liquid is made exactly neutral to phenolphthalein. Potassium chromate is added and the chlorine is titrated with a solution of silver nitrate containing 8·535 grms. of the salt per litre, 1 c.c. of which corresponds to 2 mgrms. of chloroform.

For the determination of chloroform in air, the air is passed at the rate of 1 litre in 30 minutes through two absorption tubes containing 95 per cent. alcohol, which absorbs the chloroform. For the determination of chloroform in blood or other aqueous liquids, the liquid is diluted with five times its volume of 80—95 per cent. alcohol, acidified with 0·25 grm. of tartaric acid. The mixture is distilled in a Schloesing's fractionating flask and the distillate is collected in 10 c.c. of 95 per cent. alcohol, until one-third of the total liquid has been distilled. The determination of the chloroform in the alcoholic solution is then conducted as above. There appears to be a systematic error inherent in the method whereby the results come out 1·5—2 per cent. too low.—J. F. B.

Strophanthin, Determination of —— in strophanthus seeds and in strophanthus tincture. Caesar and Loretz' Report, September, 1905; Pharm. Centralh., 1905, **46**, 859.

Seven grms. of moderately finely crushed strophanthus seeds are introduced into a flask with 70 grms. of absolute alcohol, and the gross weight is noted. The mixture is then digested on the water-bath, under a reflux condenser for one hour. After cooling, the original weight is made up by the addition of absolute alcohol and the liquid is filtered; 50·5 grms of the filtrate, equivalent to 5 grms. of the seeds, are then evaporated in a porcelain capsule on the water-bath. When the alcohol has been driven

off, the residue is treated with light petroleum spirit, and the solution of fat thus obtained, is filtered through a small plain filter. After washing with more light petroleum spirit, the insoluble residue on the filter is washed back into the capsule with 5 to 8 grms. of boiling water. The whole is then heated to boiling and treated with 5 drops of basic lead acetate solution. The lead precipitate is collected on a filter, and washed with boiling water until the filtrate is free from bitter taste. The filtrate containing the glucoside is then heated to boiling, and freed from lead by means of hydrogen sulphide. After heating to expel the gas, the lead sulphide is filtered off, and washed until free from bitterness. If only the crude strophanthin is to be determined, an aliquot part of this filtrate may be evaporated to dryness in a tared capsule and weighed. If the amount of pure strophanthin be required, the glucoside in the above filtrate is hydrolysed into strophanthidin, by boiling gently for two hours with 5 drops of hydrochloric acid. When the volume of the liquid is reduced to 10 c.c., it is made up to about 20 c.c. by the addition of distilled water. The cold solution is then twice shaken out with two successive washings, each of 10 c.c. of chloroform, and the chloroform extracts collected in a small tared flask. The aqueous portion is again boiled for half an hour, then again shaken out thrice with 10 c.c. of chloroform, these chloroform extracts being added to those previously obtained. The aqueous solution is again boiled, and if any bitter taste is evident, again shaken out with chloroform, the process being repeated until no more bitterness is evident. The bulked chloroform extracts are then distilled to dryness, the residue dried till of constant weight, and weighed as strophanthidin, 1 part of which = 2·182 parts of strophanthin.

In the case of strophanthus tincture, 51 grms. are evaporated to drive off the alcohol, the residue treated with 15 drops of basic lead acetate and the process continued as above.—J. O. B.

Aconite Root; Alkaloidal valuation of ——. Cæsar and Loretz' Report, September, 1905; Pharm. Centralh., 1905, **46**, 860.

Seven grms. of moderately finely powdered aconite root are macerated for half an hour in a closed flask with 70 grms. of ether and 5 grms. of 15 per cent. caustic soda solution, with frequent agitation. The ethereal layer is then run through a pad of absorbent cotton wool, and set aside until clear. Fifty grms., or an aliquot part of the clear ether extract, 10 grms. of which = 1 grm. of root, are then weighed off, and shaken out with 15, 10, and 10 c.c. in succession, of a 1 per cent. solution of hydrochloric acid. The acid extract is filtered into a separator, rendered alkaline with ammonia, and shaken out with 15, 10 and 10 c.c. of chloroform. The chloroform extracts are filtered into a small tared flask, the solvent is distilled off, and the residue moistened twice with 5 c.c. of ether, each lot of ether being driven off separately, and then dried to constant weight in the exsiccator. To determine the amount of alkaloid in this residue volumetrically, it is dissolved in a few c.c. of absolute alcohol, treated with 20 c.c. of water and a few drops of hæmatoxylin indicator, then titrated with N/10 hydrochloric acid, each c.c. of which is equivalent to 0·0645 grm. of aconitine.—J. O. B.

Iodothymol ["*Aristol*"]*; Determination of iodine in* ——. H. Cormimbœuf. Ann. Chim. anal. appl., 1905, **10**, 453—454.

Half a grm. of the iodothymol is intimately mixed with 3 grms. of pure anhydrous sodium carbonate, and the mixture is fused in a small crucible until all the organic matter has been burnt off. The cooled residue is then dissolved in warm water, the solution filtered, and treated with half its volume of solution of ammonia. The iodine is then precipitated in the usual manner with silver nitrate, and weighed as silver iodide. The amount of chloride present as impurity is found by acidifying the filtrate from the silver iodide precipitate with nitric acid, when silver chloride is precipitated, which is collected and weighed.—J. O. B.

Acetaldehyde; Determination of ——. Seyewetz and Bardin. Bull. Soc. Chim., 1905, 1000—1002.

The aldehyde solution is diluted so that it contains not more than approximately 7 to 8 per cent. Ten c.c. of this solution are added to 40 c.c. of 10 per cent. solution of anhydrous sodium sulphite, containing one or two drops of phenolphthalein indicator. In order to avoid loss, the solutions and mixture should be kept at 4° to 5° C. The solution is then titrated in the usual manner with N/1 sulphuric acid. The amount of aldehyde present is deduced from the quantity of acid used, according to the equation

$$2Na_2SO_3 + 2CH_3CHO + H_2SO_4 = (SO_3HNa,CH_3CHO)_2 + Na_2SO_4.$$

The presence of paraldehyde and acetal is without influence on the reaction; if acetic acid be present it must be determined separately.—J. O. B.

Formaldehyde; Determination of —— in Formaldehyde Pastilles (*Trioxymethylene*). E. Rüst. Z. angew. Chem. 1906, **19**, 138—139.

The author has modified the hydrogen peroxide method in such a way as to permit of operating on a large amount of substance, and of using normal acid and alkali with phenolphthaleïn as an indicator. A funnel is placed in the mouth of a 250 c.c. conical flask, and 1·9—2·0 grms. of the powdered substance weighed into it from a tube. The substance is washed down into the flask by about 70 c.c. of N/1 sodium hydroxide solution delivered from a burette, and dissolved. Then 9—10 grms of neutral 30 per cent. hydrogen peroxide are added, at first in small portions and cautiously, so as to avoid heating and frothing, then more rapidly. After two hours the contents of the flask are heated cautiously to boiling, and boiled to destroy the excess of peroxide. The funnel is now rinsed into the flask, a drop or two of phenolphthaleïn added, the liquid titrated with N/1 acid to very slight excess, and taken back with the N/1 sodium hydroxide. Any original acidity or alkalinity in the substance must be tested for, and if found, titrated and allowed for.—J. T. D.

French Patent.

Musts, Wines, and other Acid Liquids; Process for determining the total acidity of ——. P. P. A. Andrieu. Fr. Pat. 357,957, July 29, 1905.

The apparatus consists of an ordinary gas-burette fitted on a wooden stand and connected with a reservoir of water. A side tube at the top is connected with a gas evolution flask. Into this flask, 20 c.c. of a solution containing 5 grms. of sulphuric acid per litre are introduced, and 4 c.c. of a saturated solution of sodium bicarbonate are placed in a small tube which is supported in the flask. The apparatus having been connected up, the gas is evolved and the level of the water in the burette is read off. The reading so obtained is adjusted on a calibrated slide rule opposite the figure 5 on the fixed sulphuric acid scale of the rule. The operation is then repeated with the liquid under examination, and the new volume of gas evolved, corresponds on the slide rule with the acidity of the liquid in grms. of sulphuric acid per litre.—J. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 140.)

Gold; Double Acetates of ——. *Crystallised barium auryl hydroxide.* F. Weigand. Z. angew. Chem., 1906, **19**, 139—140.

If the compounds of alkaline earth and gold oxide formed by precipitating auric chloride with baryta-water (strontia, lime, magnesia, lead or zinc hydroxide) be heated, while still moist, with acetic acid, crystallisable salts are formed, shown by analysis to be $M(C_2H_3O_2)_2.2Au(C_2H_3O_2)_3$. They are very stable in the dry state, but their aqueous solutions slowly decompose.

From the filtrate, after precipitating auric chloride with baryta-water, small yellow-green crystals slowly separate, which have the composition $BaO_2(AuO)_2.5H_2O$. —J. T. D.

Titanium Tetrachloride and Stannic Chloride; Preparation of ——. Ber., 1905, **39**, 249—250.

TITANIUM dioxide is heated in a tube of hard glass, and chloroform vapour is passed over it. The reaction, $TiO_2 + 2CHCl_3 = TiCl_4 + 2CO + 2HCl$ occurs, and the tetrachloride is condensed in a cooled receiver. By-reactions occur, a colourless gas decomposed by water with formation of titanium dioxide, and which is, therefore, probably titanium hydride, being formed, besides carbonyl chloride and carbon dioxide. If the reaction be carried on at a high temperature, white needles condense in the receiver, which have the characters of hexachlorobenzene. Stannic oxide behaves similarly, but silica is unaffected.—J. T. D.

Amines; Action of Oxygen on aliphatic —— in presence of Copper. W. Traube and Schönewald. Ber., 1906, **39**, 178—184.

SCHÖNBEIN (Ber. Akad. Wissensch., Berlin, 1856, 580) and Tuttle (Annalen, **51**, 283) showed that by the action of oxygen on ammonia solution in presence of metallic copper, part of the ammonia is oxidised to nitrous acid. The authors have examined the action of oxygen on ethylamine and methylamine in presence of copper. They find that the metal is oxidised, but no nitrous acid is produced; the amine is oxidised to the corresponding aldehyde (formaldehyde from methylamine, and acetaldehyde from ethylamine) and ammonia is split off. With glycocoll, ammonia and glyoxalic acid are formed, but in this case nitrous acid is also produced.—A. S.

Glucosides and Albuminoids; Alterations of the Refractive Indices of the — — under the action of Enzymes, Acids, and Bacteria. F. Obermeyer and E. Pick. Beitr. chem. Physiol u. Path., 1905, **7**, 331—381. Woch. f. Brau., 1906, **23**, 45—47.

THE authors have employed the refractive index as a physical measure for the study of the internal constitutional changes which accompany the splitting of complex bodies into simpler ones under the action of enzymes and acids. In all the cases in which the splitting of glucosides and polysaccharides by enzymes was studied, no change was observed in the refractive indices of the mixtures. Many of these reactions have been proved to be reversible equilbria, and, since the sum of the refractive indices of the products is equal to the refractive index of the original substance, it is concluded that no fundamental alteration in the structural relations of the atoms takes place. Similarly, the splitting of the bodies of this class, by means of acids, is not accompanied by any change in their refractive indices until the reactions have proceeded so far that secondary changes have occurred. The proteolytic action of pepsin also takes place without alteration of the refractive index, and is, therefore, of a simple nature. Trypsin, on the other hand, in its action on all albumins and albuminoid derivatives susceptible to tryptic digestion, causes an increase in the refractive index, and a more profound constitutional change is, therefore, indicated. This difference is regarded as being absolutely characteristic for the two typical proteolytic ferments. Digestion by papayotin is not accompanied by an increase in the refractive index. The splitting of albumin by the action of hydrochloric acid at a moderate temperature takes place without change of the refractive index, but the more profound change effected at the boiling temperature is accompanied by an increase in the refractive index. Lastly, it is found that the digestion or fermentation of meat bouillon and Witte's peptone by cultures of bacteria, such as the powerfully proteolytic species of Proteus, cholera vibrio and *B. coli comm.* is accompanied by a decrease in the refractive index, indicating that the processes of bacterial digestion differ in some essential particulars from those effected by pepsin, trypsin and acids.—J. F. B.

Carbon Dioxide; Action of ultra-violet light on moist and dry ——. S. Chadwick, J. E. Ramsbottom, and D. L. Chapman. Chem. Soc. Proc., 1906, **22**, 23.

BY the action of ultra-violet light on dry carbon dioxide, the authors have succeeded in partially decomposing it into carbon monoxide and oxygen. The conditions of the experiment made it impossible to decide what percentage of the oxygen was present in the form of ozone. If the carbon dioxide be moist there is no decomposition.

Departmental Committee on Royal School of Mines. Final Report, Feb., 1906. (Wyman and Sons, Fetter Lane, E.C.) Price 4d.

THE report of the Departmental Committee is signed by all the existing members—namely:—Mr. R. B. Haldane, K.C., M.P., Sir Francis Mowatt, Sir W. de W. Abney, F.R.S., Sir William S. Church, Mr. A. H. Leech, Sir Philip Magnus, M.P., Mr. Walter McDermott, Mr. F. G. Ogilvie, Lord Reay, Sir Arthur W. Rücker, F.R.S., Mr. Sidney Webb, Sir Julius C. Wernher, Sir William H. White, F.R.S., Mr. J. C. G. Sykes (secretary), and Mr. F. E. Douglas (assistant secretary).

The terms of reference, and the text of the conclusions and recommendations are given below:—

Terms of Reference.

To inquire into the present working of the Royal College of Science, including the School of Mines; to consider in what manner the staff, together with the buildings and appliances now in occupation or in course of construction, may be utilised to the fullest extent for the promotion of higher scientific studies in connection with the work of existing or projected institutions for instruction of the same character in the Metropolis or elsewhere; and to report on any changes which may be desirable in order to carry out such recommendations as they may make.

Conclusions and Recommendations.

76. The conclusions at which we have arrived are:—

(1) That the position of this country makes further provision for advanced technological education essential.

(2) That the students, by whose advanced technological education the nation would profit, are not actually obtaining it to the extent which is desirable, and that this is due to:—

(*a*) The lack of facilities for instruction in certain important subjects;

(*b*) The absence of such co-ordination among existing institutions of technological education as would permit the concentration of the more advanced courses in a limited number of institutions;

(*c*) An insufficient appreciation, especially on the part of employers, of the value of such education.

(3) That the opportunities for research in our technological institutions are inadequate to the industrial needs of the Empire, owing not to any want of ability on the part of the professors, but to the fact that much of their time is frequently absorbed in the giving of comparatively elementary instruction in Pure and Applied Science.

(4) That in any institution in which the highest technological education is given, the equipment should be adequate for the purpose, and the staff should include, at the head of the several specialised branches of the work, men of the first rank in their profession.

77. From this point of view the recommendations which we have the honour to submit in reply to our Terms of Reference may be summed up as follows:—

That the present combination of conditions at South Kensington points to the desirability of so utilising the resources there available, and of making additions to these, as to form on that site an institution of the highest standing, an institution which, with the staff, equipment, and students that it will command, would go far towards remedying the above-mentioned defects.

78. The remainder of our Report will show the manner in which we propose that effect should be given to the view thus summarised, and will take up the threads of

the scheme at the point at which our Parliamentary Report (Cd. 2610), of the 20th February last, left them.

79. It will be remembered that in that Report we inquired whether the Board of Education were in a position to inform us (1) that, if it were found possible to establish a scheme such as we had sketched in outline, they would be willing to allow the Royal College of Science (including the Royal School of Mines) to be brought into it under a common government and administration; and (2) that the existing Government contribution to the support of these institutions would be continued under the new conditions on the scale already made necessary by the provision of the new laboratories of the Royal College of Science.

80. We print in Appendix I. the answers which we have received from the Board of Education to these inquiries. It will be seen therefrom that the Board have replied to the first of these questions in the affirmative, and that, in reply to the second, the Government have intimated that they will be prepared to bring the Royal College of Science and Royal School of Mines, including the new laboratories, into a scheme framed on lines approved by the Board of Education, in accordance with this Report, and to make a grant of £20,000 per annum in respect of the cost of staff and of the laboratory expenses, with provision in addition for certain other minor expenses.

81. The favourable disposition of the Government has greatly strengthened our position, and enabled us to obtain the support and co-operation which we consider necessary to ensure the success of the scheme described generally in our Preliminary Report.

82. The gift of a capital sum in excess of the *minimum* referred to in Section III. of that Report has been secured.

83. The Commissioners of the 1851 Exhibition are prepared, if satisfied with the scope and constitution of the new institution, to place at the disposal of its governing body the unoccupied portion of their estate at South Kensington.

84. The Council of the City and Guilds of London Institute have indicated their willingness to bring the Central Technical College into a scheme to be framed to their satisfaction on the general lines we are able to recommend in this Report.

85. We attach the highest importance to the co-operation of the London County Council, as the local education authority, and with regard thereto the most cordial assurances were given at an early stage of the movement. The Council, on the 27th July, 1903, received a report from its General Purposes Committee upon the proposal contained in the letter which Lord Rosebery had a short time previously addressed to the Chairman of the Council—a proposal, the essential features of which are incorporated in our scheme and passed a resolution expressing "its high appreciation of the important proposal," and its welcome of "the establishment of further provision in London for advanced technological teaching and research." It further resolved to place on record its opinion that, subject to certain conditions being fulfilled (about which we may say we do not anticipate any difficulty), the Council would be well advised, when the time came, to contribute a sum not exceeding £20,000 per annum towards the maintenance of the institution.

86. In our opinion a sufficient maintenance fund is assured, at any rate, to justify a commencement, if not to carry out the scheme we have in view as fully as we hope may be possible hereafter.

87. As stated in our Preliminary Report, we have inquired into the working of the Royal College of Science and the Royal School of Mines, but we have done so with a definite end in view. We think it appears from the answers we have received from the Board of Education to the questions we ventured to ask in that Report, taken in conjunction with the terms of reference, that it is the desire of His Majesty's Government that the staff of the Royal College of Science, including the Royal School of Mines, together with the buildings and appliances now in occupation or in course of construction at South Kensington, should be utilised to the fullest extent for the promotion of higher scientific studies in connection with the larger scheme which we endeavoured to sketch in outline in our Preliminary Report. We have now to make, so far as appears to us possible, recommendations with regard to the essential features in the constitution and purposes of the new institution which we propose should be created, and with regard to the position of the several bodies brought with it under a common government and administration.

88. The main object is the establishment, at South Kensington, of an institution or group of associated Colleges, of Science and Technology, where the highest specialised instruction should be given, and where the fullest equipment for the most advanced training and research should be provided, in various branches of science, especially in its application to industry, for which no sufficient provision already exists elsewhere. The number of the departments will be limited by the resources available, and at first a selection will have to be made among them, but they may be increased almost indefinitely as additional means are provided, and new applications of science to the arts and industries are discovered. The scale on which the departments are established should be capable of gradual expansion with the increase in the number of students, fitted by preliminary education, to take advantage of the teaching and training contemplated.

89. The scheme should, in the first instance, and subject to necessary adjustments, include the work of the Royal College of Science, the Royal School of Mines, the Central Technical College, and departments to be established on the additional site at South Kensington.

90. Such being the scope of the new institution, it is necessary that we should make recommendations with regard to the composition and functions of its governing body, and the question at once arises what should be the relation of the new institution to the University of London. On this question it is necessary to premise that we are agreed that it is desirable that the new institution should be established immediately, and that its organisation should proceed without delay, and there is substantial agreement among us that for this purpose a governing body of the character sketched in a subsequent paragraph should be at once appointed with power to take immediate action. We wish, however, to put in the forefront of our recommendations under this head a proviso that they should not be regarded as in any way intended to prejudice the future settlement of the question of the relation between the new institution and the University. This is a question on which divergent views are held. It is contended, on the one hand, that the constitution we recommend for the immediate future should not be a merely temporary one, but that the new institution should be permanently independent of University control; and, on the other hand, that the new institution should pass, as soon as may be, under the control of the University, the character of the University, and the composition of its Senate, being changed to such extent as may be found necessary for this purpose.

91. We append a brief statement of arguments which have been put forward in support of these two views.

92. For the first view it is said:

"It is assumed that, whatever may be the subsidiary purposes of the new institution, its principal purpose must be to afford a two years' course of advanced study, linking science with investigation, production and manufacture, to students of, say, nineteen years of age and upwards, who have received elsewhere a good general education, and have passed in addition through the equivalent of a two years' systematic training in science, whether at the new institution itself or elsewhere. Such an institution, while it will make for the general intellectual development of its students, will have their preparation for the work of life as its dominant aim. It must therefore maintain close contact with current practice in the industries of the Empire, and, although it will not overlap these, the transition from the school to the world of work must be easy and natural. Industrial and commercial conditions are constantly altering, the character and relative importance of manufacturing processes, and even of entire sections of national activity are subject to unforeseen variation. An institution which is to keep touch with these interests, must be correspondingly elastic. Its organisation must be free from

all impeding trammels founded upon experience of the well-tried and comparatively little-changing track of an education regulated, and rightly regulated, by other aims. It must be free to adapt itself, its staff arrangements, and its methods of teaching to the conditions of the time. Its constitution must place the responsible control in the hands of men with a continuing knowledge of affairs and of the great producing activities of the Empire, and its governors must be in a position to govern with a single eye to the fitness of the institution for its proper function.

"These conditions of success appear to exclude the proposition that the control of the institution should be vested in a University. It has been suggested that some modification might be made for the purpose in the composition of the Senate of the University of London; but changes introducing such control and organisation as are here indicated would be so radical as to be inconsistent with the prevailing British conception of a University, and if applied to London University might endanger its usefulness in many of its existing functions which are of vital importance to the successful accomplishment of its essential objects. A system of control and organisation common to the new institution and the University could not be formulated without such compromises as would seriously impair the efficiency of both.

"Moreover, students for advanced courses of study in the new institution should be drawn from all parts of the Empire. It should, in fact, be an Imperial College of Technology, admission to which should be sought by men trained in the Universities and Technical Colleges at home and in the Dominions beyond the sea. Freedom from subordination to any existing University would enhance its attraction for the ablest students whose preliminary training had been obtained elsewhere, and would indicate its distinctive character as an Imperial College. Students would be free to take degrees at London University or other Universities, in addition to the College Diplomas.

"London University has special obligations laid upon it in connection with the London district, and must continue to fulfil them. It cannot claim any peculiar right to provide for Imperial needs. On all these grounds it is undesirable to attempt amalgamation of the new institution with London University."

93. For the second view it is said:—

"(1) Modern opinion, at home and abroad, is in accord that degrees should be given for advanced technological education.

"In this country, if it is possible to infer a settled policy from recent and numerous precedents, it appears that such degrees should be given by Universities. Not to mention recent developments at the older Universities, the power of conferring degrees for advanced instruction in technology has been given by each of the five University Charters granted within the last five years, as well as to the University of London, when it started on its new career.

"Since it is recommended that the new institution shall be (as each of its existing component parts already is) a School of the University of London, the Report contemplates no change in the degree-giving power of the University. There would, however, evidently be danger of friction between the University and a powerful School if each were regarded by the other as external to itself.

"Nor is it desirable that the great engineering societies should have a large share in the management of the chief Engineering College in the Metropolis, without having a corresponding share in settling the conditions under which degrees are given, and without being also associated with the management of other London Schools of Engineering of University rank.

"These objects could be attained if all these institutions were under a common control (which could hardly be other than that of a modified Senate of the University), and if the bodies, which on the alternative scheme would be interested only in the new College, were given such representation on the Senate as would enable them to exert a powerful influence in deciding the terms on which the degrees in Engineering were given, and in controlling all Engineering education of University rank in London, whether established at South Kensington or elsewhere.

"(2) The University has already prepared the way for such a solution of the problem. The Senate in a letter addressed to the committee has expressed its willingness that its numbers should be increased if the new College were administered by, or under the control of, the University. On that condition, too, University College appears willing to consider either the proposal that its Engineering Department should be moved to South Kensington, or that it should have special relations to the new College. Difficulties due to the existence of separate interests have been and are being diminished. Firstly, the University College London (Transfer) Act, 1905, will make the College and its resources the property of the Senate in September next; and secondly, King's College has approached the University with the expression of a desire for the establishment of closer relations between them, and the negotiations are proceeding satisfactorily.

"It would be a very serious step to check a spontaneous movement, which is thus healing the divisions and rivalries that have hindered the progress of University education in London for three quarters of a century, by reverting to the principle of dual or multiple control which, as experience has shown, tends neither to economy nor efficiency.

"(3) As to the question whether a University is the proper body to exercise control over an Imperial Technical College it must be observed:—

"Firstly, that one of the 'purposes' of the University of London approved by Parliament is to 'hold forth to all classes and denominations both in the United Kingdom and elsewhere without any distinction whatsoever an encouragement for pursuing a regular and liberal course of education' (Statutes, Section 3). The University is not, therefore, a local body only. Its energies were not intended to be confined, and are, in fact, not confined, to the United Kingdom or to London.

"Secondly, that the proposal to give ultimate control to the University is bound up with that for the appointment of a Royal Commission, which would probably give to the representatives of Engineering on the Senate, adequate powers to deal with the conditions on which degrees in that subject are conferred, and to secure the requisite flexibility in the conduct not only of the new College but of the whole faculty of Engineering.

"Thirdly, that an Imperial institution which throws its doors open to all must be largely local in character. Nay, it should be so, if the mingling of British and Colonial students, which it is one of the main objects of Imperial Education to secure, is to be attained. Further, a successful local institution of the first rank must become in part National, Imperial, and even International. It is, in fact, impossible to draw a clear line of demarcation between Imperial and Local Education. An Imperial institution must have a strong local basis, and the effect of its creation on local education is a matter of primary importance. An attempt to establish side by side two systems, one Imperial and the other local, would only lead to confusion."

94. We do not consider that the establishment of the new institution should be delayed pending a decision between these two views, or that the general lines of its organisation (except, possibly, as respects the Governing Body) should be regarded as other than permanent. If changes can be made in the character and constitution of the University which will make it desirable to amalgamate the two institutions, we should wish to see such modifications made, and an amalgamation effected accordingly, and we venture to suggest that a Royal Commission should be appointed to consider what these changes should be.

95. Meanwhile, for the reasons we have already given, and subject to the proviso we have already made, we recommend that a Governing Body should be established consisting of forty members appointed as follows:—

Six by the Crown;

Four by the Board of Education;

Five each by the University of London, the London County Council, and the Council of the City and Guilds of London Institute;

Four by the teaching staff of the new institution;
Two by the Commissioners of the Exhibition of 1851;
One each by the Royal Society, the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Institution of Electrical Engineers, the Iron and Steel Institute, the Institution of Naval Architects, the Society of Chemical Industry, the Federated Institution of Mining Engineers, and the Institution of Mining and Metallurgy.

96. The Governing Body should have the general management, direction and administration of the new institution, which should be established in the first instance as a School of the University of London.

97. For the purposes of the new institution the Governing Body should have the entire disposal of the accommodation provided by the Royal College of Science, including the buildings in course of construction at South Kensington, the Central Technical College, and all buildings which may be erected on the additional site at South Kensington.

98. The site and buildings of the Royal College of Science including the buildings in course of construction should either remain the property of His Majesty's Government or be transferred to the Governing body of the new institution, as His Majesty's Government may determine.

99. The site and buildings of the Central Technical College should, if and so long as they desire it, remain the property of the City and Guilds of London Institute, who should provide for their maintenance and repair.

100. The Governing Body should be incorporated, and subject to such special provisions as may be made by their instrument of incorporation they should receive and expend fees and other funds which may be assigned to the purposes of the new institution, they should appoint the professors and the other members of the staff, they should determine the departments and subjects of instruction, they should control the arrangement of the courses of instruction, and the award of diplomas, and they should make provision for the protection of students now in the constituent institutions and of the existing diplomas. Further, in each of the departments of the new institution the Governing Body should appoint a Board, not necessarily consisting of members of their own body, and including members of the teaching staff and persons with practical experience of industrial requirements, to give expert advice with regard to such particulars connected with that department as the Governing Body may refer to them.

101. We recommend that it be an instruction to the Governing Body to enter into negotiations with the University of London, with King's College, and pending its actual incorporation, with University College, with regard to the co-ordination of the engineering work of these Colleges with that of the new institution. If, for the purpose of carrying out such co-ordination, funds are needed, either for transferring the Engineering Departments of one or both of these Colleges to South Kensington, or for carrying on at these Colleges work of an advanced type which would otherwise be done at South Kensington, or in aid of any other arrangement for that purpose to which the Governing Body may agree, we recommend that the Governing Body be authorised to incur such reasonable expenditure as may in their opinion be necessary. Subject to such arrangements, we recommend that instruction in the higher branches of technology should, as far as possible, be concentrated at South Kensington. In the establishment of new departments we do not think it will be possible at present to go much beyond the various branches of engineering, with mining and metallurgy, though we hope provision may be made later for other subjects. We think the principal technical and engineering societies should be consulted as to the departments most requiring development and expansion, and as to the number of students for whom it is desirable to make provision in each department. In view of the character of the subjects which will, it may be expected, predominate on the South Kensington site, it must, we think, before long become a question whether the Biological Department of the Royal College of Science shall be retained there. As soon as this question becomes ripe for settlement the provision to be made for that department will be a matter for negotiation.

102. In our Preliminary Report we indicated the principal subjects which should, in our opinion, either at once or in the early future, be within the purview of the institution, and gave illustrations of the kind of higher or more specialised applications of these subjects, some of which we suggested should be dealt with. We do not think we can usefully offer more precise recommendations than are made in that Report as to the priority in which the different branches of study should be undertaken, believing that this is a matter which will be best left to the Governing Body.

103. We think, however, that it may be found possible, even in the immediate future, to make arrangements for the establishment of departments dealing adequately with the greater number of the special sections of applied science named. Thus it would seem that certain of these departments might be accommodated in the buildings of existing London institutions, while, for others, special accommodation would fall to be provided at once in the first additions to the buildings already available on the South Kensington site. For example, in view of the character and standard of the work now carried out by the Central Technical College, we think prominence should be given in the new institution to certain specialised developments of mechanical and electrical engineering.

104. We have already reported that we think a fully-equipped Central School of Mines should be maintained, providing a full course of instruction in mining and metallurgy, especially in the mining and metallurgy of metals produced in India and the Colonies, but not found in workable quantities in the United Kingdom. This would constitute one department of the new institution. In this, as in the other departments, care should be taken that the specialised and advanced instruction is organied with due regard to provision already made elsewhere—for example, it would probably be undesirable to include provision for advanced treatment of the metallurgy of iron and steel.

105. It should be borne in mind that the traditions and prestige of the Royal School of Mines and the Associateship of that school are valuable assets, and we think care should be taken to preserve those traditions and that diploma.

106. We think the specialised course of mining should be of two years' duration, in which the teaching should be restricted to technical and advanced instruction. Special courses of mining and metallurgy should be provided for those students who are subsequently to be engaged in mining and metallurgy respectively, but all such students should receive, as far as possible, concurrent instruction in both mining and metallurgy.

107. In our opinion accommodation should be provided in this department for 100 to 120 fully-qualified students, *i.e.*, fifty or sixty entries in each of the two years contemplated, so that forty to fifty students might be expected to pass out each year after successfully completing the course.

108. Vacation work under the guidance of school authorities, in districts where practical work is conducted, is a great and valuable feature of American and Canadian Schools of Mines. We think it would be advantageous for students of the Royal School of Mines to have one short period of practical mine surveying and of mining work generally in a metalliferous mine, and another similar period of experience of the work of a coal mine. For while we do not recommend that the Royal School of Mines should specialise in coal mining as in metalliferous mining, we believe that such experience, in a department of mining in which Great Britain is pre-eminent, would afford most valuable educational opportunities, even for mining students whose future work was to be metalliferous mining. From the evidence before us we think that it might be of advantage that the arrangements for these courses of vacation work should be made through such institutions as the Camborne Mining School and the Wigan Mining College respectively.

109. One of the Sub-committees which we have had occasion to appoint from time to time in the course of our deliberations was charged with the consideration of the curriculum, accommodation, and appliances suitable for the Royal School of Mines, and we submit in Appendix

VIII. the report which was made to us by that Sub-committee.

110. At first, at any rate, we think preliminary training should be given in the new institution. But while, on the one hand, we do not recommend that admission to the higher technical courses should be limited to students who obtain their preliminary training there, on the other hand we think that, both as regards the general education of the students admitted and the character of the teaching provided, this preliminary branch of the new institution should be organised with the definite intention of preparing thoroughly suitable candidates for admission to the advantages of the higher instruction which it is the principal object of the new institution to afford.

111. No student should be admitted to any specialised technical department who has not received, either in the new institution itself or elsewhere, an adequate training of a technical and scientific character such as should be common to every branch of engineering. He should have spent two years on a course of instruction in science such as he could obtain in a well-organised college or technical institution, after having reached the standard of general education usually marked by University matriculation. An examination test should be imposed on all candidates for admission to the higher departments, except in the case of students who show, by some recognised qualification, that they have received the necessary preliminary training, and when there are more candidates for admission to a particular department than can be received the best should be selected on a competitive basis.

112. The preliminary training to be given in the new institution should be of the kind which has just been referred to. It should consist of a course of two years' instruction in science, technology, and engineering, of such a character as the Governing Body consider the most suitable preparation for the specialised courses, and it should be, in the main, common to all students proceeding to advanced instruction in any department. We have already indicated our opinion that students who have not attained a certain standard of general education are not fitted to obtain the fullest advantage from the specialised instruction of the higher departments. We, therefore, think that evidence of this should be required before admission to the preliminary department.

113. With regard to educational arrangements we recommend that, subject to reservations made by any constituent institution or co-operating body which may stipulate for the right to enter students under prescribed conditions, students should enter not for any one of the constituent institutions but for the new institution as a whole, with a view to following out courses to be arranged by the Governing Body.

114. The professors of the constituent institutions should be regarded as professors of the new institution.

115. There should be a principal officer of the new institution, who should be responsible to the Governing Body for the supervision of education and discipline in all the constituent institutions.

116. It must, in our opinion, be left to the Governing Body to work out the scheme in detail and to make statutes and regulations for the new institution in general accordance with our proposals.

117. We desire, in bringing this Report to a close, to record our deep indebtedness to Mr. Sykes, our Secretary, for the devotion and knowledge which he has brought to bear on our task. Alike in his work here throughout the two years during which the Committee has been sitting, and in the investigation which he has conducted for us abroad, he has displayed the utmost zeal and discretion.

118. To Mr. Douglas, also, our Assistant Secretary, we are under much obligation for the qualities he has shown, for the large mass of material which he has collected for us, and for the amount of work which he has put into the discharge of his duties.

The signatures of Mr. Walter McDermott and Sir William H. White are subject to a statement defining the position of the proposed Royal Commission to consider what changes should be made in the character and constitution of the University of London in order that the new institution may be amalgamated therewith. The signatories of this statement express the opinion that it is vital to the success of the new institution that its organisation and equipment for the part it is to play in technical education should be entrusted, for a *minimum* period of five years, to a special governing body, such as is recommended in the report; that the uninterrupted action of that body should be assured during this period; and that inquiry by Royal Commission or otherwise should be deferred until experience has been gained in actual working.

Lord Reay and Sir Arthur Rücker add a memorandum in which they record their opinion that it is desirable in the interests of higher education and of the new institution that steps should be taken as soon as possible to incorporate it in the University of London.

Trade Report.

BRITISH INDIA; SCHEDULE IV.—IMPORT TARIFF.

Bd. of Trade J., Feb. 8th, 1906, 271—273.

No.	Names of Articles.	Per	Tariff valuation.	Duty.
	CHEMICALS, DRUGS, MEDICINES, NARCOTICS, AND DYEING AND TANNING MATERIALS.		R. a.	Per cent.
10	Chemical products and preparations—			
	Acid, sulphuric	lb.	0 1½	5
	Alkali, Indian (sajji-khar)	cwt.	2 0	,,
	Alum	,,	4 8	,,
	Arsenic (other than European)	,,	23 0	,,
	,, (China mansil)	,,	19 0	,,
	,, other sorts	—	*ad val.*	,,
	Bicarbonate of soda	cwt.	6 0	,,
	Copperas, green	—	*ad val.*	2½
	Explosives, namely, blasting gelatin, dynamite, roburite, tonite, and all other descriptions, including detonators and blasting fuse.			
	Sal ammoniac	cwt.	30 0	,,
	Sulphate of copper	,,	17 8	,,
	Sulphur, (brimstone), flour	,,	5 8	,,
	,, ,, roll	,,	5 4	,,
	,, ,, rough	,,	5 0	,,
	All other sorts of chemical products and preparations, including saltpetre, borax, grape sugar and glucose, but excluding nitrate of soda, chloride of potassium, sulphate of ammonia, sulphate of potash and kainit salts, which are free.	—	*ad val.*	,,
11	Drugs, medicines, and narcotics—			
	Banslochan (bamboo camphor)	lb.	0 4	,,
	Brimstone (amalsâra)	cwt.	16 0	,,
	Camphor, refined, cake	lb.	2 0	,,
	,, partially refined, cake, in blocks of about 13 lb.	,,	1 10	,,
	Camphor, crude, in powder	,,	1 8	,,
	China root (chobchini), rough	,,	9 0	,,
	Cocaine	—	*ad val.*	,,
	Quinine and other alkaloids of cinchona	—	—	free
	All other sorts of drugs, medicines, and narcotics, except opium	—	*ad val.*	5

New Books.

La Céramique Industrielle. Par Albert Granger, D. ès. Sc., Professeur de Chimie et de Technologie Céramique à l'Ecole d'Application de la Manufacture Nationale de Sévres. Gauthier-Villars, Imprimeur-Libraire. Quai des Grands-Augustins, 55, Paris, 1905. Price 17 Fr.

8vo volume, containing 627 pages of subject matter, and an alphabetical index. There is also a glossary of terms used in the industry with their meanings, also a table of contents. In the text are 179 illustrations. The subject matter is sub-divided and classified as follows:—I. Plastic Substances. II. Nonplastic Substances. III. Tests of Raw Materials, and Analysis of Pastes, Colours, &c. IV. Preparation of Raw Materials. V. Preparation of Pastes. VI. Moulding. VII. Drying and Furnacing. VIII. Baking the Wares. IX. Glazes, Enamels. X. Terra-cotta. XI. Refractory Products. XII. Crockery and Earthenware. XIII. Stone-ware. XIV. Porcelain. XV. Decoration. XVI. Importance of the Ceramic Industry.

Conversations on Chemistry. First Steps in Chemistry. By W. Ostwald, Professor of Chemistry in the University of Leipsic. Translated by Stuart K. Turnbull. Part II.—The Chemistry of the most Important Elements and Compounds. First Edition. John Wiley and Sons, New York, 1905. Price 8s. 6d. nett. Chapman and Hall, Ltd., London.

Small 12mo volume, containing 373 pages of subject matter with 32 illustrations. There are 45 chapters of subjects taken from inorganic chemistry, and chiefly relating to the principal elements and compounds. The treatment of the matter is by way of question and answer.

The Production of Aluminium and its Industrial Use. By Adolphe Minet. Translated, with additions, by Leonard Waldo, S.D. (Harv.). First Edition. John Wiley and Sons, New York, 1905. Price 10s. 6d. nett.

12mo volume, containing 256 pages of subject matter with 57 illustrations, and alphabetical indexes of subjects and authors' names. The subject matter is classified as follows:—Part I.—Processes for the Production of Aluminium. A. Chemical Methods of Producing Aluminium. B. Electrochemical Methods of Producing Aluminium. Part II.—Aluminium and its Alloys, Methods of Working and Uses. A. The Aluminium Industry. B. Aluminium and its Alloys. C. Working of Aluminium. D. Uses of Aluminium. Appendix—Supplementary Notes.

Le Blanchissage et l'Apprêt du Linge. Louis Vérefel. Aux Bureaux de la Revue., 64, Chaussée d'Antin, 1906. Price 3 frcs.

12mo volume, containing 173 pages of subject matter with 73 illustrations, and a table of contents. The subject matter is classified thus:—Part I. Bleaching. 1. Nature of Articles Bleached. 2. Theory of Bleaching. 3. Chemical Products used in Bleaching. Bleaching by Cleansing Agents. II. Industrial Bleaching. Part II. Finishing.

Electric Power. What it is, and what it can do. By Alfred W. Marshall, M.I.Mech.E., &c. Perceval Marshall and Co., 26-29, Poppin's Court, Fleet Street, E.C., 1906. Price 3d.

Pamphlet, 12mo size, containing 41 pages of subject matter, including a glossary of "Every-day Electrical Terms Simply Explained."

JOURNAL OF THE

Society of Chemical Industry.

No. 5.—Vol. XXV. SUPPLEMENT. March 15, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Dr. Edward Divers, F.R.S

GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. Full particulars will be announced later.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

INDEX FOR 1905.

The Index for 1905 is in the press and will be ready for issue with the March 31st number to those members entitled to receive it.

LONDON SECTION.

The next meeting of the London Section will be held at the Chemical Society's Rooms, Burlington House, Piccadilly, on Monday, April 2nd, when Mr. E. J. Watkins will read a paper on "The Ropiness in Flour and Bread, and its detection and prevention."

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

IMPORTANT NOTICE.

Arrangements have been made with Messrs. Thos. Cook & Son for an inclusive charge of £17 per person for the journey. This will include first-class return tickets to Rome, leaving London on the 23rd April by the 2.20 p.m. service, *via* Boulogne and St. Gothard route, and arriving at Como at about 2 p.m. on the 24th; a steamer trip from Como to Bellaggio and back, departure from Como on Wednesday morning, the 25th, arriving in Rome at 11 p.m. the same day. The charges further include dinner *en route* on April 23rd, breakfast on arrival at Bâle and luncheon *en route* on the 24th, steamer trip, dinner and hotel at Como, breakfast, luncheon, and dinner on the 25th, first-class hotel accommodation, including breakfast, at Rome during seven days' stay; also transfers between station and hotel at Rome on arrival, the necessary fees to railway and hotel servants, and the services of a competent courier on the outward journey up to the arrival at the hotel in Rome. The tickets are available for return at any time within 25 days, and members are at liberty to return by the Mont Cenis route, provided that they notify this intention when applying for the tickets. Sleeping car accommodation from Boulogne to Bâle will be provided at an extra cost of 15*s.* 10*d.* for each person. For those who desire full board and lodging in Rome, the inclusive charge will be £18 15*s.*

Since at the time of the Congress all railways and hotels will be full, it is necessary to give Messrs. Cook ample notice, and therefore applications for tickets should be made at once, but not later than the 22nd

March, to the General Secretary, Charles G. Cresswell, Palace Chambers, Westminster, S.W. Should the requisite minimum number of 30 applications be received, each applicant will be required to deposit the sum of £8, which he will forfeit should he abandon the journey.

Changes of Address.

Alston, R. A., l/o Knights; c/o Glencairn Main Reef G. M. Co., P.O. Box 191, Germiston, Transvaal.
Anspach, Dr. R., l/o Sweden; 25, Cleveland Road, Manningham, Bradford.
Arnott, John S., l/o Cifuentes; Moros 42, 2º, Gijon, Spain.
Baruch, Edgar, l/o San Francisco; c/o Alta California Beet Sugar Co., Hamilton, Glenn Co., Cal., U.S.A.
Bhattacharyya, H. P.; all communications to Gun and Shell Factory, Cossipore, India.
Bourne, L. M., l/o Chelsea, Mass.; 65, Strong Place, Brooklyn, N.Y., U.S.A.
Bowen, W., l/o Oleander; R. R. I., Fowler (Rural Route), Fresno Co., Cal., U.S.A.
Clare, Henry, l/o Newgate Street; Hepscott, Morpeth, Northumberland.
Crowther, J., l/o Adelaide; 5, Granby Terrace, Hillhead, Glasgow.
Dent, Dr. Frankland, l/o Medical Dept.; Govt. Analyst's Laby., Singapore, S.S.
Enright, B., l/o Fordwick, Va.; South Bethlehem, Pa., U.S.A.
Fogetti, L., c/o Allen B. Wrisley (not Winsiey) Soap Co., Chicago, Ill., U.S.A.
Fuller, H. C., l/o West Medford; 90, William Street, New York City, U.S.A.
Green, G. F. Dudbridge, l/o Gainsborough Road; Lea Conservancy Road, Hackney Wick, N.E.
Heathcote, H. L., l/o St. Nicholas Street; Warwick Avenue, Earlsdon, Coventry.
Hunter, Prof. Matthew, l/o Rangoon; Cowside, Settle, Yorks.
Hutchinson, E. George, l/o Barnsley; Gasworks, Stockport.
Lynne, Miss Mary S., l/o Pittsburgh; 235, Second Avenue, New York City, U.S.A.
McKechnie, R. D., l/o Glasgow; Productos Quimicos de Huelva, Sociedad Anonyma, Huelva, Spain.
Masury, Fred. L. M.; all communications to Lock Box 144, Sharon, Pa., U.S.A.
Morison, S. L., l/o New York; c/o John Brett, 8, Lendal, York, England.
Mosbaugh, F. R., l/o Canada; c/o Heald Extract Co., Lynchburg, Va., U.S.A.
Oberländer, Dr. Otto, l/o Victoria Park; 21, Portland Crescent, Plymouth Grove, Manchester.
Peffer, Harry C.; all communications to c/o Pittsburgh Reduction Co., East St. Louis, Ill., U.S.A.
Queiroz, L. M. Pinto de; all communications to Caixa 255, Sao Paulo, Brazil.
Rust, Robt. R., l/o Depue; 1315, Fourth Street, Peru, Ill., U.S.A.
Saxe, Sigmund; all communications to 107, Manhattan Avenue, New York City, U.S.A.
Shields, Dr. John; Journals to Minas de Rio Tinto, Prov. de Huelva, Spain.
Shoffstall, A. S.; Journals to 307, Morris Street, Woodbury, N.J., U.S.A.
Short, Andrew; Journals to 24, Simpson Street, Newcastle-on-Tyne.
Singer, Ignatius, l/o Horsforth; 3, Parkfield Road, Manningham, Bradford.
Skowronski, S., l/o Perth Amboy; c/o American Smelting and Refining Co., Maurer, N.J., U.S.A.
Smith, Edgar B., l/o Silvertown; Box 599, Sydney, Cape Breton, Canada.
Smith, R. W.; all communications to P.O. Box 85, Knights, Transvaal.
Southerden, F., l/o 56; 49, West Grove Road, Exeter.
Spayd, C. H., l/o Philadelphia; Fernwood P.O., East Lansdowne, Delaware Co., Pa., U.S.A.
Steiger, Geo., l/o Geological Survey; Cosmos Club, Washington, D.C., U.S.A.
Thomas, Jas. E., l/o Germiston; P.O. Box 53, Krugersdorp, Transvaal.
Wainwright, Dr. J. H., l/o Front Street; 60, Wall Street, New York City, U.S.A.
Wakefield, Wm. C.; Journals to c/o Savile Town Chemical Co., Ltd., Mill Street East, Dewsbury.
Woodside, T. F., l/o Carteret; The Warner Chemical Co., 141, Broadway, New York City, U.S.A.
Wildman, A. J., l/o Stroatfield Avenue; 133, Central Park Road, East Ham, E.

Member Omitted from List.

1904. Stevens, Edgar B., 688, Seventh Street, Buffalo, N.Y., U.S.A., Chemist (Wood Products Co.).

Deaths.

Donald, Jas., 96, Anerley Park, Anerley, S.E.
Littlewood, Dr. Jas. B., Chief Examiner in Chemistry, Patent Office, Washington, D.C., U.S.A.
Lyte, F. Maxwell, 17, Mentone Mansions, Fulham Road, London, S.W. March 4.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 3432. Passburg. Apparatus for drying pulverised, granular, and like material *in vacuo*.* Feb. 12.
,, 3443. Lee. Apparatus for boiling liquids. Feb. 12.
,, 3458. Mower and Bassett. Drying kilns. Feb. 12.
,, 3542. Hoddinott. Centrifugal separators. Feb. 13.
,, 3809. Clapham and Clapham. *See under* II.
,, 3954. Adams and Cannon. Kilns. Feb. 17.
,, 4245. Grossmann. Preventing corrosion of metallic vessels in the evaporation and storing of liquids. Feb. 21.
,, 4419. Lehmann. Drying substances containing volatile matters. Feb. 23.
,, 4473. Mills (Hendricks). Process of separating materials containing an admixture of moisture.* Feb. 23.
,, 4547. Cartwright. Surface apparatus for condensing, evaporating, or the like. Feb. 24.
[C.S.] 4271 (1905). Binder. Centrifugal extractors. Feb. 28.
,, 5663 (1905). Hinze. *See under* XVI.
,, 6185 (1905). Mower. Treating fumes escaping from furnaces for the recovery of valuable constituents. Feb. 21.
,, 6916 (1905). Brown. Distilling and condensing apparatus. Feb. 21.
,, 8814 (1905). Johnson (Matcham). Coolers for powdered or granular material. Feb. 28.
,, 10,617 (1905). Rudge-Whitworth, Ltd., Pugh and Heathcote. Method of ascertaining the temperature of heated articles. Feb. 21.
,, 10,875 (1905). Aktiebolaget Separator. Centrifugal separating apparatus. Feb. 28.
,, 13,492 (1905). Brewtnall. Apparatus for cooling and heating. Feb. 21.

[C.S.] 17,457 (1905). Warren. Rotary kilns. Feb. 28.
,, 19,209 (1905). Lake (Aktiebolaget Separator). Centrifugal separators. Feb. 21.
,, 24,186 (1905). Ray. Evaporating apparatus. Feb. 21.
,, 25,871 (1905). Messinger and Popper. Drying process and apparatus therefor. Feb. 21.

II.—FUEL, GAS, AND LIGHT.

[A.] 20,445A (1905). Wesselsky. Gas generator. Feb. 21.
,, 3417. Schatz. *See under* XXIII.
,, 3456. British Thomson-Houston Co., Ltd. (Gen. Electric Co.). Filaments for incandescent electric lamps. Feb. 12.
,, 3509. Iseki. Filament for incandescent lamps.* Feb. 13.
,, 3570. Winand. Elimination of carbon dioxide from the combustion products of internal combustion engines. [Ger. Appl., Feb. 18, 1905.]* Feb. 13.
,, 3637. Seymour. Coke ovens. Feb. 14.
,, 3684. Just, Hanaman, Landesberger, Salzmann, and Verein. Elektricitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. Feb. 14.
,, 3695. Forbes. Preparation of calcium carbide. Feb. 14.
,, 3730. Parker. Manufacture of coal gas and apparatus therefor. Feb. 15.
,, 3809. Clapham and Clapham. Apparatus for extracting tarry or like substances from gases. Feb. 16.
,, 3816. Lynde. Apparatus for generating gas. Feb. 16.
,, 3870. Pistorius. Manufacture of lighting gas and dense coke from coal dust.* Feb. 16.
,, 3998. Prout. Manufacture of peat fuel. Feb. 17.
,, 4077. Müller. Power gas producers.* Feb. 19.
,, 4081. Just, Hanaman, Landesberger, Salzmann, and Verein. Elektricitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. Feb. 19.
,, 4119. Ingrey, Bartlett and Maclure. Production of acetylene. Feb. 19.
,, 4230. Holmes, Holmes and Cameron. Apparatus for extracting tar from illuminating gas.* Feb. 20.
[C.S.] 24,242 (1904). Arzt and Baron. Gas for illuminating and heating purposes. Feb. 21.
,, 27,397 (1904). Central Torfkohlen Ges. Manufacture of peat fuel. Feb. 28.
,, 4917 (1905). Whitfield. Suction gas producer plant. Feb. 21.
,, 4921 (1905). Buchanan. Gas furnaces for charcoal and like kilns. Feb. 28.
,, 11,949 (1905). Just, Hanaman, and Verein. Elektricitäts A.-G. Manufacture of filaments for electric incandescent lamps. Feb. 21.
,, 21,447 (1905). Woodall and Duckham. Vertical retorts for the destructive distillation of coal. Feb. 28.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 3892. Thompson (Soc. d'Eclairage et de Chauffage par les procédés A. Guy). Apparatus for the vaporisation of petrol and other oils for the production of carburetted air.* Feb. 16.
,, 4427. Coulson. Process of solidifying tar.* Feb. 23.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 3449. Arnold, Fox, Scott and Roberts. Manufacture of nitro compounds. Feb. 12.
,, 3506. Hirschberger, Hoffa, and Levinstein, Ltd. New colouring matter and the production thereof. Feb. 13.
,, 4097. Ransford (Cassella und Co.). New sulphur colours and process for making same. Feb. 19.
[C.S.] 5449 (1905). Chem. Fabr. vorm. Weiler-ter-Meer. Manufacture of a yellow sulphur dye. Feb. 21.
,, 11,066 (1905). Meyenberg, Allpass, and Clayton Aniline Co., Ltd. Manufacture of sulphur colouring matters. Feb. 28.
,, 13,804 (1905). Ransford (Cassella und Co.). Manufacture of polyazo colours. Feb. 21.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 3549. Lake (Linkmeyer). Manufacture of artificial silk.* Feb. 13.
,, 3566. Linkmeyer. Recovery of oxide of copper in the manufacture of artificial silk. [Belg. Appl., April 5, 1905.]* Feb. 13.
,, 3709. Kay and McGregor. Printing textile fabrics. Feb. 15.
,, 4073. Meister, Lucius und Brüning. Manufacture of ketone sulphoxylates. [Ger. Appl., Sept. 30, 1905.]* Feb. 19.
,, 4121. Keffel and Meinel. Manufacture of a waterproof washable material of velvety appearance.* Feb. 19.
,, 4461. Innes-Baillie. Process of degumming ramie and other grasses or fibres. Feb. 23.
,, 4569. Feder. Manufacture of moisture-proof fabrics.* Feb. 24.
,, 4595. Zürcher. Method for painting fabrics.* Feb. 24.
,, 4597. Lilienfeld. Producing glossy or silky effects on fabrics or other materials. Feb. 24.
[C.S.] 4211 (1905). Burdick. Colouring or decorating fabrics, paper, or other materials. Feb. 28.
,, 4644 (1905). Lemaire and Lemaire. Utilisation of waste fibres in the manufacture of linen thread. Feb. 28.
,, 7231 (1905). Riep and Bauer. Manufacture of a wool lubricant soluble in and readily washed out by water. Feb. 28.
,, 15,532 (1905). Venter. Apparatus for dyeing, mordanting, or bleaching loose materials, spun threads, cops, knitted goods and the like. Feb. 28.
,, 21,937 (1905). Lake (Leontieff). Dyeing vats. Feb. 28.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

[C.S.] 4211 (1905). Burdick. *See under* V.
,, 13,507 (1905). Wood. Wallpaper printing machines. Feb. 28.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 3536. Ponthus. Manufacture of a double acetate of copper and lime. [Fr. Appl., Aug. 31, 1905.]* Feb. 13.
,, 3583. Moscicki. *See under* XI.
,, 3680. Det Norske Aktieselskab f. Elektrokemisk Ind., and Halvorsen. Production of concentrated nitric and sulphuric acids from nitrosulphonic acid and nitrous sulphuric acid. [Appl. in Norway, Feb. 15, 1905.]* Feb. 14.

[A.] 3905. Applegarth and Quain. Production of ozone. Feb. 16.

„ 3994. Lance and Elworthy. Recovery of sulphurous acid and carbonic acid in the treatment of sulphurous ores or compounds or sulphates, and method of producing nitrogen. [Fr. Appl., Feb. 18, 1905.]* Feb. 17.

„ 4063. Krell. Tubes for concentrating acid.* Feb. 19.

„ 4199. Brunet. *See under* XIIIA.

„ 4219. Johnson (Badische Anilin und Soda Fabrik) Production of nitrites.* Feb. 20.

„ 4409. Lance and Elworthy. Synthetic production of ammonia, cyanogen, and nitrogen compounds generally. [Fr. Appl., Feb. 22, 1905.]* Feb. 22.

„ 4502. Clemm. Manufacture of alkali thiosulphate and alumina from alkali sulphate and bauxite or similar aluminiferous material. Feb. 23.

[C.S.] 2463 (1905). Piva. Process for treating leucite and substances containing the same. Feb. 21.

„ 26,435 (1905). Soc. l'Air Liquide. Liquefying atmospheric air in several portions differing in composition. Feb. 21.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 4399. Thame and Cornell. Process for treating china clay. Feb. 22.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

[A.] 3655. Jeroch, and Deutsche Ferrit-Cement Ges. Manufacture of cement. [Ger. Appl., Sept. 28, 1905.]* Feb. 14.

„ 3755. Jacobs. Production of a preservative for wood, metal and the like.* Feb. 15.

„ 3897. Zimmermann. Manufacture of artificial wood. Feb. 16.

„ 4486. Salomon. Production of weather-proof and non-inflammable timber.* Feb. 23.

„ 4503. Johnson (Koepp und Co.). Manufacture of stucco. Feb. 23.

[C.S.] 3617 (1905). Colloseus. Manufacture of cement from furnace slag. Feb. 28.

„ 14,329 (1905). Colloseus. *See under* X.

X.—METALLURGY.

[A.] 3528. Day. Process and apparatus for smelting ores and converting mattes.* Feb. 13.

„ 3575. Mills (Seigle). Extraction of gold, platinum, silver, nickel, copper and other metals. Feb. 13.

„ 3743. Woods and Schmidt. Recovery and separation of refuse metals and machinery therefor. Feb. 15.

„ 3901. Brinton. Process of treating manganese steel.* Feb. 16.

„ 3906. Steinhart and Vogel. Treatment of tin ores. Feb. 16.

„ 3978. Cook. Metallurgical processes. Feb. 17.

„ 4008. Isherwood. Extraction of zinc from zinc ores. Feb. 17.

[C.S.] 25,116 (1904) Moore. Apparatus for separating particles of gold and other metals from the gangue with which they are associated. Feb. 28.

„ 2532 (1905). Rumbold, Patchin and Hughes. Treatment of complex sulphide and oxidised ores for the recovery of zinc, nickel, cobalt, and manganese oxides, and of copper, arsenic, lead, bismuth, cadmium and tin. Feb. 21.

„ 2619 (1905). Gutensohn. Extraction of metals from ores and waste material. Feb. 21.

[C.S.] 3619 (1905). Colloseus. *See under* IX.

„ 6290 (1905). Wagner. Alloy. Feb. 21.

„ 13,141 (1905). Hoffmann. Manufacture of a substance for improving steel. Feb. 28.

„ 14,329 (1905.) Colloseus. Apparatus for pulverising blast furnace slag. Feb. 28.

„ 21,839 (1905). Saunders, and S. O. S. Synd., Ltd. Separation of metals from their ores. Feb. 28.

„ 23,592 (1905). Henning. Manufacture of foundry pig iron. Feb. 28.

„ 26,263 (1905). Frodingham Iron and Steel Co. Ltd., and Mannaberg. Blast furnaces. Feb. 28.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 3455. British Thomson-Houston Co., Ltd. (General Electric Co.). Magnetic material for electrical purposes. Feb. 12.

„ 3583. Moscicki. Apparatus for producing nitric oxides by electricity.* Feb. 13.

„ 3990. McCarty. Process for decomposing water by electrolysis. Feb. 17.

„ 4335. Bingham. Electric furnaces. Feb. 22.

„ 4336. Bingham. Electric furnaces. Feb. 22.

„ 4405. Weill. Apparatus for electroplating. Feb. 22.

„ 4519. Dolphin. Electrolytic deposition of copper. Feb. 24.

[C.S.] 778 (1905). Bloxam (Polzeniusz). Manufacture of accumulator plates. Feb. 28.

„ 5984 (1905). Price, Cox and Marshall. Electric furnaces and electrodes for use therein. Feb. 21.

„ 6790A (1905). Potthoff. Electroplating apparatus. Feb. 28.

„ 13,427 (1905). Kitsee. Secondary batteries. Feb. 21.

„ 13,689 (1905). Gardner (Thoresen and Tharaldsen). Deviating or drawing out electric arcs or discharges applicable to apparatus for the treatment of gases. Feb. 28.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 3521. Middleton, Iveson and Wilson. Cooling melted fats or fatty substances or the like. Feb. 13.

„ 4116. Wallbaum. Preparation of easily and durably emulsifiable fatty substances.* Feb. 19.

„ 4290. Harris. Process for purifying tallows. Feb. 21.

„ 4462. Innes-Baillie. Manufacture of soap. Feb. 23.

„ 4481. Lanza and Lanza. Process and apparatus for extracting olein and stearine from fatty acids. [Ital. Appl., Feb. 23, 1905.]* Feb. 23.

[C.S.] 3602 (1905). James (Roth). Apparatus for the rapid cooling of fluid soaps. Feb. 28.

„ 12,784 (1905). Perez y Garcia. Apparatus for heating oils and fats. Feb. 21.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(A.)—PIGMENTS, PAINTS.

[A.] 3446. Lance and de Joannis. Manufacture of paint material. [Fr. Appl., Feb. 16, 1905.]* Feb. 12.

„ 4199. Brunet. Obtaining lithopone from complex ores and other substances.* Feb. 20.

„ 4533. Leishman. Waterproofing composition applicable as a vehicle for pigments.* Feb. 24.

[C.S.] 12,998 (1905). Van der Schuijt, Kuntze and Overman. Process for preparing white paint. Feb. 21.

„ 16,787 (1905). Ruch. Manufacture of paints, varnishes and the like. Feb. 21.

(*B.*)—RESINS, VARNISHES.

[A.] 3563. Seeser. Manufacture of coverings for floors, walls, ceilings and the like.* Feb. 13.

„ 3788. Baringer. Process for rendering manilos copal, sandarach and like resinous substances insoluble in oil. [Ger. Appl., Feb. 25, 1905.]* Feb. 15.

[C.S.] 16,787 (1905). Ruch. *See under* XIIIA.

(*C.*)—INDIA-RUBBER.

[A.] 3416. Hood. Method and machine for purifying crude and reclaimed rubber and the like.* Feb. 12.

„ 3889. Grätz. Preparation of rubber for vulcanisation.* Feb. 16.

„ 4002. Penther. Process and apparatus for separating caoutchouc from fibrous materials.* Feb. 17.

„ 4307. Spencer and von Romocki. Treatment of india rubber. Feb. 21.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 3450. Arnold, Fox, Scott and Roberts. Manufacture of a colloidal material. Feb. 12.

„ 3516. Oakes. Process of treating hides. [U.S. Appl., March 31, 1905.]* Feb. 13.

„ 4122. Ohr and Schlegel. Method of protecting gelatin from the influence of moisture and heat.* Feb. 19.

„ 4561. Jensen. Composition for preserving leather.* Feb. 24.

„ 4570. Sadikoff. Manufacture of glue.* Feb. 24.

[C.S.] 21,443 (1905). Schowalter. Preparation for preserving and waterproofing leather. Feb. 21.

XV.—MANURES, ETC.

[A.] 3344. Harper. *See under* XVIIIB.

[C.S.] 10,023 (1905). Van Haeften. Apparatus for treating peat, particularly for making manures. Feb. 21.

XVI.—SUGAR, STARCH, GUM, ETC.

[C.S.] 5663 (1905). Hinze. Apparatus for lixiviating and washing sugar and other substances. Feb. 28.

XVII.—BREWING, WINES, SPIRITS, ETC.

[A.] 3786. Reul and Grund. Preparation of yeast. Feb. 15.

„ 3885. Reid, Le May, Christian and Adlam. Process of treating stout, beer, cider and other fermented liquids. Feb. 16.

„ 4274. Whitehouse and Beetlestone. Alcohol separation process. Feb. 21.

„ 4552. Hellwig. Preparing and filtering beer wash. Feb. 24.

[C.S.] 5845 (1905). Fränkel. Production of pure diastase. Feb. 21.

„ 13,834 (1905). Gothard. Treatment of yeast to render it suitable for commercial purposes. Feb. 28.

„ 21,754 (1905). Schrottky. Manufacture from grain of a material for use in brewing and for other purposes. Feb. 21.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(*A.*)—FOODS.

[A.] 3938. Loring. Fixation or addition of nitrogen to alimentary substances. Feb. 17.

„ 4365. Makin. Preparation of foods from yeast. Feb. 22.

„ 4403. Risberg. Manufacture of butter in centrifugal apparatus.* Feb. 22.

[C.S.] 4351 (1905). Hatmaker. Preservation of animal tissues. Feb. 21.

„ 12,112 (1905). Hudson. Manufacture of flour and apparatus therefor. Feb. 28.

„ 12,956 (1905). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of silk fibroin peptone. Feb. 21.

(*B.*)—SANITATION; WATER PURIFICATION.

[A.] 3444. Harper. Economic disposal of effluent from septic tanks for soil fertilisation.* Feb. 12.

„ 4537. Broadbent and Broadbent. Means for treating trade effluents. Feb. 24.

[C.S.] 7521 (1905). Brodie. Treatment of the clinker from refuse destructor furnaces. Feb. 21.

„ 12,797 (1905). Ramsden. Sludge separating tanks for sewage and like liquids. Feb. 28.

„ 24,435 (1903). Krüger. Water purifying apparatus. Feb. 21.

XIX.—PAPER, PASTEBOARD, ETC.

[A.] 4304. Dobler. Apparatus for impregnating paper and card in a paper making machine during its manufacture.* Feb. 21.

„ 4541. Sanguinetti. Oscillating cylindrical pulp strainers. Feb. 24.

„ 4577. Annison and Oliver. *See under* XXII.

[C.S.] 4211 (1905). Burdick. *See under* V.

„ 5766 (1905). Topham. Apparatus for filtering or pumping and regulating the flow of solutions of cellulose and the like. Feb. 28.

„ 10,880 (1905). Boult (Moritz and Moritz). Paper making apparatus. Feb. 21.

„ 14,385 (1905). Gagedois. Production of white pulps from natural vegetable matter or from coloured or dyed waste material for use in paper making. Feb. 21.

„ 1182 (1906). Soc. Franç. de la Viscose. Cellulose product and process of manufacturing same. Feb. 28.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 3367. Ewan and Young. Manufacture of guanidine salts. Feb. 12.

„ 4029. Seipermann and Fairweather. Manufacture of saccharin. Feb. 19.

„ 4050. Seipermann and Fairweather. Manufacture of saccharin and its salts. Feb. 19.

[C.S.] 2304 (1905). Oberländer, and Alliance Chemical Co. Manufacture of *o*-toluenesulphochloride. Feb. 21.

„ 11,058 (1905). Sommer. Production of anhydrides of organic acids. Feb. 21.

„ 12,843 (1905). Cooper (Bayer und Co.). Manufacture of new esters of aminoalcohols, and of salts thereof. Feb. 28.

„ 16,723 (1905). Ellis (Chem. Fabr. von Heyden, A.-G.). Manufacture of guaiacol sulphonic acids and of salts thereof. Feb. 21.

[A.] 3905. Applegarth and Quain. Production of ozone. Feb. 16.

„ 3994. Lance and Elworthy. Recovery of sulphurous acid and carbonic acid in the treatment of sulphurous ores or compounds or sulphates, and method of producing nitrogen. [Fr. Appl., Feb. 18, 1905.]* Feb. 17.

„ 4063. Krell. Tubes for concentrating acid.* Feb. 19.

„ 4199. Brunet. *See under* XIIIA.

„ 4219. Johnson (Badische Anilin und Soda Fabrik) Production of nitrites.* Feb. 20.

„ 4409. Lance and Elworthy. Synthetic production of ammonia, cyanogen, and nitrogen compounds generally. [Fr. Appl., Feb. 22, 1905.]* Feb. 22.

„ 4502. Clemm. Manufacture of alkali thiosulphate and alumina from alkali sulphate and bauxite or similar aluminiferous material. Feb. 23.

[C.S.] 2463 (1905). Piva. Process for treating leucite and substances containing the same. Feb. 21.

„ 26,435 (1905). Soc. l'Air Liquide. Liquefying atmospheric air in several portions differing in composition. Feb. 21.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 4399. Thame and Cornell. Process for treating china clay. Feb. 22.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

[A.] 3655. Jeroch, and Deutsche Ferrit-Cement Ges. Manufacture of cement. [Ger. Appl., Sept. 28, 1905.]* Feb. 14.

„ 3755. Jacobs. Production of a preservative for wood, metal and the like.* Feb. 15.

„ 3897. Zimmermann. Manufacture of artificial wood. Feb. 16.

„ 4486. Salomon. Production of weather-proof and non-inflammable timber.* Feb. 23.

„ 4503. Johnson (Koepp und Co.). Manufacture of stucco. Feb. 23.

[C.S.] 3617 (1905). Colloseus. Manufacture of cement from furnace slag. Feb. 28.

„ 14,329 (1905). Colloseus. *See under* X.

X.—METALLURGY.

[A.] 3528. Day. Process and apparatus for smelting ores and converting mattes.* Feb. 13.

„ 3575. Mills (Seigle). Extraction of gold, platinum, silver, nickel, copper and other metals. Feb. 13.

„ 3743. Woods and Schmidt. Recovery and separation of refuse metals and machinery therefor. Feb. 15.

„ 3901. Brinton. Process of treating manganese steel.* Feb. 16.

„ 3906. Steinhart and Vogel. Treatment of tin ores. Feb. 16.

„ 3978. Cook. Metallurgical processes. Feb. 17.

„ 4008. Isherwood. Extraction of zinc from zinc ores. Feb. 17.

[C.S.] 25,116 (1904) Moore. Apparatus for separating particles of gold and other metals from the gangue with which they are associated. Feb. 28.

„ 2532 (1905). Rumbold, Patchin and Hughes. Treatment of complex sulphide and oxidised ores for the recovery of zinc, nickel, cobalt, and manganese oxides, and of copper, arsenic, lead, bismuth, cadmium and tin. Feb. 21.

Official Notices.

EXTRAORDINARY GENERAL MEETING OF THE SOCIETY.

Notice is hereby given that an Extraordinary General Meeting of the Society will be held at 3.30 o'clock, precisely, in the afternoon of Tuesday, the twenty-seventh day of March, 1906, at the House of the Society of Arts, John Street, Adelphi, W.C., by kind permission of the Council of that Society, with the object of considering and adopting the resolution mentioned in the Requisition hereinafter set forth:—

"To the President and Council of the Society of Chemical Industry."

We, the undersigned Members of the Society of Chemical Industry, hereby request that, in accordance with Bye-Law 40, you will convene an Extraordinary General Meeting of the Society with the object of considering, and if approved by the said Extraordinary Meeting, of adopting the following resolution (that is to say):—

Resolution.

"That it is desirable that the Society of Chemical Industry as now existing should be incorporated under and subject to the grant of a Royal Charter and that the Council be and hereby is authorised to take all necessary steps to procure the grant of a Royal Charter of Incorporation."

Dated this twenty-second day of December, 1905.

Here follow signatures of the following:—

George Beilby.	Henry de Mosenthal.
V. G. Bloede.	Prof. Chas. E. Munroe.
Jas. H. Bowman.	Jas. P. Murray.
Eugene A. Byrnes.	Robert W. Neff.
Eustace Carey.	A. L. Norton.
Prof. Frank Clowes.	D. H. T Peploe.
Frederick P. Dewey.	Dr. W. H. Perkin.
Dr. Edward Divers.	Dr. Frederick B. Power.
Dr. A. R. L. Dohme.	Sir William Ramsay.
Thos. Fairley.	Sir Boverton Redwood.
Dr. Fred. W. Frerichs.	Walter F. Reid.
Oscar Guttmann.	President Ira Remsen.
Samuel Hall.	Sir Henry E. Roscoe.
Jas. Otis Handy.	George D. Rosengarten.
Dr. B. J. Harrington.	Dr. Samuel P. Sadtler.
Dr. Edward Hart.	Alfred Gordon Salamon.
Otto Hehner.	Dr. Karl F. Stahl.
E. Grant Hooper.	H. E. Stuart.
David Howard.	Sir Joseph W. Swan.
H. Aug. Hunicke.	H. P. Talbot.
C. C. Hutchinson.	M. J. Taylor.
Prof. Edward H. Keiser.	E. C. Thompson.
Prof. W. R. Lang.	Dr. T. E. Thorpe.
Ivan Levinstein.	Prof. W. A. Tilden.
Arthur R. Ling.	Thos. Tyrer.
Anthony McGill.	John H. Usmar.
Edward Mallinckrodt.	W. H. Van Winckel.
N. H. Martin.	S. S. Voorhees.
Prof. R. Meldola.	Dr. W. H. Walker.
Dr. Rudolph Messel.	R. A. Wallace.
Dr. W. Lash Miller.	Charles Wightman.
Dr. Ludwig Mond.	Dr. H. W. Wiley.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906.

The attention of Members is drawn to the Notice which accompanied the February 15th issue of the Journal.

The General Secretary will be obliged if those members, who have made arrangements directly with the Congress Committee in Rome, will forward their names to the Society, in order that arrangements may be made for a headquarters in Rome and for combined travelling. It would also be of service if they would indicate their contemplated date of departure and proposed route, and also whether they have a preference for any particular hotel in Rome.

Deaths.

Donald, Jas., 96, Anerley Park, Anerley, S.E.

Littlewood, Dr. Jas. B., Chief Examiner in Chemistry, Patent Office, Washington, D.C., U.S.A.

Lyte, F. Maxwell, 17, Mentone Mansions, Fulham Road, London, S.W. March 4.

Nottingham Section.

Meeting held at Derby on Wednesday, January 24th, 1906.

Mr. J. M. C. Paton in the Chair.

NOTES ON FOAMING GLUE.

By H. J. Watson.

The paper on this subject by Trotman and Hackford at the last meeting of this Section having given rise to some interesting discussion, it was thought that some notes, the results of some experiments, performed quite independently and without knowledge of their work, would prove an interesting adjunct to their paper.

The evils of foaming glues are well known to those connected with the trade, for, although a glue may in every other respect be excellent, it will be immediately condemned for many purposes if it foams. Among the various causes to which foaming in glue is attributed are the following:—(1) The presence of free alkali or alkaline earth; (2) Free acidity; (3) The addition of zinc compounds; (4) Prolonged heating either in open pans or under pressure; (5) the presence of mucin pointed out by Rideal. It was with the object of throwing further light on the cause of foaming that a series of experiments were commenced. A difficulty experienced at the outset was the absence of a reliable comparative test, by which the amount of foam produced by a glue could be measured with any degree of accuracy.

The following is the method usually described in text books:—"A 10 to 20 per cent. solution of glue is stirred with an egg-beater or glass rod for a few seconds; the height of the foam is measured in inches." No test could be more vaguely described, and more useless. This being so, the method communicated to the discussion on Trotman and Hackford's paper was devised (see this J., Feb. 15, pages 108—9), and has been used in the experiments described in these notes.

(1) *The effect of free alkali.*—For this experiment a sample of British-made bone glue was used. When broken up, two quantities of 5 grms. each were weighed out; to one 5 c.c. and to the other 10 c.c. of N/5 sodium hydroxide solution were added, and both were then subjected to the foam test with the following result:—

Table I.

Weight of glue taken in grms.	c.c. of N/5 sodium hydroxide added.	Made up to c.c.	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
5	—	50	73	45	28
5	5	50	78	45	33
5	10	50	80	45	35

It does not appear from the result of this experiment that the presence of free alkali materially increases the amount of foam, the amount present being considerably more than would be found in an ordinary sample of glue, but it is believed that it would tend to produce foam in two ways if present in the material from which the glue was made, or if added in the course of extraction. First, it would combine with any grease to form a soap, and,

secondly, it would assist in the formation of gelatone, the effect of which is dealt with later on.

(2) *The effect of free acidity.*—Using the same sample of glue to test the effect of free acid in glue, the results, which will be given in Table II., were obtained :—

TABLE II.

Weight of glue taken in grms.	Substance added.	Made up to c.c.	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
5	5 c.c. N/5 H_2SO_4	50	75	45	30
5	10 c.c. N/5 H_2SO_4	50	90	45	45
5	5 c.c. H_2SO_3 ·75% SO_2.	50	86	45	41

As in the case of free alkali, the acidity is higher than would be expected in an ordinary sample of glue, so that free acidity can hardly be considered as tending to produce foaming in glue. It has been found, however, as will be seen from the following experiments, that sulphurous acid, sometimes used as a preservative and bleaching agent, does, as one would expect, tend to increase the foam, though not considerably. Four sample cakes of glue were obtained as follows :—(1) Bleached with sulphurous acid (boric acid present); (2) Unbleached (boric acid present); (3) Bleached (boric acid absent); (4) Without bleaching or boric acid. 5 grms. of each subjected to the foam test gave the following results :—

TABLE III.

No.	Weight of glue taken in grms.	Made up to c.c	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
1	5	50	82	45	37
2	5	50	77	45	32
3	5	50	80	45	35
4	5	50	76	45	31

Boric acid appears to have little or no influence on the amount of foam produced.

(3) *The effect of zinc compounds.*—Zinc sulphate appears to lengthen the time required for the foam to die away.

(4) *The effect of heat.*—500 c.c. of a 10 per cent. solution of glue, 50 c.c. of which gave 28 c.c. of foam, was kept at a temperature of 180° F. for seven hours. At the end of the first hour 50 c.c. taken out gave 30 c.c. of foam; after three hours 33 c.c. of foam, and after seven hours 37 c.c. of foam. A gradual increase in the amount of foam is produced as the period under heat is lengthened. 500 c.c. of a 10 per cent. solution of glue having a foam test of 22 c.c. was made. This was also kept at a temperature of 180° F. for seven hours with similar results. After the first hour there were 24 c.c. of foam, after the second 27 c.c. of foam, at the end of seven hours 32 c.c. of foam.

From these results it appears that heat must be a very important factor in producing foam, and further experiments confirm this.

A sample of glue-size was taken at a stage in the process of manufacture where the period under heat had only been short. A portion was made into a 10 per cent. solution, no preservative being present. 50 c.c. of this solution subjected to the foam test gave only 20 c.c. of foam which rapidly died away. After further treatment with boric acid and bleaching 50 c.c. of a 10 per cent. solution gave 25 c.c. of foam. The glue-size then underwent a further period of heating for concentration, and, when a sample was diluted to a 10 per cent. solution, it registered as much as 45 c.c. of foam. Other sample cakes of glue made from glue-size, taken at the early stage of the process of manufacture as in the last experiment, were then tested in the usual way; 5 grms., made up to 50 c.c., gave 20 c.c. of foam which soon disappeared. Sample cakes obtained from the final stage of the process tested in the same way, gave 42 c.c. of foam.

Heat, then, appears to be the all-important factor in producing foaming glue; the prolongation of the time under heat in the process of manufacture only tends to produce foaming glue, and the manufacturer who succeeds in reducing the period under heat to the shortest possible will, in all probability, produce the least foaming glue. It would be a rather difficult problem to manufacture glue without heat, but I am convinced that by careful attention and improved methods of manufacture the amount of foam in glue could be reduced to a minimum.

The next question to consider was, in what way does heat tend to bring about foaming? The only theory which seems to suggest itself as a probable explanation is that, under the continued influence of heat, hydrolysis of the gelatin (first formed from the collagen of the material operated upon) to gelatone must take place. Trotman and Hackford have shown that, under the influence of heat, the nitrogen precipitated by zinc sulphate decreases, and what they term peptone, or gelatone, nitrogen increases; and it has been shown in this paper that the foam also increases, so that it would appear reasonable to conclude that gelatone is the principal foam-producing substance in glue.

Gelatone not being obtainable, the analogous substance, peptone, was used in some experiments.

Five grms. of dry peptone, treated like a sample of glue in the foam test, gave so much foam that it was impossible to measure it.

Experiments were then made by adding to glue varying quantities of dry peptone and estimating the amount of foam produced with the following results :—

TABLE IV.

The effect of peptone.

Weight of glue taken in grms	Peptone added in grms.	Made up to c.c.	c.c. to top of foam.	c.c to top of solution.	c.c. foam.
5	0·02	50	78	45	33
5	0·05	50	85	45	40
5	0·10	50	93	45	48
5	0·50	50	above 100	45	above 55

Peptone and gelatone being analagous substances it appears reasonable that gelatone would act in a similar manner to peptone in producing foam.

(5) *The presence of Mucins.*—If gelatones were the only foam-producing substance in gelatin or glue, one would expect to find a proportional relation between the gelatone nitrogen of glue and the amount of foam produced; generally speaking, this is so, but exceptions have been found, as will be seen on reference to the following table :—

TABLE V.

No.	Total nitrogen as gelatin.	Gelatin by $ZnSO_4$	Gelatone N by difference as gelatin.	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
1	78·26	58·53	19·73	95	45	50
2	79·56	72·19	7·37	73	45	28
3	78·26	72·19	6·87	78	45	25
4	74·36	61·89	12·47	83	45	38

Nos. 1 and 4 were known to be prepared from material which underwent little or no preparation prior to boiling, while Nos. 2 and 3, though going through the same boiling process, were made from prepared material—No. 3 receiving rather better cleansing than No. 2. The presence of mucins would explain this difference, and confirmation has been obtained on this point by adding to solutions of glue, varying quantities of wash waters from the cleansing operations, and estimating the foam produced; with increasing quantities of wash water there was a corresponding increase in the amount of foam.

Grease as a foam-producing factor has not been experimented with, because, with the improved methods of degreasing material, it is very rarely that one comes across grease in glue in these days.

Conclusions.—By the selection of good material and

subjecting it to thorough degreasing and cleansing operations, and then reducing the period under heat to the shortest possible, it is thought that a glue would be obtained that would be practically foam free; but even if the material be well prepared and the boiling operations neglected one must be prepared to find foaming glue resulting.

Over a large range of samples from various sources, British and foreign, no sample of glue has been found to be foam free by my test.

Journal and Patent Literature.

I.—PLANT, APPARATUS & MACHINERY.

(*Continued from page* 168.)

English Patent.

Separators for liquids; Centrifugal ——. Aktiebolaget Separator and E. A. Forsberg, Stockholm. Eng. Pat. 21,190, Oct. 18, 1905.

The claim is for a separator in which the relative proportions of the separated liquids can be regulated by resistances which are adjustable from the outside of the bowl. The resistances consist of strips, wings, &c., placed between the inner wall of the bowl and the liner, between the bowl and the upper plate, or in the space between the bowl and the top disc.—W. H. C.

United States Patents.

Drying-machine. J. H. Lorimer, Philadelphia, Pa. U.S. Pat. 811,306, Jan. 30, 1906.

The material to be dried is carried between a pair of endless bands or aprons of open-work through a chamber through which air circulates. The bands have sprocket chains at their edges which pass over guide-wheels at either end of the chamber, where they are slightly separated to allow of the supply or discharge of the material being treated. The bands travel backwards and forwards within the chamber, and the upper band is prevented by guides fixed to the walls of the chamber from pressing too heavily upon the lower one which carries the material. —W. H. C.

Drying and Conditioning machine. J. H. Lorimer, Philadelphia, Pa. U.S. Pat. 811,307, Jan. 30, 1906.

A drying and a conditioning chamber are placed end to end and the materials to be treated are passed through them in succession, being carried on an endless band in a manner similar to that described in the preceding abstract. The drying and the conditioning mediums are circulated in each chamber independently.—W. H. C.

Furnace. T. Suzuki, Sunamura, Japan. U.S. Pat. 812,380, Feb. 13, 1906.

See Eng. Pat. 3015 of 1905; this J., 1905, 1054.—T. F. B.

Furnaces; Method of preserving the inner walls of ——. F. C. W. Timm, Hamburg. U.S. Pat. 812,619, Feb. 13, 1906.

See Fr. Pat. 353,566 of 1905; this J., 1905, 1020.—T. F. B.

French Patent.

Gaseous mixtures, especially the oxygen and nitrogen of the air; Apparatus for mechanically separating ——. E. F. M. Farcot. Fr. Pat. 358,397, Oct. 10, 1905.

The gaseous mixture is led into a box or chamber made in the form of a sector of a circle, the inlet being at the centre of the circle. This box is rapidly rotated, whereby, it is claimed, the lighter gas is carried round with it, whilst the heavier gas tends to collect in that portion rearmost to the direction of rotation.—A. S.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 170.)

Power production; Modern —— and its relation to the coal resources of Great Britain. G. T. Beilby. Address to the Glasgow University Eng. Soc., Jan. 11, 1906.

At a moderate estimate there are in Great Britain steam engines and boilers with a yearly output of 5,000,000 h.p. which consume not less than 5 lb. of coal per i.h.p. hour or, roughly, 50,000,000 tons per annum (see this J., 1899, 643). The author advocates the use of gas engines and steam turbines whereby the coal consumption might be reduced to 1·5 lb. per i.h.p. hour, or a total of 12,000,000 tons. This would imply an annual saving of £9,800,000, whilst the cost of making the change in plant need not exceed £50,000,000, or, if the power is to be delivered as electricity, £60,000,000. The use of producer gas, such as Mond gas, in efficient internal combustion engines or the employment of steam turbines, gives a means of producing power in bulk as cheaply as at certain of the more important water-power stations in America and Europe. Apart from the gains to the individual manufacturer who consumes, and the engineer who supplies this power, the nation derives a great economic advantage by the conservation of its coal resources, more especially in view of the steadily increasing demand for power per head of the population, which, if it had to be met by the old wasteful system, would still further tax the coal resources. —R. L.

Bunsen flame; Study of the ——. W. Allner. J. Gasbeleucht., 1905, **48**, 1035-1041, 1057—1066, 1081—1086, 1107—1112.

Haber and Richardt (this J., 1904, 976) have shown that the temperature of the inner cone of a Bunsen flame (see this J., 1891, 992, 993) supplied with coal gas, may be calculated from the chemical composition of the products of combustion, by making use of the alteration of the constant k of the equilibrium $\frac{H_2O.CO}{CO_2.H_2}$ with the temperature. The author has extended this investigation to the cases of flames supplied with mixtures of: carbon dioxide and hydrogen, carbon monoxide and hydrogen, methane and hydrogen, methane, hydrogen and carbon dioxide, benzene and hydrogen, benzene, hydrogen and carbon dioxide, and pure benzene. In all these cases, except with the two first-mentioned mixtures, the temperature could be calculated from the composition of the products of combustion, but in the case of the benzene flame, it was found necessary to withdraw the combustion gases from the lower portion of the flame, since with such a hot flame (about 2000° C.) the equilibrium is displaced during the withdrawal of the gases through the cooling zone at the upper part of the inner flame. In the case of the mixtures of hydrogen with carbon dioxide and carbon monoxide respectively, it is probable that the temperatures produced are not sufficiently high for equilibrium to be attained in a short time.—A. S.

Auer burner; Radiation of the ——. H. Rubens. J. Gasbeleucht., 1906, **49**, 25—30.

The author examined the total emission spectra of the incandescent Auer mantle, the spectral region studied ranging from $\lambda = 0{\cdot}45\mu$ to $\lambda = 18\mu$. Measurements were made with an incandescent Auer mantle, the Bunsen flame,

secondly, it would assist in the formation of gelatone, the effect of which is dealt with later on.

(2) *The effect of free acidity.*—Using the same sample of glue to test the effect of free acid in glue, the results, which will be given in Table II., were obtained :—

TABLE II.

Weight of glue taken in grms.	Substance added.	Made up to c.c.	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
5	5 c.c. N/5 H_2SO_4	50	75	45	30
5	10 c.c. N/5 H_2SO_4	50	90	45	45
5	5 c.c. H_2SO_3 ·75% SO_2.	50	86	45	41

As in the case of free alkali, the acidity is higher than would be expected in an ordinary sample of glue, so that free acidity can hardly be considered as tending to produce foaming in glue. It has been found, however, as will be seen from the following experiments, that sulphurous acid, sometimes used as a preservative and bleaching agent, does, as one would expect, tend to increase the foam, though not considerably. Four sample cakes of glue were obtained as follows :—(1) Bleached with sulphurous acid (boric acid present); (2) Unbleached (boric acid present); (3) Bleached (boric acid absent); (4) Without bleaching or boric acid. 5 grms. of each subjected to the foam test gave the following results :—

TABLE III.

No.	Weight of glue taken in grms.	Made up to c.c	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
1	5	50	82	45	37
2	5	50	77	45	32
3	5	50	80	45	35
4	5	50	76	45	31

Boric acid appears to have little or no influence on the amount of foam produced.

(3) *The effect of zinc compounds.*—Zinc sulphate appears to lengthen the time required for the foam to die away.

(4) *The effect of heat.*—500 c.c. of a 10 per cent. solution of glue, 50 c.c. of which gave 28 c.c. of foam, was kept at a temperature of 180° F. for seven hours. At the end of the first hour 50 c.c. taken out gave 30 c.c. of foam; after three hours 33 c.c. of foam, and after seven hours 37 c.c. of foam. A gradual increase in the amount of foam is produced as the period under heat is lengthened. 500 c.c. of a 10 per cent. solution of glue having a foam test of 22 c.c. was made. This was also kept at a temperature of 180° F. for seven hours with similar results. After the first hour there were 24 c.c. of foam, after the second 27 c.c. of foam, at the end of seven hours 32 c.c. of foam.

From these results it appears that heat must be a very important factor in producing foam, and further experiments confirm this.

A sample of glue-size was taken at a stage in the process of manufacture where the period under heat had only been short. A portion was made into a 10 per cent. solution, no preservative being present. 50 c.c. of this solution subjected to the foam test gave only 20 c.c. of foam which rapidly died away. After further treatment with boric acid and bleaching 50 c.c. of a 10 per cent. solution gave 25 c.c. of foam. The glue-size then underwent a further period of heating for concentration, and, when a sample was diluted to a 10 per cent. solution, it registered as much as 45 c.c. of foam. Other sample cakes of glue made from glue-size, taken at the early stage of the process of manufacture as in the last experiment, were then tested in the usual way; 5 grms., made up to 50 c.c., gave 20 c.c. of foam which soon disappeared. Sample cakes obtained from the final stage of the process tested in the same way, gave 42 c.c. of foam.

Heat, then, appears to be the all-important factor in producing foaming glue; the prolongation of the time under heat in the process of manufacture only tends to produce foaming glue, and the manufacturer who succeeds in reducing the period under heat to the shortest possible will, in all probability, produce the least foaming glue. It would be a rather difficult problem to manufacture glue without heat, but I am convinced that by careful attention and improved methods of manufacture the amount of foam in glue could be reduced to a minimum.

The next question to consider was, in what way does heat tend to bring about foaming? The only theory which seems to suggest itself as a probable explanation is that, under the continued influence of heat, hydrolysis of the gelatin (first formed from the collagen of the material operated upon) to gelatone must take place. Trotman and Hackford have shown that, under the influence of heat, the nitrogen precipitated by zinc sulphate decreases, and what they term peptone, or gelatone, nitrogen increases; and it has been shown in this paper that the foam also increases, so that it would appear reasonable to conclude that gelatone is the principal foam-producing substance in glue.

Gelatone not being obtainable, the analogous substance, peptone, was used in some experiments.

Five grms. of dry peptone, treated like a sample of glue in the foam test, gave so much foam that it was impossible to measure it.

Experiments were then made by adding to glue varying quantities of dry peptone and estimating the amount of foam produced with the following results :—

TABLE IV.

The effect of peptone.

Weight of glue taken in grms	Peptone added in grms.	Made up to c.c.	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
5	0·02	50	78	45	33
5	0·05	50	85	45	40
5	0·10	50	93	45	48
5	0·50	50	above 100	45	above 55

Peptone and gelatone being analagous substances it appears reasonable that gelatone would act in a similar manner to peptone in producing foam.

(5) *The presence of Mucins.*—If gelatones were the only foam-producing substance in gelatin or glue, one would expect to find a proportional relation between the gelatone nitrogen of glue and the amount of foam produced; generally speaking, this is so, but exceptions have been found, as will be seen on reference to the following table :—

TABLE V.

No.	Total nitrogen as gelatin.	Gelatin by $ZnSO_4$	Gelatone N by difference as gelatin.	c.c. to top of foam.	c.c. to top of solution.	c.c. foam.
1	78·26	58·53	19·73	95	45	50
2	79·56	72·19	7·37	73	45	28
3	78·26	72·19	6·87	78	45	25
4	74·36	61·89	12·47	83	45	38

Nos. 1 and 4 were known to be prepared from material which underwent little or no preparation prior to boiling, while Nos. 2 and 3, though going through the same boiling process, were made from prepared material—No. 3 receiving rather better cleansing than No. 2. The presence of mucins would explain this difference, and confirmation has been obtained on this point by adding to solutions of glue, varying quantities of wash waters from the cleansing operations, and estimating the foam produced; with increasing quantities of wash water there was a corresponding increase in the amount of foam.

Grease as a foam-producing factor has not been experimented with, because, with the improved methods of degreasing material, it is very rarely that one comes across grease in glue in these days.

Conclusions.—By the selection of good material and

vided with a similar valve, 17, and 16. If it be desired that the gas should be permeated by the liquid in the form of a spray, spraying nozzles, 24, may be provided. —R. L.

Gases; Portable storage vessels for liquified ——. P. Heylandt, Erfurt, Germany. Eng. Pat. 17,884, Sept. 4, 1905.

Two concentric vessels which are connected together only at the neck are used, the liquefied gas being contained in the inner one and as perfect a vacuum as possible being maintained in the space between them. The inner vessel is made of porcelain or of some similar non-conducting material which is "air-tight, solid, and highly unsusceptible of very considerable change of temperature," while the outer vessel may be of the same or a similar material or of metal. The vessel is suspended, within an outer protecting case, by an elastic frame carried on trunnions by another frame similarly attached to the outer case, the whole suspending arrangement being similar to that used for suspending the mariners' compass, and known as a gimbal. The inner double vessel is consequently maintained in an upright position when the outer case is inclined. The neck of the inner vessel is bent outwardly and downwardly, in order to remove the joint between the two concentric vessels as far as possible from the influence of the cold, and it is covered by a metal cap with a central tubular opening closed by a plug of porous material. —W. H. C.

Mantles for gas burners; Incandescent — —. J. E. T. Woods, West Norwood. Eng. Pat. 8162, April 17, 1905.

A THIN wire, composed of an alloy of nickel, cobalt, tungsten, tin and copper, is covered with asbestos; the covered filament is woven into mantles, impregnated with glucinum chloride and a cerium salt, and baked a tover 600° F. to convert the salts into oxides.—H. B.

Tantalum wire; Incandescence bodies of — — *for electrical glow lamps.* Siemens und Halske Akt. Ges., Berlin. Eng. Pat. 18,403, Sept. 12, 1905. Under Int. Conv., Oct. 13, 1904.

SEE Addition to Fr. Pat. 321,412 of 1902; following these.—T. F. B.

UNITED STATES PATENTS.

Gas producers. C. Ellis. Assignor to Combustion Utilities Co., New York. U.S. Pat. 811,208, Jan. 30, 1906.

THE producer is constructed of a shell with a closed lower end forming the ash chamber; a partition across the chamber divides it into compartments, each containing a screw conveyor for removing the ash; an upwardly tapering baffle-wall extends across the shell above the partition and at an angle thereto; and blast tuyères, projecting through the sides of the shell, are directed against the baffle-wall.—H. B.

Gas; Apparatus for generating ——. B. E. Eldred and C. Ellis. Assignors to Combustion Utilities Co. New York. U.S. Pat. 811,706, Feb. 6, 1906.

THE claim is for the combination of a gas-producer with a water-gas generator. A regulated proportion of carbon dioxide from the flues of a steam boiler is mixed with the air supplied to the producer, and the products from the two generators can be mixed in any desired proportions by regulating valves fixed on the mains leading from the generators to the distributing main.—W. H. C.

FRENCH PATENTS.

Mantles [jute fabrics]; Incandescence ——. T. Schiefner. Fr. Pat. 358,252, Oct. 4, 1905.

JUTE is employed for the manufacture of mantle fabrics in the usual way.—H. B.

Incandescence electric lamps; Manufacture of ——. Siemens und Halske A.-G. First Addition, dated Sept. 14, 1905, to Fr. Pat. 321,412, May 26, 1902 (this J., 1903, 206).

IN order to harden a filament composed of tantalum, the metal is fused beforehand with the addition of a minute proportion of oxygen, hydrogen, carbon, silicon, aluminium, tin or titanium. For example, an addition of about 0·05 per cent. of carbon hardens the product considerably.—H. B.

Incandescence electric lamps; Manufacture of metallic conducting bodies [tungsten and molybdenum] for ——. A. Just, F. Hanaman, Ver. Elektrizitäts A.-G., H. Landesberger and I. Salzmann. Fr. Pat. 358,272, Oct. 4, 1905.

IN manufacturing filaments of tungsten or molybdenum, if the fused metal, which always contains some carbide, be used as starting material, it is first drawn into wires and these are then heated *in vacuo* by means of a progressively increasing current, so as to distil off the carbon and thus raise the fusing point of the filament. If the starting material be a reducible compound, such as the oxide or sulphide, it is made into a plastic mass by means of water or other volatile non-carbonaceous agglutinant, moulded into the desired form, and heated intensely in an atmosphere of hydrogen. If the pulverulent metal be used, it is first rendered plastic by mixing it with sulphur and a sufficiency of carbon bisulphide, or by heating it with sulphur till the latter becomes plastic; the plastic mass is moulded to the desired form, and heated in hydrogen, so that the sulphide first formed is reduced to the metallic state.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 172.)

Coal; Decomposition of —— *at relatively low temperatures.* E. Boernstein. Verh. d. Ges. Deutsch. Ntf. u. Aerzte, 1904, II. Theil., I. Hälfte, 141—142. Chem. Centr., 1906, 1, 497.

EXPERIMENTS were carried out with eight different Westphalian coals; from 3 to 5 kilos. of each were subjected to a kind of fractional distillation, the temperature being kept constant at certain points until the decomposition at such temperature was complete; the highest temperature attained in the experiments was 450° C. The distillation residues, although showing essential differences, were more nearly alike in composition than the original coals. The amounts of the aqueous distillates from the coals were in the same order as the "oxygen-numbers" of the raw materials; they contained small quantities of ammonia and hydrogen sulphide, and also catechol (except in the case of Shamrock bituminous coal—"Fettkohle"); phenol, on the other hand, was only present in one case, and then only in traces. The gaseous products of distillation did not exhibit differences corresponding with those shown by the different coals; compared with ordinary coal-gas, they were characterised by a higher content of heavy hydrocarbons (5—14 per cent.) and of methane and its homologues (55—76 per cent.), and a lower content of hydrogen (5—16 per cent.). Of the tars, seven had a specific gravity between 0·95 and 0·98, whilst the eighth had the sp. gr., 1·03. Their "hydrogen- and oxygen-numbers" corresponded roughly with those of the coals from which they were derived, and there was some relation between the "oxygen-numbers" and the content of higher phenols. The tars from the bituminous, gas, and flaming coals began to distil at about 70°—80° C., but the tar from a forge-coal only at 115° C.; they did not contain any aniline, thiophene, naphthalene or anthracene. The seven light tars contained quantities of paraffins (m. pt. 55°—60° C.) ranging from 0·3 to 2 per cent.; the eighth higher-boiling tar was free from paraffin, but from the fraction distilling at 375°—435° C. obtained from it, a small quantity of greenish-yellow crystals, probably isomethylanthracene was separated.—A. S.

Petroleum; Boryslaw crude ——. M. Wielezynski. Chem.-Zeit., 1906, **30**, 106—109.

THE analysis of 21 samples gave the following range of values:—Sp. gr. at 17·5° C., 0·8368—0·9634; yield of crude "benzine" (sp. gr. 0·750), 5·2—19 per cent.; petroleum distillate (sp. gr. 0·750—0·850), 37—51 per cent.; paraffin, 0·58—13·8 per cent. (though only three samples gave less than 6·5 per cent.). These figures, however, do not represent the commercial oil, which is warmed to facilitate the separation of dirt and water, and often also before piping, so that a considerable quantity of the light constituents is dissipated. The author concludes that though there are no great fluctuations in the composition of Boryslaw oil, which is, in the main, poor in light fractions ("benzine") and rich in paraffin, it cannot be regarded as homogeneous. Changes are even noticeable in the oil from one and the same well when the latter has been worked for some considerable time. Wells at lower levels produce oil richer in paraffin than those at higher levels, though in the latter the oil appears in association with ozokerite.—C. S.

Pseudocumene in Roumanian petroleum; Presence of ——. P. Poni. Ann. Scient. de l'Univ. de Jassy, **3**, 217—218. Chem. Centr., 1906, **1**, 459.

THE author has succeeded in identifying pseudocumene in Roumanian petroleum. It has previously been detected in the petroleums from Rangoon, Baku, Pennsylvania, Ohio, Caucasus, Pechelbronn (Alsace), Tarnow (Galicia), and Terro de Lavoro (Italy).—A. S.

Petroleum; Bleaching the distillation residues of ——. K. Charitschkow. Westnik shirow. weschtsch., 1905, **6**, 135. Chem.-Zeit., 1906, **30**, Rep., 35.

RECENTLY, in the manufacture of lubricating oils, the purification of the products has been effected, not by distillation, but by means of chemical reagents; these products, which constitute the so-called "viscosine," have a high viscosity. The residues are freed from resinous substances, and bleached to a certain extent by treatment with sulphuric acid; the residues from Grosny petroleum are more easily bleached in this way than the residues of Baku petroleum. The residue from Baku lubricating oil ("goudron") is very difficult to bleach; even when dissolved in benzine and treated with sulphuric acid, it remains black and opaque. For those products which are not readily acted upon by sulphuric acid alone, an addition of 4 per cent. of potassium bichromate on the weight of the acid, is advantageous. By treatment with this reagent a solution of "goudron" in benzine or ligroin, becomes dark brown in colour, and clear. The action of the sulphuric acid and potassium bichromate reagent on 10 samples of Baku "goudron" was examined. After the treatment, the oil was washed with caustic soda. The sum of the percentages of treated oil and resinous matter removed was invariably greater than 100. In many cases the specific gravity of the solution of the "goudron" in benzine was higher after the acid treatment than before.—A. S.

Petroleum Production of the United States. Oil, Paint and Drug Reporter. Through Chem. Trade J., Feb. 24, 1906.

THE production of petroleum in the United States during the year 1905 has shown considerable increase over that of the year preceding, due to the active prosecution of the search for oil in the newer producing sections, notably in the State of Kansas, in Oklahoma and Indian Territories, and in California, while the older producing States, Pennsylvania, West Virginia, New York, Ohio, and Indiana, show a marked decrease. In Texas and Louisiana the increase has been considerable, while in California the increase has been steady. It may well be doubted if Texas can maintain the present rate of production, as there has been a steady decrease during the past few months. The total production in the United States during 1905 was fully 137,000,000 barrels, of which California is credited with 35,000,000 barrels, Texas 30,000,000 barrels, Louisiana 10,000,000 barrels, Kansas and the Territories 12,000,000 barrels, the Pennsylvania fields (including West Virginia, New York, and South-East Ohio) 28,000,000 barrels, and the Ohio and Indiana fields, producing what is known as the Lima grades of oil, 19,000,000 barrels.

The export movement in the various petroleum products, while showing an increase of 179,710,000 galls., did not meet the expectations that had been entertained. It was the general belief that owing to the war in the Far East, and later to the almost total destruction of the Russian oil producing and refining plants, the demand for American oil would be increased to an extent which would tax the capacity of the refineries. It appeared, however, that the producers in Roumania, Galicia, Sumatra and Borneo entered the field, and competition followed to secure the trade the Russians had enjoyed, the result being that only a part of this trade fell to the American refiners. All the products, however, showed an increase in the amounts exported. The exports of crude oil during the past year showed an increase of 6,290,000 galls., the increase being entirely in the shipments of Texas fuel oil. The export movement has been very irregular, the amounts being, in gallons:—1903, 121,984,693; 1904, 95,974,645; 1905, 102,264,117.

The exports of illuminating oil showed an increase of 113,097,000 galls., an increase which was considerably smaller than had been expected as a result of the conditions affecting the markets abroad. The shipments increased largely following the destruction of the Russian refineries, but during the last three months showed a considerable decrease. American oil, however, generally receives preference in the European markets by reason of its superior quality, but as the oil from other countries is sold at a lower price, these have shared largely in the increased requirements. The exports were:—1903, 672,298,439 galls.; 1904, 745,742,071 galls.; 1905, 858,839,713 galls. [T.R.]

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 176.)

Diphenylmethane series; Studies of reduction in the ——. H. Duval. Comptes rend., 1906, **142**, 341—342.

THE author has studied the action of reducing agents upon azodiaminodiphenylmethane. Stannous chloride in acid solution reduces this body and converts it into a tetramine of the benzidine type with rupture of the -N : N- linkage. The product, tetraminodiphenylmethane, $(NH_2)_2C_6H_3.CH_2.C_6H_3(NH_2)_2$, forms a tetrabenzoyl derivative, m. pt. 275° C. The reduction by zinc dust in alkaline media follows another course. The azo-group is reduced to the hydrazo state, and when the reduced solution is heated with hydrochloric acid, ammonium chloride is split off and *p*-diamino-acridine, m. pt. 284° C. is obtained. —J. F. B.

Diazonium salts; Replacement of negative radicals by hydroxyl radicals in ——. E. Noelting and M. Battegay. Ber., 1906, **39**, 79—86.

IN certain diazonium compounds containing electronegative radicals, halogen, nitro, or sulphonic groups can be replaced by hydroxyl groups at the ordinary temperature under the influence of sodium bicarbonate or acetate, or sometimes even in acid solution. The behaviour of the diazo compounds from 2.5.6-trichloroaniline-3-sulphonic acid, *o*-nitroaniline-*p*-sulphonic acid, 2.5-dichloroaniline-4-sulphonic acid and 2-chloroaniline-4-sulphonic acid in this direction was investigated by the authors. 2.5.6-Trichloroaniline-3-sulphonic acid was prepared by nitrating and reducing 1.2.4-trichlorobenzene-

5-sulphonic acid, according to the method described in Ger. Pat. 139,327. It forms white needles, readily soluble in hot water, but only slightly in cold water. Its sodium salt is readily soluble, the barium salt soluble with difficulty. On diazotisation at 20°—25° C. in the usual manner this acid forms the corresponding diazoniumsulphonic anhydride, $C_6HCl_3<^{N_2}_{SO_2}$, which yields azo dyestuffs not differing much in shade from those from *m*-aminobenzenesulphonic acid. The dyestuff formed with β-naphthol dyes wool in fine orange shades. With a hydrochloric acid solution of cuprous chloride the diazo compound readily forms 2.3.4.5-tetrachlorobenzene-sulphonic acid, which is readily soluble in water. If the trichlorodiazoniumsulphonic anhydride is introduced into a cold aqueous solution of 2 mols. of sodium bicarbonate or acetate the solution turns yellow and the dichlorodiazophenolsulphonic acid is formed. This is converted by a hydrochloric acid solution of cuprous chloride into trichlorophenolsulphonic acid and combines with β-naphthol to form the corresponding azo dyestuff, which yields on reduction 3.6-dichloro-2-aminophenol-4-sulphonic acid. The azo dyestuff dyes wool in red shades with a brownish tint, which are turned to violet-brown by the action of alkalis, and to violet, fast to alkalis, by treatment with bichromate and sulphuric acid. If the dyeings on wool are treated with copper sulphate fine crimson shades are obtained. 2.4.6-Tribromoaniline-4-sulphonic acid was obtained according to the method of Berndsen (Annalen, **177**, 86), by the action of excess of bromine on metanilic acid. It is diazotised in the same manner as the trichloro-acid. The dyestuff formed with β-naphthol yields very similar shades to those from the trichloro compound and from metanilic acid. The dyeings are not sensitive to alkalis. By the action of sodium bicarbonate on the diazo compound, 1 mol. of bromine is replaced by hydroxyl. The product was not isolated, but was combined with β-naphthol. By analogy with the chloro-derivative it is probable that the bromine atom in position 6 is replaced, 2.4-dibromo-6-hydroxydiazobenzene-3-sulphonic acid being formed. The β-naphthol dyestuff yields red shades on wool, unstable to alkalis, which are converted into dark violet shades, fast to alkalis, by chroming. 2.5-Dichloroaniline-4-sulphonic acid was prepared by Noelting and Kopp (Ber., 1905, **38**, 3513). Its diazo-anhydride is prepared in the usual manner and combines with β-naphthol to form a dyestuff yielding very similar shades to Orange II., the corresponding derivative of sulphanilic acid. If the diazo-anhydride is treated with sodium bicarbonate and then combined with β-naphthol a red dyestuff is obtained, showing the typical reactions of an *o*-hydroxyazo compound. On chroming, the shades produced by it are changed to dark violet. In a sodium bicarbonate solution of the diazo compound, which was allowed to stand until it no longer combined with azo-components, only 40 per cent. of the chlorine was found to have been converted into chloride, showing that in this case the reaction is very incomplete. *o*-Chloroaniline-*p*-sulphonic acid is readily obtained by heating the acid sulphate of *o*-chloroaniline to 160° C. for some hours at 20—30 mm. pressure. It is rather insoluble in water and forms a readily soluble sodium salt. On diazotising and combining with β-naphthol it forms a dyestuff very similar to Orange II. If the diazo-anhydride is treated with sodium carbonate for some time and then combined with β-naphthol, a dyestuff is obtained which yields impure orange shades only slightly altered by chroming, and which does not show the properties of an *o*-aminophenol derivative. In spite of this about 25 per cent. of the chlorine is split off. If the chlorine is replaced by a nitro group this latter is readily displaced. *o*-Nitraniline-*p*-sulphonic acid forms a diazonium anhydride which combines with β-naphthol to form a dyestuff yielding redder shades on wool than Orange II., which shades are stable to alkalis. If 1 mol. of the diazonium anhydride is added to a solution of 2·5 mols. of sodium bicarbonate, carbon dioxide is evolved and the liquid turns brown, *o*-hydroxydiazobenzene-*p*-sulphonic acid (sodium salt) being formed. This compound combines with β-naphthol to form a dyestuff which yields bright red shades on wool, which are sensitive to alkali, but are changed to fast dark violet shades on chroming.—E. F.

2.2′.4′-*Trihydroxyflavonol*; *Synthesis of* ——. E. Bonifazi, St. v. Kostanecki and J. Tambor. Ber., 1906, **39**, 86—91.

By the action of aromatic aldehydes on *o*-hydroxyacetophenones in presence of strong caustic soda solution, compounds containing the group $X<^{OH}_{CO.CH_2.CH(R)(OH)}$ are first obtained. These split off water immediately, forming either a chalkone, containing the group $X<^{OH}_{CO.CH:CHR}$ or a flavanone, containing the group $X<^{O—CH.R}_{CO—CH_2}$.

The direction in which condensation takes place was formerly considered by the authors to depend on the nature of the *o*-hydroxyacetophenone which was used. They now find that it also depends on the nature of the aldehyde. By the action of quinacetophenonemonomethylether on aldehydes, flavanones have always been previously obtained by the authors, but by the action of this ether on 1.3-dimethoxybenzaldehyde they obtain mainly 2′-hydroxy-5′.2.4-trimethoxychalkone. On treatment with acetic anhydride and dehydrated sodium acetate this forms a mixture of 2′-acetoxy-5′.2.4-trimethoxychalkone and 2-2′.4′-trimethoxyflavanone. The transformation into the trimethoxyflavanone may also be effected by boiling with alcohol and hydrochloric acid. On treatment with amyl nitrite and hydrochloric acid the trimethoxyflavanone forms *a*-isonitroso-2.2′.4′-trimethoxyflavanone, which dyes in orange shades on cobalt-mordant, in brown shades on copper-, and in yellow shades on uranium-, cadmium- and lead-mordants. When boiled with a mixture of glacial acetic acid and 10 per cent sulphuric acid this yields 2.2′.4′-trimethoxyflavonol, which dyes in yellow shades on alumina mordant. This compound forms 2.2′.4′-trihydroxyflavonol,

$$(OH)C_6H_3<^{O.C——C_6H_3(OH)_2}_{CO.C(OH)},$$

on boiling with strong hydriodic acid. This substance is a strong mordant dyestuff. On alumina mordant it dyes in yellow shades and on iron in olive-brown to black shades. This shows that the chromogenic group $—C:O \atop =C.OH$ is much more active in presence of hydroxyl groups in positions 2′ and 4′, and is of importance as it helps to explain the tinctorial properties of Morin, which, according to the authors is 1.3.2′.4′-tetrahydroxyflavonol.—E. F.

English Patents.

Phenylnaphthimidazole; Manufacture of new amino-hydroxylated derivatives of ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 11,759, June 5, 1905.

One or both of the sulphonic acid groups of phenylnaphthimidazoledisulphonic acids, which are in the naphthalene nucleus, may be replaced by hydroxyl groups by heating with alkali hydroxides to about 170° C., preferably in presence of water. The initial material, which has the general formula

$$(HO_3S)_2C_{10}H_4<^{N}_{NH}>C.C_6H_4.NH_2,$$

is obtained either by the reduction and condensation of a nitrobenzal derivative of a 1.2-diaminonaphthalenedisulphonic acid, or by treating with acids the nitrobenzal derivative of a nitrobenzeneazo-2-aminonaphthalenedisulphonic acid. In particular, the aminohydroxysulphonic acid of phenyl-1.2-naphthimidazole is claimed.—T. F. B.

Lakes (from azo dyestuffs); Production of red colour ——. J. Y. Johnson. From Badische Anilin und Soda Fabr. Eng. Pat. 82, Jan. 1, 1906. XIII*A*., page 224.

Dyestuff and process of making same; Anthracene ——. O. Bally, Mannheim, and H. Wolff. Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 811,471, Jan. 30, 1906.

See Sixth Addition of June 22, 1905, to Fr. Pat. 349,531 of 1904; this J., 1906, 14.—T. F. B.

Indigo; Process of chlorinating —— . A. Schmidt and E. Kronholz. Assignors to Farbwerke vorm. Meister, Lucius und Brüning, Höchst a/Main, Germany. U.S. Pat. 812,598, Feb. 13, 1906.

See Eng. Pat. 3182 of 1905; this J., 1905, 964.—T. F. B.

Dye [Anthracene dyestuff]; Yellow-green Anthraquinone ——. R. E. Schmidt and K. Thun, Elberfeld, Germany. Assignors to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 812,599, Feb. 13, 1906.

See Fr. Pat 354,076 of 1905; this J., 1905, 1061.—T. F. B.

Dye [Anthracene dyestuffs]. Green Anthraquinone ——. R. E. Schmidt, Elberfeld, Germany. Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 812,684, Feb. 13, 1906.

See Fr. Pat. 353,549 of 1905; this J., 1905, 1010.—T. F. B.

German Patents.

Aminobenzoylthiazol compounds; Process of preparing sulphonic acids of ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 163,040, March 6, 1904.

Sulphonic acids of aminobenzoylthiazol derivatives may be produced either by reducing the condensation products of nitrobenzoylhalides and thiazolsulphonic acids, or by condensing a nitrobenzoylhalide with a thiazol base, and subsequently sulphonating and reducing. The resulting amino compounds are of value for the production of dyestuffs; for instance, by diazotising on the fibre, and "developing" with β-naphthol, clear, fast orange shades are produced.—T. F. B.

Hydroxyanthraquinone aryl ethers; Process for preparing sulphonic acids of ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 164,129, March 13, 1904.

The aryl ethers of the hydroxyanthraquinones (Ger. Pat. 158,531; this J., 1905, 885) are sulphonated in the usual manner. Generally the sulphonic groups first enter the aryl nucleus, and then the anthracene nucleus. The sulphonation of the following ethers is described:—Anthrarufindiphenyl ether, chrysazindiphenyl ether, 1-amino-5-hydroxyanthraquinonephenyl ether (the sulphonic acid of this dyes wool orange shades), anthrarufindi-*o*-cresyl ether, and 1-phenylamino-5-phenoxyanthraquinone (the sulphonic acid of which gives red shades on wool).—T. F. B.

Anthracene series; Process for preparing hydrazine derivatives of the —— *[Anthracene dyestuffs].* Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 163,447, Aug. 18, 1904.

The diazo derivatives of aminoanthraquinones are converted by means of sulphites or bisulphites into the diazo sulphonic acids. These may be obtained in the solid form as sulphates, by dilution of their solutions in concentrated sulphuric acid. These diazosulphonic acids are reduced to the corresponding hydrazine derivatives by reduction; this may be effected by stannous chloride, zinc dust, hydrosulphites, &c., or by sulphurous acid or a sulphite, in which case the hydrazine-disulphonic acid, $C_6H_3(SO_3H)N(SO_3H)NH.SO_3H$, is obtained. Such hydrazine sulphonic acids are of value as dyestuffs, dyeing unmordanted wool in shades varying from yellowish-red to blue. The sulphonic acid group or groups may be eliminated by heating with dilute acids.—T. F. B.

Dyestuff; Process for preparing an [Azo] —— *especially suited for the manufacture of lakes.* Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 163,644, March 31, 1904.

Azo dyestuffs, from which very fast, bluish-red lakes are obtainable, may be prepared by combining diazotised 2-amino-1-naphthylmethanesulphonic acids with 2.3-hydroxynaphthoic acid. Similar dyestuffs are obtained from aniline, *m*-xylidine and *p*-nitraniline-*o*-sulphonic acid, but their lakes are fugitive in light.—T. F. B.

Hæmatoxylin; Process for preparing a solid dyestuff from ——. R. Haack. Ger. Pat. 162,726, Jan. 4, 1905. Addition to Ger. Pat. 162,010, July 1, 1904 (see this J., 1905, 1062).

In the process described in the principal patent, viz., of adding alkali nitrite to a concentrated solution of hæmatoxylin or logwood extract (*e.g.*, 30° B.), nitrous fumes are evolved, and hæmatein is produced. This is avoided by working with dilute solutions, *e.g.*, about 2° B., no nitrous fumes nor hæmatein being produced even if the solution is heated.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 179.)

3.2′.4′-Trihydroxyflavonol; Dyeing properties of ——. St. v. Kostanecki, V. Lampe and S. Triulzi. Ber., 1906, **39**, 92—96.

3.2′.4′-Trihydroxyflavonol, called by the authors Resomorin, stands in the same relationship to Morin (1.3.2′.4′-tetrahydroxyflavonol) as Fisetin (3.3′.4′-trihydroxyflavonol) does to Quercetin (1.3.3′.4′-tetrahydroxyflavonol.) The synthesis of Resomorin proved to be difficult, and the dyestuff could not be obtained in a chemically pure condition, but its dyeing properties were investigated and an acetyl derivative was purified and analysed. By the action of 1.3-dimethoxybenzaldehyde on resacetophenone-mono-methyl-ether (pæonol) in presence of sodium hydroxide, 2′-hydroxy-4′.2.4-trimethoxychalkone,

$$C_6H_3(OCH_3)(OH).CO.CH:CH.C_6H_3(OCH_3)_2,$$

is obtained. On boiling with a mixture of alcohol and 10 per cent. hydrochloric acid this is converted into 3.2′.4′-trimethoxyflavanone,

$$(CH_3O)-C_6H_3<\begin{matrix}O-CH-C_6H_3(OCH_3)_2.\\ CO.CH_2\end{matrix}$$

This is converted in the usual manner into an *a*-isonitroso-derivative, which dyes in yellow shades on cobalt mordant. This compound, on boiling for a short time with a mixture of glacial acetic acid and 10 per cent. sulphuric acid, yields 3.2′.4′-trimethoxyflavonol,

$$(CH_3O)C_6H_3<\begin{matrix}O\cdot C-C_6H_3(OCH_3)_2,\\ CO.C(OH\end{matrix}$$

which dyes on alumina mordant in yellow shades. On boiling with strong hydriodic acid this trimethoxyflavonol yields Resomorin, 3.2′.4′-trihydroxyflavonol,

$$(HO)C_6H_3<\begin{matrix}O-C.C_6H_3(OH)_2,\\ CO.C(OH)\end{matrix}$$

the dyeing properties of which closely resemble those of 2.2′.4′-trihydroxyflavonol and Morin; on alumina mordant fine yellow shades, and on iron mordant intense olive-brown shades are obtained. These results show that the dyeing properties of Morin are mainly due to the group —CO.C(OH)=, and not to the hydroxyl group in *peri*-position to the ketonic oxygen atom, which is not present in Resomorin.—E. F.

Cotton fabrics and yarns dyed with sulphide blacks; Investigation into the causes of the tendering of ——, *and some means for preventing it.* J. E. Pilling. J. Soc. Dyers and Col., 1906, **22**, 54—65.

Hanks of cotton yarn were dyed with seven different

sulphide dyestuffs, under the same conditions, and then treated for "fixing" purposes in six different ways. The hanks were next subjected to heating to 100° C. for 24 hours, and to 110°, 120°, and 130° C. for 12 hours. Subsequently their tensile strength was tested and the quantity of sulphuric acid formed, if any, determined. In most cases, but particularly in the case of the higher temperatures, the fibre was found to be greatly weakened and in all cases an appreciable quantity of sulphuric acid was formed. The hanks on which the dye had been "fixed" by means of copper salts were the weakest. In a second series of experiments the yarns were stored at the ordinary temperatures for different periods, varying from one to seven months. In these experiments, it is stated, the hanks fixed by exposure to the air or by chroming, gave better results than those fixed in other ways, showing either no, or very slight, weakening, and producing either no, or very small, quantities of sulphuric acid. The methods of after-treatment adopted were briefly: (1) exposing the wet washed-off yarn to the atmosphere for 24 hours; treating for 15 minutes at 60° C. in (2) a bath containing 3 per cent. of potassium bichromate and 6 per cent. of 20 per cent. acetic acid; (3) 3 per cent. copper sulphate solution; (4) 3 per cent. of potassium bichromate, 3 per cent. of copper sulphate, and 6 per cent. of 20 per cent. acetic acid; (5) 3 per cent. ferrous sulphate solution; (6) 3 per cent. chrome alum solution. The author concludes that the tendering observed was produced by the formation of sulphuric acid. A third series of experiments was undertaken to show that the sulphuric acid was formed solely from the dyestuff. Skeins were impregnated with a 1 per cent. solution of sodium sulphide and then treated by each of the six "fixing" processes without previous washing off. They were then heated to 100° C. and 130° C. for 12 and 24 hours respectively, but no sulphuric acid could be found, or only an infinitesimal amount. The formation of sulphuric acid it is, therefore, concluded, is due to oxidation of the dye-stuff molecule. In a further series of experiments the dyed yarns were subjected to the action of sulphurous acid for two hours (1) in the wet state, (2) dry. The author finds that sulphurous acid rots the dyed yarns under the conditions of his experiments, if they have been after-treated with copper or iron salts, especially in the moist state. The results obtained from each series of experiments are shown in tabular form. They show according to the author that no hard and fast rules can be laid down for the sulphide blacks; that they should not be treated alike, but each individual in the manner best suited to its properties, but that the use of copper salts for after-treatment must be avoided. Special attention is drawn to the fact that yarns treated with bichromate and acetic acid, or subjected to atmospheric influence after dyeing, kept practically in normal condition after many months' exposure. In general, to prevent tendering of goods dyed with sulphide blacks, the author recommends that the dyed goods should be impregnated with a carbonate or acetate; if this be impracticable, in the case of after-treatment with chrome is advantageous in the case of most dyestuffs.—H. L.

English Patents.

Cotton-seed hulls or other waste products containing fibrous materials; Processes and apparatus for treating ——. C. Knopf and Bremer Baumwoll-Werke, C. Knopf und Co. Hemelingen, Germany. Eng. Pat. 12,650, June 19, 1905.

THE waste materials are treated in suitable digesters, autoclaves or similar vessels, with solutions of reagents, which are capable of dissolving both the impurities of the fibres and the hull-residues, without however, noticeably attacking the fibres themselves. Suitable reagents are alkalis, alkaline earths, dilute acids, alkali sulphites and sulphates, and calcium, magnesium, potassium and sodium bisulphite. The treatment is effected under a pressure of about four to six atmospheres, and after the hulls have been sufficiently macerated or softened, the fibres to be recovered are mechanically separated therefrom by washing, beating, and sifting operations.—D. B.

Silk; Manufacture of artificial ——. G. Dietl, Berlin. Eng. Pat. 15,029, July 21, 1905.

SEE Fr. Pat. 356,323 of 1905; this J., 1906, 16.—T.F.B.

Evaporator for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, waste or spent dyes and the like, and concentrating the solids in the same; the evaporator being also applicable as a smoke washer. A. B. Lennox and T. Mackenzie. Eng. Pat. 8342, April 19, 1905. XVIII*B*., page 231.

Dye-water and similar effluents; Apparatus for purifying ——. W. McD. Mackey. Eng. Pat. 11,410, May 31, 1905. XVIII*B*., page 231.

United States Patent.

Formaldehyde-hydrosulphite and process of making same. E. A. Fourneaux, Assignor to H. A. Metz, New York. U.S. Pat. 812,124, Feb. 6, 1906.

A BASIC zinc formaldehyde-hydrosulphite, which is crystalline and can be dried in the air at 100° C. without decomposition, is prepared by the action of a "suitable alkali compound" on a solution of zinc hydrosulphite and formaldehyde. The corresponding sodium formaldehyde hydrosulphite is obtained by the action of sodium carbonate on the zinc compound. One part of the latter is capable of reducing about 1·5 parts of Indigo in the form of its sulphonic acid.—T. F. B.

German Patents.

Cotton and silk mixture; Process for preparing a —— which can be uniformly dyed. J. P. Bemberg, A.-G. Ger. Pat. 165,218, June 9, 1903.

ORDINARY cotton and silk "mixtures" cannot be uniformly dyed, the silk always taking a deeper shade than the cotton. It is proposed to weave together silk and mercerised cotton, the mercerisation being carried to such an extent, previously determined by experiment, that the cotton is dyed to the same depth as the silk by the particular dyestuff which is to be employed.
—T. F. B.

Aniline Black dyeings on wool; Process for increasing the fastness of ——. G. Bethmann. Ger. Pat. 161,263, Nov. 14, 1902. Addition to Ger. Pat. 130,309, Nov. 18, 1900.

THE Aniline Black dyeings on wool, produced by the process described in the principal patent (Eng. Pat. 21,236 of 1900; this J., 1901, 577), are rendered much faster by treatment with a 5 per cent. solution of an alkali carbonate; this neutralises the acid set free during the process, which is not the case when soaping is resorted to, as previously directed.—T. F. B.

Formaldehyde; Process of preparing a compound of —— containing sulphur. L. Cassella und Co. Ger. Pat. 164,506, March 25, 1904.

A SULPHUR derivative of formaldehyde, different from trithioformaldehyde and thiometaformaldehyde, is obtained by the addition of formaldehyde to an aqueous solution of an alkali sulphide. It is stable towards oxidising agents, and is inactive in the cold, but at higher temperatures, especially in presence of alkalis, it is decomposed, alkali sulphide being regenerated. It can be used in printing with sulphide dyestuffs, the finely divided dyestuff being mixed with the formaldehyde derivative, and printed on the fabric, which is then steamed.—T. F. B.

Cotton; Process for producing fast brown shades on ——. Badische Anilin und Soda Fabrik. Ger. Pat. 164,123, March 6, 1904.

ALTHOUGH fur, feathers, &c., can be dyed fast brown shades by impregnation with 1.5-dihydroxynaphthalene and exposure to air, cotton does not give good results by the process. Brown shades fast to light, washing and chlorine can, however, be obtained on cotton by impregnation with 1.5-dihydroxynaphthalene and subsequent steaming.—T. F. B.

Dyestuff ; Process for producing a fast, Bordeaux Red, Azo —— on the fibre. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 162,627, Aug. 11, 1904.

Fast, bordeaux-red shades are produced on the fibre by developing diazotised *m*-aminobenzeneazo-*m*-toluidine with β-naphthol. The dyestuff is formed much more readily than that from *p*-nitrobenzeneazo-*o*-toluidine (Ger. Pat. 155,396 of 1903 ; this J., 1905, 544). White discharges may be produced on the dyeings by means of formaldehyde-hydrosulphite compounds.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 180.)

Sodium tetrathionate and dithionate ; Action of potassium cyanide on ——. A. Gutmann. Ber., 1906, **39**, 509—513.

By the action of potassium cyanide on sodium tetrathionate in presence of alkali, potassium thiocyanate and sodium sulphate and sulphite are formed, according to the equation :

$$Na_2S_4O_6 + 2KCN + 2NaOH = 2KCNS + Na_2SO_4 + Na_2SO_3 + H_2O.$$

In this reaction, therefore, the tetrathionate apparently splits up according to the equation : $S_4O_6 = SO_2 + SO_3 + S_2$, whereas, by the action of sodium arsenite, it decomposes according to the scheme : $S_4O_6 = 2SO_2 + S_2 + O$, sodium sulphite, monosulphoxyarsenate and arsenate being formed (this J., 1905, 618). The explanation of this difference is probably that, in both cases, the tetrathionate gives up two atoms of sulphur to form thiocyanate and monosulphoxyarsenate respectively, but that in the reaction with cyanide the oxygen also given up oxidises the sulphite rather than the cyanide, since cyanates can only be obtained from cyanides in aqueous solutions by the use of very strong oxidising agents.

Sodium dithionate is not acted upon by potassium cyanide alone or in presence of sodium hydroxide, even on boiling.—A. S.

Potassium mercuric ferrocyanide. G. Ferneker. J. Amer Chem. Soc., 1906, **28**, 87—90.

Potassium mercuric ferrocyanide may be obtained as follows :—Fifteen to 20 grms. of mercuric chloride are dissolved in about 100 c.c. of a mixture of equal volumes of absolute alcohol and ether. Eight to 10 grms. of potassium ferrocyanide, dissolved in the least possible quantity of water, are then added, and the precipitate formed allowed to settle. The supernatant liquid is decanted, the precipitate is washed twice with the alcohol-ether mixture, then with cold water, and finally brought on to a filter, where it is washed with about one litre of water cooled to 0° C. The precipitate is once more washed with alcohol and ether and dried at a temperature of 100° C. When thus prepared the compound is a fine powder having only a very faint blue tinge. It has the formula $K_2HgFe(CN)_6$, is insoluble in water, but soluble to a considerable extent in potassium ferrocyanide solution, probably with the formation of a more complex compound.—W. P. S.

Arseniuretted hydrogen ; Reactions and methods of determining ——. H. Reckleben and G. Lockemann. XXIII., page 236.

Iodine ; Japanese ——. Chem. and Drug., Feb. 17, 1906.

The following figures show the increase in the exports of iodine and its compounds in Japan :—

	Quantity.	Values.
	lb	yen.
1905 (11 months)	57,214	250,819
1904	69,715	268,800
1903	29,753	101,174
1902	4,058	14,828

The chief kelp-producing districts in Japan are the province of Shima and the island of Hokkaido, but nearly all fishing districts produce a little. The industry is therefore more or less scattered along the coast of Japan, and is in the hands of many small producers, from whom the three largest firms procure their supplies. The annual production of iodine in Japan at present is estimated at about 200,000 lb., of which about 70,000 lb. is consumed there. [T.R.]

English Patent.

Ammonia ; Process of producing ——. K. Kaiser, Berlin. Eng. Pat. 26,803, Dec. 22, 1905. Under Int. Conv., Dec. 24, 1904.

Calcium turnings are heated in a clay or metal tube to about 500° C., and nitrogen and hydrogen are alternately passed through the tube, whereby calcium nitride is first formed, and then calcium hydride, the displaced nitrogen combining with the hydrogen passed through to form ammonia, which is collected from the effluent gases. The process may be started with calcium nitride or with calcium hydride, instead of with metallic calcium. (See also Fr. Pat. 350,966 of 1905 ; 1905, 801.)—E. S.

United States Patents.

Hydrochloric acid ; Manufacture of ——. I. L. Roberts, Brooklyn, N.Y. Assignor to Roberts Chemical Co., N.J. U.S. Pat. 807,640, Dec. 19, 1905.

Hydrogen and chlorine, in the proportion in which they combine to produce hydrochloric acid, and, preferably, as set free in the electrolysis of sodium chloride in a vessel provided with separate anode and cathode compartments, are conducted, each by its separate tube, to a mixing tube or chamber. This chamber is connected by tubing to the first of a series of receptacles containing water for absorption of the acid, provision for the continuous renewal and removal of which water is provided. The mixture of the gases is ignited, preferably at a point beyond the mixing chamber, into which the flame at once runs back, and in which the combustion goes on quietly and continuously, with the production of hydrochloric acid.—E. S.

Alumina ; Calcination of hydrated ——. A. R. Pechiney, Salindres. Assignor to Cie. des Prod. Chim. d'Alais et de la Camargue, Lyons, France. U.S. Pat. 811,433, Jan. 30, 1906.

See Fr. Pat. 349,707 of 1904 ; this J., 1905, 732.—T. F. B.

Tin ; Apparatus for producing compounds of ——. C. E. Acker, Niagara Falls, N.Y. Assignor to Acker Process Co., N.J. U.S. Pat. 810,897, Jan. 30, 1906.

The apparatus comprises a dissolving vessel for effecting the solution of tin in a solvent containing chlorine, a reaction tower, means for circulating the solution through the dissolving vessel and reaction tower, an electrolytic cell for the production of chlorine, with means for diluting the chlorine by steam, and for delivering it to the reaction tower. (See also U.S. Pats. 810,454—6 of 1906 ; this J., 1906, 180.)—E. S.

Efflorescence ; Apparatus for producing ——. K. Tsuji, Takaoka, Japan. U.S. Pat. 811,002, Jan. 30, 1906.

See Eng. Pat. 2346 of 1905 ; this J., 1905, 1108.—T. F. B.

French Patents.

Nitric acid ; Concentration of dilute ——. Chem. Fabrik Griesheim-Elektron. Fr. Pat. 358,373, Oct. 9, 1905.

Sodium polysulphate, $H_3Na(SO_4)_2$, is heated to about 110°—130° C., and a certain proportion of dilute nitric acid is incorporated with it, by aid of injection of air. From the mixture, concentrated nitric acid is distilled off and collected. The mass is then further heated to 250°—300°C. to expel the water taken up, after which the polysulphate is allowed to cool, the cooling process being aided by the injection of air, until the former temperature of 110°—130° is reached. A further addition of the dilute nitric acid is then made, and the process is renewed. The nitric acid may be distilled under a partial vacuum.—E. S.

Lime; Process for obtaining hydrated ——. J. Reaney, jun. Fr. Pat. 358,396, Oct. 10, 1905.

See U.S. Pat. 803,506 of 1905; this J., 1905, 1230.—T.F.B.

Gaseous mixtures, especially the oxygen and nitrogen of the air; Apparatus for mechanically separating ——. E. F. M. Farcot. Fr. Pat. 358,397, Oct. 10, 1905. I., page 211.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 181.)

Glass Industry of Bavaria. For. Off. Ann. Ser., No. 3526.

The manufacture of glass was impeded in 1904 by dry weather and lack of water power, especially in the Fürth district, the centre of the industry. The United States market, once all-important to the Bavarian glass industry, is being spoilt by inland competition and high duties, whilst the Canadian market has been lost entirely by the tariff war: the duty on Bavarian blown glass was formerly 20 per cent. *ad valorem*, Belgian crystal glass paying 25 per cent., but now the duty on German glass has been raised to 26⅔ per cent., whilst the duty on Belgian glass has been reduced to 10 per cent. If this state of affairs continues the Bavarian glass industry will soon be a thing of the past, having besides to fight against the keen competition of the Rhine provinces, Silesia, Saxony, Belgium and Bohemia. Fürth (Nuremberg) exported in 1890 to the United States glass to the value of 470,000*l.*, which sum fell to 118,533*l.* in 1903, and to 62,834*l.* in 1904. That district exported, up to 1904, mirrors to the value of about 12,500*l.* per annum to Canada, but since the new tariff and surtax amount to 26⅔ per cent. of the total value, the export trade to Canada is almost killed. Some works have ceased to manufacture mirrors, having turned to plate glass instead, whilst other works have stopped manufacturing entirely. The raw materials necessary to the glass industry have also increased considerably in price—acids and arsenic from 15 to 20 per cent., shellac even 300 per cent., &c., whilst the increase of the sale price was only from 5 to 12 per cent. This increase was partially rendered possible by the strike in Belgium. [T.R.]

United States Patent.

Silica glass; Manufacture of — —. J. F. Bottomley, Wallsend, R. S. Hutton, Manchester, and A. Paget, North Cray. U.S. Pat. 812,399, Feb. 13, 1906.

See Eng. Pat. 10,670 of 1904; this J., 1905, 670.—T. F. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 182.)

Cement: Relation of the volume weight of raw material to the output of a rotary kiln. W. H. Hess. J. Amer. Chem. Soc., 1906, **28**, 91—94.

The output of a rotary kiln in clinker is nearly twice as much when working on cement rock or limestone and clay, as when using a mixture of dry marl and clay, other conditions being the same. This difference is due to the varying volume weights of the materials. Results obtained by the author gave for marl alone a weight of 48·7 lb. per cubic foot; for chemically pure precipitated chalk, 32·7 lb.; and for natural commercial chalk, 70 lb. Using a small experimental kiln, it was found that a marl and clay mixture consuming 1125 lb. of coal per hour and producing 1600 lb. of cement, consumed 2760 lb. of cement mixture having a volume of 53 cubic feet. A kiln of the same construction, working on a cement rock mixture and consuming 1125 lb. of coal per hour and producing 3200 lb. of cement per hour, burned 52 cb. ft. of raw cement mixture per hour. The greater the weight of the ground raw cement mixture per cubic foot, the greater is the output of a kiln. The term "marl," used above, designates the lake deposits of Michigan, Canada, &c., which consist of about 90 per cent. of chalk, 5 per cent. of shell lime, and 5 per cent. of organic matter. As marl and chalk are too bulky, it is probable that in the future they will be replaced, for reasons of economy, by limestone and cement rock.—W. P. S.

English Patents.

Clay, or similar materials; Drying of various substances such as ——. T. M. Stocker, St. Austell, Cornwall. Eng. Pat. 2097, Feb. 2, 1905.

By means of suitably placed partitions, the hot gases in the flues beneath the drying chamber are forced to follow a zigzag or sinuous course, thereby ensuring a more even drying of the clay above.—A. G. L.

[*Pavements, blocks, tiles, &c.*] *Composition of matter.* S. G. Wightman, Washington, D.C., U.S.A. Eng. Pat. 19,622, Sept. 28, 1905.

From 6 to 10 lb. of iron oxide, preferably the "peroxide," is stirred into 100 lb. of melted resin, and the mixture added to 1000 lb. of powdered clay, sand, gravel, loam, &c., previously heated to 200° or 250° F. After thoroughly mixing it, the plastic mixture obtained is moulded and allowed to cool. The blocks obtained show a crushing strain of 2½ tons per sq. in., and remain rigid up to 160° F. When sand is used alone, 15 per cent. of the resin mixture should be used; clay or sand mixed with loam gives good results with 10 per cent. of resin.—A. G. L.

Cementing material and the manufacture of the same. R. Zellenka, Vienna. Eng. Pat. 5513, March 16, 1905.

The cementing material is made by melting sulphur, adding lampblack or other colouring matter, and ferruginous sand from iron foundries, or sand from iron or steel fettling, further heating the mixture until it becomes thick, and then allowing it to cool, with stirring, until it becomes thin enough to be poured into moulds. Before use the material must be heated to about 120° C., when it becomes a thin liquid, in which condition it is used for filling in joints between bricks, stone and iron or steel, &c.—A. G. L.

Cement kilns; Rotary ——. E. Newell and W. Fennell, Misterton, Notts. Eng. Pat. 9108, May 1, 1905.

The kiln is constructed of lengths of welded tube joined together by angle irons secured at the ends of the tubes, the angle irons being faced in a lathe and riveted or bolted together. The kiln has an increased external diameter at the firing end, the internal diameter being kept the same throughout, thus giving a greater thickness of refractory lining at the hottest parts.—A. G. L.

Bituminous substances, resins, oils, waxes and the like; Treating ——. E. Braschler-Kurtz, Zurich, Switzerland. Eng. Pat. 11,191, May 29, 1905. Under Int. Conv., June 2, 1904.

A solution of 90 parts of asphaltum in 200 to 300 parts of benzol is gradually introduced into a boiling solution of 3 parts of sodium soap and 2 parts of crude starch in 10 parts of water, the volatilised benzol being condensed and collected. The mixture is well stirred and allowed to cool with constant agitation, when a homogeneous mass is obtained which forms an even emulsion on diluting with water, and may be used for impregnating paper, bricks, &c., and for rendering roads dust-free. Other substances, *e.g.*, pitch, ozokerite, fats, oils, and balsams, dissolved in solvents such as carbon tetrachloride, &c., may be substituted for the benzol solution of asphaltum; gums, albumins, pectins, soluble silicates, &c., may replace the starch; and alkalis, alkaline earths, or borax may be substituted for the soap. The method of mixing may also be modified somewhat.—A. G. L.

United States Patents.

Roads; Process for tarring ——. L. Prósubert and G. A. Thubé, Nantes, France. U.S. Pat. 812,593, Feb. 13, 1906.

See Fr. Pat. 342,898 of 1904; this J., 1904, 1029.—T.F.B.

Cement; Hydraulic —— and process of making the same. C. D. Clark, Clifton, Ariz. U.S. Pat. 811,902, Feb. 6, 1906.

Ores with an aluminous silicious gangue are treated in concentrating or other mills, and the tailings from these are classified by hydraulic means. The tailings are pulverised and mixed with a calcareous substance, such as limestone, the mass being afterwards reduced to a powder, the mixture burnt to a clinker and the latter pulverised.—B. N.

French Patents.

Pavements, tiles and other building materials; Composition for ——. S. G. Wightman. Fr. Pat. 358 362, Oct. 9, 1905.

See Eng. Pat. 19,622 of 1905; preceding these.—T. F. B.

[*Hydraulic cement*]; *Silico-calcareous agglomerate.* C. de La Roche. First Addition of Feb. 22, 1905, to Fr. Pat. 350,340, Nov. 23, 1904.

In the present addition the agglomerate described in the original patent (see Eng. Pat. 25,884 of 1904; this J., 1905, 1233) is claimed as a hydraulic cement. Other substances, *e.g.*, magnesia, baryta, alumina, may also be added to the mixture.—A. G. L.

German Patent.

Slag; Process for the disintegration of molten blast-furnace ——. W. Lessing. Ger. Pat. 162 614, May 4, 1902. X., page 222.

X.—METALLURGY.

(*Continued from page* 185.)

Nickel and Cobalt Industry in 1905. Mining World, Jan. 27, 1906.

The world's production of nickel amounts annually to between 12,000 and 15,000 tons, Canada and the United States together contributing about two-thirds. The exports from New Caledonia in the 10 months ending with October, 1905, were 110,560 metric tons of nickel ore, and 7286 tons of cobalt ore. On this basis the year's exports may be estimated at about 122,000 tons of nickel ore and 8000 tons of cobalt ore.

Canada's output has been added to materially during the past year by reason of the energetic development of the mines in northern Ontario. There have also been interesting developments in the new district of Cobalt, near Lake Temiskaming, where cobalt-nickel arsenides occur in quantity in the rich silver ore. The average contents of some large shipments of this unique ore to New York showed 3·6 per cent. nickel, 7·3 per cent. cobalt, 31 per cent. arsenic, and 1257 oz. silver. The Ontario Government on Aug. 28 withdrew all lands in the townships of Coleman, Bucke, Lorrain and Hudson, comprising the silver-cobalt area, from sale or lease under the Mines Act, for the purpose of legislating so that a larger revenue may be realised from the mines. Existing rights of applicants, however, will not be interfered with. The Government has also granted to the Temiskaming and Northern Ontario Railway Commission full control over the silver cobalt locations on the right of way, as well as those on the townsite of Cobalt.

The production in Ontario, as reported by the Government for the six months ending with June, 1905, was 4671 tons of nickel, valued at 1,038,040 dols., and 65 tons of cobalt, valued at 80,560 dols. The year's output is estimated at fully 9250 tons of nickel and 125 tons of cobalt. A visit was made to the Sudbury nickel mines by the director of the India mint, for the purpose of securing a supply of nickel to be used in coining the new anna, valued at about 3 cents. The United States mines a small quantity of both nickel and cobalt, and in 1905 there was little change from 1904, when the nickel output of Madison county, Mo., was valued at 25,382 dols., and of cobalt at 89,708 dols.

The imports of nickel ore and matte into the United States in 1905 approximated 13,464 tons, free of duty, which is substantially more than was reported in 1904. Exports of nickel, nickel oxide and matte amounted to 9,698,000 pounds in 1905, which compares with 7,519,200 pounds in 1904, showing an increase of 29 per cent. [T.R.]

Tin Industry in 1905. Mining World, Jan. 27, 1906.

It is 18 years since tin sold at a higher level than in 1905. In 1888, when the world's consumption was 53,389 long tons, the top price in London was 170*l.* per ton; but the collapse of the French syndicate which had "rigged" the market brought the quotation down to 75*l.* per ton. In 1905 the world consumed 93,754 long tons, or 40,365 tons more than in 1888, reducing the visible supply to 13,451 tons on Dec. 31, 1905—a point which initiated a rise in price from 120*l.* 7*s.* 6*d.* to 165*l.* 12*s.* 6*d.* per ton. What share the United States took in establishing extraordinary prices for a metal which is produced at a comparatively low cost, by reason of cheap labour, will be understood when it is said that that country's consumption increased from 14,400 tons in 1888 to 40,144 tons in 1905.

Tin production of the World (long tons).

Carbon in steel; Determination of —— by direct ignition with red lead. C. M. Johnson. XXIII., page 236.

English Patents.

Iron ores; Process for agglomerating pulverulent ——. W. Schumacher, Osnabrück, Germany. Eng. Pat. 28,019, Dec. 21, 1904.

The ores are incorporated with finely-divided silica mixed with lime or calcium hydroxide, subjected to the action of steam and briquetted under pressure.—J. H. C.

Minerals; Wet separation of ——. H. L. Sulman and H. F. K. Picard, London. Eng. Pat. 1821, Jan. 30, 1905.

Small proportions of caustic or carbonated alkali, alkali sulphide or polysulphide, soluble soap, saponin or the like are mixed with the water employed, whereby its surface tension is diminished so as to cause permanent

frothing on agitation. The pulp prepared with the treated water is passed over a shaking table or vanner. —J. H. C.

Lead and like ores; Treatment of ——. A. J. Boult, London. From Soc. Anon. des Mines de Bormettes, and A. Lotti, Marseilles, France. Eng. Pat. 2861, Feb. 11, 1905.

SEE Fr. Pat. 346,527 of 1904; this J., 1905, 200.—T. F. B.

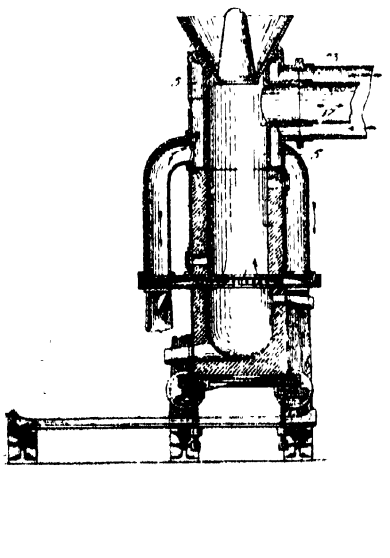
Alloys; Impts. in ——. Soc. Anon. "la Neo-Metallurgie," Paris. Eng. Pat. 3179, Feb. 15, 1905. Under Int. Conv., March 18, 1904.

SEE Fr. Pat. 341,639 of 1904; this J., 1904, 871.—T. F. B.

UNITED STATES PATENTS.

Converter. G. T. Walker, Washington, D.C. U.S. Pat. 811,006, Jan. 30, 1906.

THE converter communicates through an opening with a slag receptacle in close contact with it, air being as far as possible excluded from the slag-receptacle. The metal in the converter is agitated, and the slag and other impurities are driven to the top by means of a current of air or other gas, introduced below the surface of the metal through a double series of tuyères. Through another double series of tuyères air is forced against the surface of the metal in the converter, and drives the slag and other impurities into the slag-receptacle.—A. S.



Crucible furnace. E. Hausmann, Cologne, Germany. U.S. Pat. 811,219, Jan. 30, 1906.

SEE Eng. Pat. 16,087 of 1905; this J., 1906, 78.—T. F. B

Furnace; Roasting ——. F. Klepetko, New York. U.S. Pat. 811,643, Feb. 6, 1906.

THE furnace consists of a number of superposed hearths through which passes a rotating hollow shaft having hollow arms extending into the hearths. The shaft is divided by a longitudinal partition into two conduits communicating with each other at the top of the shaft. These conduits are divided into compartments by transverse partitions, and pipes lead from the compartments into the hollow arms. A cooling medium is caused to circulate through the whole apparatus, entering at the bottom of one conduit, and passing in succession up through each compartment and hollow arm on one side of the central partition, and then down in like manner through the compartments and hollow arms on the other side of the partition, finally escaping at the bottom of the second conduit.—A. S.

Furnace; Smelting ——. A. R. Partridge, San Francisco, Cal. Assignor to The Vencedora Mine Equipment Co., California. U.S. Pat. 812,083, Feb. 6, 1906.

THE upper part of the furnace is constructed with double walls, a hot-air space, 5, being thus formed. The air-inlet pipe, 23, surrounds the outlet pipe, 17, leading to the stack, and communicates with the hot-air space. An exhaust fan is placed in the outlet-pipe, and a fan-blower in the inlet-pipe.—A. S.

Ore or flue-dust; Sintering comminuted ——. G. L. Davison. Assignor to American Sintering Co., Chicago, Ill. U.S. Pat. 811,040, Jan. 30, 1906.

THE dry ore or flue-dust is mixed with about 1 per cent. of dry comminuted "fluor," and the mixture is passed gradually through a rotary furnace, wherein it is heated to a temperature which causes the mixture to partially fuse.—A. S.

Ores; Process of recovering values from sulphide ——. F. C. Pohlé, Reno, Nev. U.S. Pat. 811,085, Jan. 30, 1906.

SULPHIDE ores containing gold, silver and base metals are mixed with a chloride and roasted in an oxidising atmosphere, the vapours produced being forced together with the products of combustion, through condensing and cooling arrangements, where any metallic vapours are recovered. The roasted ore is cooled, leached with water to remove soluble substances, and then leached with a solution of an alkali cyanide to dissolve the gold and silver.—A. S.

Nickel-copper alloys; Manufacture of ——. A. Monell, New York. U.S. Pat. 811,239, Jan. 30, 1906.

AN ore containing the sulphides of nickel and copper is smelted, the resulting matte is bessemerised, the product is roasted to convert the metals into oxides, and the latter are reduced in order to obtain directly a malleable nickel-copper alloy.—A. S.

Aluminium; Means for soldering ——. A. W. King. Assignor to C. Rogers, London. U.S. Pat. 811,725, Feb. 6, 1905.

SEE Eng. Pat. 3589 of 1905; this J., 1905, 804.—T. F. B.

Iron sponge; Method of manufacturing ——. G. Gröndal, Djursholm, Sweden. U.S. Pat. 812,174, Feb. 6, 1906.

SEE Fr. Pat. 330,763 of 1903; this J., 1903, 1091.—T.F.B.

Steel; Melt or bath for hardening ——. S. N. Brayshaw, Hulme. Assignor to G. Nash, New York. U.S. Pat. 812,178, Feb. 13, 1906.

SEE Eng. Pat. 12,816 of 1904; this J., 1905, 803.—T. F. B.

GERMAN PATENTS.

Steel in hearth furnaces; Production of slags poor in metallic oxides in the manufacture of mild ——. Elektrostahl G.m.b.H. Ger. Pat. 163,519, July 23, 1904.

CLAIM is made for the addition to the slag, as it forms, of suitable quantities of calcium carbide or silicon carbide, or a mixture of the two substances. The metallic oxides are reduced, the metals re-dissolving in the molten metal in the furnace, and a calcium silicate slag is produced, which, it is stated, has little action on the furnace lining. —A. S.

Ores and metallurgical products of all kinds; "Sulphatisation" of —— by fusion with sulphates. E. Enke. Ger. Pat. 163,410, Nov. 18, 1904.

THE ore is fused with an alkali bisulphate, preferably sodium bisulphate, or with ferrous sulphate, or a mixture of the two substances. The air is excluded and the temperature is maintained at a point at which only the ferrous sulphate added or formed in the process, is decomposed. —A. S.

Alloys of metals of different specific gravity; Manufacture of ——. A. Mahlke. Ger. Pat. 163,411, Nov. 22, 1904.

PIECES of the lighter metal are placed on the bottom of a crucible without touching the walls, and are packed around and above with pieces of the heavier metal. A quantity of the fused heavier metal is then poured into the crucible

so that the light metal is completely protected from the atmosphere. After adding a further quantity of the heavier metal, if required, the mixture is fused.

It is stated that by this process alloys containing relatively high percentages of magnesium can be produced, and also hard lead containing more antimony than that obtained by the usual methods.—A. S.

Slag; Process for the disintegration of molten blast-furnace ——. W. Lessing. Ger. Pat. 162,614, May 4, 1902.

The molten slag is fed on to the corrugated surface of a long, horizontal rotating drum. Lime or other substances may be added to the slag before it reaches the drum, or may be fed on to the drum with it.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 188.)

(*A.*)—ELECTRO-CHEMISTRY.

Electrolytic reduction; Cathodic potential and —— *in sulphuric acid solution.* J. Tafel. Z. Elektrochem., 1906, **12**, 112—122. (See also this J., 1901, 48.)

The present communication gives the general conclusions which the author has arrived at as a result of his extended studies on the reducibility of difficultly reducible organic compounds with lead cathodes in sulphuric acid solution. As special cases the conversion of strychnine into tetrahydrostrychnine and of caffeine into deoxycaffeine have been considered. The progress of the reduction and the current efficiency of the process were followed by gas measurements. It was found first with caffeine, and confirmed later with a whole series of substances, that lead, mercury or cadmium electrodes are essential for the reaction. Direct measurements prove the close connection between the high "over-voltage" which these metals exhibit in sulphuric acid and their power of allowing the reduction to occur. In the course of the work various disturbing influences have been detected, and in many cases could be ascribed to minute quantities of metallic impurity. The lowering of the cathodic potential and the diminution or cessation of the process of reduction are closely connected with a chemical alteration of the surface of the cathode. In this respect mere traces of platinum are exceedingly deleterious. The author favours the view that the surface of the cathode in the active condition consists of a metallic hydride which is destroyed by oxidising agents or by platinum, leaving the less active metallic surface. In both cases, after a shorter or longer time, under the action of the current, the active condition is restored.

In the case of caffeine, below a cathodic potential of 1·6 to 1·7 volts, with current densities varying from 0·04 to 0·125 ampère per sq. cm., reduction does not occur.

Succinimide is reduced to pyrrolidone, but upon spongy lead cathodes the current efficiency attained 67—68 per cent., whilst on polished lead under otherwise similar conditions only 8·6 per cent. was reached. Here definite evidence of the catalytic influence of the metal in increasing the reducing power of the discharged hydrogen ions was obtained.

When the effect is considered of the substance undergoing reduction and its products, upon the cathodic potential, the matter becomes complicated. Both the depolarisation, tending to diminish the potential, as also the specific action of some of these substances in raising the potential, have to be dealt with.—R. S. H.

English Patent.

Furnaces; Electric resistance ——. J. F. Bottomley, Wallsend-on-Tyne, and A. Paget, North Cray, Kent. Eng. Pat. 9522, May 5, 1905.

An electric current is passed through carbon or graphite plates forming an inner lining to the cover of the furnace. The material to be treated is supported on a movable hearth immediately below these plates and is thus heated by radiation. The object is to offer an extended heating surface, the temperature of which can be limited to any desired extent. Means are provided for excluding air and for the admission of material to the hearth.—R. S. H.

Water; Apparatus for the [electrical] purification of ——. J. S. Zerbe. Eng. Pat. 9216, May 2, 1905. XVIII*B.*, page 231.

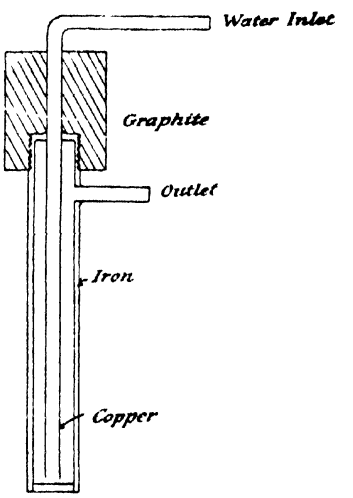
Flour, grain, rice and other substances; Electric purifier for use in purifying ——. J. L. Lawson. Eng. Pat. 13,907, July 6, 1905. XVIII*A.*, page 231.

United States Patents.

Hydrochloric acid; [Electrical] Manufacture of ——. L. L. Roberts, Assignor to Roberts Chem. Co. U.S. Pat. 807,640, Dec. 19, 1905. VII., page 218.

Lead oxide; Process of making hydrated —— *[electrolytically].* J. H. Bridge, New York, and C. Ellis, Boston, Mass. U.S. Pat. 811,552, Feb. 6, 1906.

A hot concentrated aqueous solution of purified sodium chloride is electrolysed, using lead anodes, and the products of the electrolysis are allowed to mix, so as to form a precipitate of hydrated lead oxide and re-form the original electrolyte. The insoluble lead oxide is removed and the electrolyte again returned to the electrolytic cell.—B. N.



French Patents.

Incandescence electric lamps; Manufacture of ——. Siemens und Halske A.-G. First Addition, dated Sept. 14, 1905, to Fr. Pat. 321,412, May 26, 1902. II., page 213.

Incandescence electric lamps; Manufacture of metallic conducting bodies [tungsten and molybdenum] for ——. A. Jusk, F. Hanaman, Ver. Elektrizitäts A.-G., H. Landesberger and J. Salzmann. Fr. Pat. 358,272, Oct. 4, 1905. II., page 213.

(*B.*)—ELECTRO-METALLURGY.

Calcium; Preparation of metallic —— *by electrolysis.* S. A. Tucker and J. B. Whitney. J. Amer. Chem. Soc., 1906, **28**, 84—87.

The apparatus employed consists of a graphite crucible turned from an Acheson electrode. This crucible forms the anode and the cavity for the electrolyte is 10 cm. in diameter by 10 cm. deep. The bottom of the crucible is about 3 mm. thick and is cooled by a coil of copper tube through which water is circulated. A layer of fluorspar is placed on the bottom, and on this is poured fused calcium chloride until the crucible is nearly full; the

water-cooled cathode shown in the illustration is then immediately lowered into the crucible and the current turned on. Preliminary experiments showed that the temperature of the apparatus must be kept constant just below the point at which the metallic calcium begins to oxidise, namely, 720° C. The yield of metal is most satisfactory if the temperature be kept at 715° C. The current should be kept between 125 and 150 ampères. As the metal forms, the cathode is gradually raised by means of a wheel arrangement, and, when the rod of calcium becomes so long that the cooling effect of the water circulation is lost, the metal is removed and the process resumed by bringing the cooled iron in contact with the electrolyte. —W. P. S.

Metals; Some electrical measurements on ——. C. E. Fawsitt. Roy. Soc. Edin., Proc., 1906, **26**, 1—6.

If two rods of the same metal be inserted in a solution of a salt of that metal, and if one of the rods be in the soft or annealed condition, whilst the other is in the hardened condition, then the hardened rod is the negative and the soft the positive element of the cell. With other electrolytes the results are similar, but the measurements less definite. (Compare G. T. Beilby, this J., 1904, 788.) —R. S. H.

English Patent.

Electroplating tubes or other hollow articles; Apparatus for ——. L. Potthoff, Brooklyn, U.S.A. Eng. Pat. 6790, March 30, 1905.

See U.S. Pat. 786,776 of 1905; this J., 1905, 504.—T.F.B.

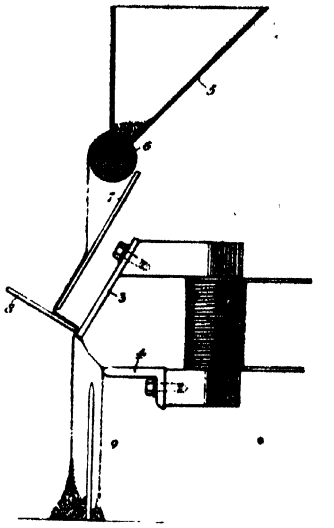
United States Patents.

Electrodeposition. W. C. Arsem, Schenectady. Assignor to General Electric Co., New York. U.S. Pat. 811,759, Feb. 6, 1906.

See Eng. Pat. 18,840 of 1904; this J., 1905, 896.—T.F.B.

Iron ore; Magnetic separation of —— and apparatus therefor. G. Gröndal, Djursholm, Sweden. U.S. Pats. 812,170 and 812,172, Feb. 6, 1906.

The separator comprises a stationary electro-magnet, "having a pole-piece formed with an elongated edge," which pole-piece is surrounded by a rotating drum constructed of magnetically indifferent material, but with iron lamellæ on its outer surface. Below, but near the drum, is a tank or chamber divided into two compartments by a partition reaching nearly to the top. A liquid containing the ore in suspension is fed in at the bottom of one compartment, and flows over the partition into the second compartment, thus passing near to the surface of the rotating drum. The non-magnetic particles, which are drawn to the surface, but not out of the liquid, escape through an overflow channel, whilst the magnetic particles of ore are drawn out of the liquid and discharged into another channel.—A. S.



Ore separator; Magnetic ——. G. Gröndal, Djursholm, Sweden. U.S. Pats. 812,171 and 812,173, Feb. 6, 1906.

See Fr. Pat. 348,535 of 1904; this J., 1905, 505.—T.F.B.

French Patent.

Separator for [ores]; Magnetic —— and an electro-magnet for the same. The Edison Ore Milling Syndicate, Ltd. Fr. Pat. 358,262, Oct. 4, 1905.

The electro-magnet, a side view of which is shown in the diagram, is characterised by the pole pieces, 3, 4, being much longer than the diameter of the magnet. The ore is fed from the hopper, 5, over the distributing roller, 6, on to the inclined table, 7. Its descent is arrested by the inclined plate, 8, so that when it comes under the influence of the magnet it is moving very slowly. The magnetic particles are attracted by the lower polar piece, 4, and collect on one side of the division wall, 9, whilst the gangue falls by gravity on the other side. In practice a number

of separators are arranged one above the other, the tailings from one being conveyed to the next lower one, and so on.—A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 188.)

Olive Oil; Export of —— from South Italy. For. Off. Ann. Ser., No. 3530.

The export of olive oil in the past year is the lowest recorded in the last quinquennial period, the cause being the very poor crop of 1904—5. In the United Kingdom, to which a large portion of the yield was exported, great competition arose from the Spanish and other oils in the British markets. Spain was, however, the chief competitor. Russia, usually an important customer, only took a very small amount.

The following table shows the exports of olive oil from Gallipoli from Jan. 1 to Dec. 31, 1905, as compared with the years 1901—4:—

Mercury and iodine; Determination of —— in antiseptic soaps. A. Seidell. XXIII., page 236.

English Patent.

Detergent; Manufacture of a ——. W. E. Heys, Watford, Herts. Eng. Pat. 17,777, Sept. 2, 1905.

Nine lb. of commercial oleine are emulsified with a solution of 1 lb. of ammonium chloride in 20 lb. of water,

in a suitable mixing apparatus. 8 lb. of soda lye (90·6° T.) and 6 lb. of water are then added and the whole well mixed for a few minutes, when 40 lb. of sodium carbonate and 9 lb. of sodium bicarbonate are successively added. Less water and sodium carbonate may be employed, and the bicarbonate may be omitted. Instead of ammonium chloride, ammonium carbonate may be used, in which case 5 lb. of common salt are finally added to the mixture. When the doughy mass at first formed begins to break up, it is removed from the mixer, granulated, dried and passed through a disintegrator, or compressed in suitable moulds. —W. P. S.

FRENCH PATENT.

Unsaturated compounds; Process for transforming —— into saturated compounds. C. Dreymann. Fr. Pat. 358,212, Oct. 2, 1905.

UNSATURATED compounds may be converted, by heating with a condensing agent, preferably sulphuric acid, into saturated compounds, the condensation product being distilled either dry, or by means of superheated steam, or in the vapour of some indifferent substance; the product may also be saponified previous to distillation. For example, 5 parts of olein are heated with 1 part of concentrated sulphuric acid for three hours, at about 50° C.; the product is washed with water, heated in an autoclave with 2 per cent. of its weight of lime, superheated steam being also introduced, and finally distilled by means of superheated steam. A solid, saturated fatty acid is stated to be produced. Turpentine, fatty esters, resins, and the acids contained in petroleum may also be converted into saturated compounds by similar means.—T. F. B.

Lacquer or varnish. J. P. Ihart, New York, N.Y. U.S. Pat. 811,563, Feb. 6, 1906.

THE fraction of the distillate from oil-gas tar, passing over below 200° C. is mixed with one of the chlorides of tin, bismuth, antimony or aluminium.—B. N.

GERMAN PATENTS.

Lacquer; Matt ——. F. Goldscheider. Ger. Pat. 165,141, Feb. 26, 1904. Under Int. Conv., March 13, 1903.

STARCH is added to an ordinary spirit varnish.—A. S.

Linseed oil for the preparation of varnish; Purification of ——. C. Niegemann. Ger. Pat. 163,056, March 8, 1904.

AFTER cooling the oil to its solidifying point, the temperature is allowed to rise again until the oil becomes capable of being filtered. At this temperature (below 0° C.) the separated albuminous impurities are removed by filtration.—A. S.

(C.)—INDIA-RUBBER, Etc.

Rubber; Action of atmospheric oxygen on Para ——. E. Herbst. Ber., 1906, **39**, 523—525.

PARA rubber (6·004 grms.), purified by the method given by Harries (Ber., 1905, **38**, 1198), was dissolved in benzene (600 c.c., b. pt. 80°—85° C.) and the solution heated for 140 hours under a reflux condenser, while a current of dry air, free from dust, was passed through it. The benzene lost by evaporation was renewed from time to time. The solution gradually became yellow, and a small quantity of a yellowish-grey resinous substance, practically insoluble in alcohol, petroleum ether, glacial acetic acid and carbon bisulphide, separated from it. The rubber had become completely oxidised, and on distilling off the benzene, a syrupy mixture of resinous bodies (6·735 grms.) was obtained. From this residue the following substances were separated: (1) A clear, light-brown syrup (5·818 grms.), soluble in petroleum ether (b. pt. 60°—70° C.), possessing a characteristic aromatic odour, and having the composition $C_{10}H_{16}O$. (2) An amorphous, pale yellow, friable mass (0·115 grm.), with a faint aromatic odour, having the composition $C_{10}H_{16}O_3$, precipitated from the benzene solution by petroleum ether. (3) A dirty yellow viscous mass, solidifying *in vacuo* to a hard, brittle, vitreous mass (0·15 grm.), resembling shellac. This substance was obtained by concentrating the mother liquors from substance (2) and precipitating with a large excess of petroleum ether; it also had the composition $C_{10}H_{16}O_3$. Substances (2) and (3) are similar in composition to Spiller's resin (J. Chem. Soc., **3**, [2], 44).—E. W. L.

Rubber; Solubility of vulcanised —— in pyridine. R. Ditmar. Gummi-Zeit., 1906, **20**, 441.

THE author confirms the statement of W. Esch (Gummi-Zeit., 1906, **20**, 324) that pyridine dissolves notable quantities of vulcanised rubber, on prolonged action at an elevated temperature. Pyridine, therefore, cannot be used as a solvent for the extraction of tar, pitch, and asphaltum, in the analysis of rubber goods.—E. W. L.

Rubber-resins; Ethyl acetate as a solvent for ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 441.

EXTRACTION with ethyl acetate removes a further small

quantity of resin from acetone-extracted, raw Pará rubber. In using ethyl acetate as a solvent for resins in rubber analysis, however, account must be taken of the fact that small quantities of the rubber itself are also dissolved by it, and carried into the extract, from which they must be precipitated by means of alcohol (and their weight deducted from the total loss in weight of the rubber on extraction).

The action of ethyl acetate on the rubber is to render it very plastic; in this condition it can be readily shaped into various objects, which retain their form after the evaporation of the solvent, the rubber losing its plasticity and recovering its original properties.—F. W. L.

XVI.—SUGAR, STARCH, GUM, Etc.

Lichens; The carbohydrates of the ——. A. Ulander and B. Tollens. Ber., 1906, **39**, 401—409.

As a result of these investigations, the lichens may be divided into two main groups according to the behaviour of their constituent carbohydrates towards boiling water and acid hydrolysis.

(1) *Iceland moss group.*—This group includes the lichens *Cetraria islandica* (Iceland moss), *Evernia prunastri*, *Usnea barbata* and *Cornicularia aculeata* and the fungus *Bulgaria inquinans*. From the members of this group, after purification with potassium carbonate, boiling water extracts amorphous, gelatinous carbohydrates similar to lichenin. The lichenin from Iceland moss is not identical with the evernin from *Evernia*, since the former is optically inactive, whilst the latter is strongly dextrorotatory. All these soluble carbohydrates readily yield dextrose on hydrolysis. The residues from the aqueous extraction are easily hydrolysed by boiling with dilute sulphuric acid, and yield principally dextrose, together with small quantities of mannose and galactose.

(2) *Reindeer moss group.*—This group comprises *Cladonia rangiferina* (reindeer moss), *Stereocaulon pascale* and *Peltigera aphtosa*. These lichens yield no appreciable quantities of carbohydrates soluble in boiling water. The carbohydrates of this group are hydrolysed by acids with far greater difficulty than those of the first group. The products of hydrolysis consist principally of mannose and galactose, with only small quantities of dextrose. The quantitative relations of the sugars obtained by the hydrolysis of the carbohydrates of both groups vary considerably in the different members. Small quantities of furfural and methylfurfural were obtained from both groups of lichens. The residue resisting hydrolysis appears to consist of cellulose.—J. F. B.

Starch factories; Industrial control of the yield of starch in potato ——. E. Parow. Z. Spiritusind, 1906, **29**, 51—52.

THE author describes the method to be followed for checking the yield of starch in the factory, and for tracing the sources of loss, if any. Samples of 60 kilos. each are taken five times in the course of the day from the crude potatoes as they enter the system. These are thoroughly washed, allowed to dry over-night and weighed the next morning. The average weight enables the correct weight of clean, raw material taken into work to be calculated. Similarly five samples of potatoes are taken during the day and the average percentage of starch is determined in them by means of the potato balance. After the potatoes have been rasped and pulped, the starch is separated and collected in the settling tank. After washing in the mechanical washer, the starch is collected in bags and drained. The starch suspended in the wash waters is passed through sieves and settled on tables, and the starch deposited, is drained and weighed with the main yield. The pulps are pumped into a reservoir and measured out in a tared box; five weighings of this when full give the average weight of pulps produced. Determinations are made in the laboratory of the percentage of water in the moist starch; and the percentage of starch in the pulps: (*a*) the starch which might have been recovered by further washing, and (*b*) the starch enclosed in the pulps. Finally, all the effluent waters are gauged at the point of exit from the factory and the quantity of starch suspended in an average aliquot sample of them is determined. The following figures show the results actually found in the case of a starch factory working satisfactorily:—Weight of cleaned potatoes, 191 cwts., containing 1850·8 kilos. of dry starch as determined by the balance. Dry starch obtained, 1404·3 kilos.; in the pulps: (*a*) capable of extraction, 22 kilos.; (*b*) enclosed, 324·5 kilos.; in the effluent waters, 14·6 kilos.; total 1765·5 kilos.; errors and unaccountable losses, 83·3 kilos. = 4·61 per cent. of the total starch.—J. F. B.

Sugars, Specific gravities of solutions of the principal ——. O. Mohr. Z. Spiritusind., 1906, **29**, 25—26.

THE existing data relating to the specific gravities of solutions of the different sugars at different concentrations are of the most diverse nature so far as the temperatures of observation and the units of volume are concerned. The observations have been made indiscriminately at 15°, 17·5° and 20° C., and the units are referred to water either at the same temperatures or at 4° C. Some of the tables show the contents of the solutions in percentages by weight, others show the number of grms. of sugar per 100 c.c. The author has re-calculated and co-ordinated the most reliable tables for the principal sugars, *viz.*, dextrose, levulose, invert sugar and maltose, comparing them with the German official normal tables for cane sugar. He shows the percentage by weight and the concentration in grms. per 100 c.c. for each of the sugars, with the corresponding specific gravities (either at 17·5°/17·5° or at 20°/4°), of cane sugar solutions of the same concentrations at the same temperature and the percentage by weight of cane sugar in solutions of the same specific gravities.

The columns marked * represent original observations, the others are calculated.

The tables show that the specific gravities of the solutions of the various sugars are not identical with those of cane sugar of the same concentrations. Levulose, invert sugar and maltose solutions have higher specific gravities than the corresponding solutions of cane sugar, whilst those of dextrose have lower specific gravities. The differences at medium concentrations are not very great, and amount only to a few units in the fourth place of decimals, so that the use of the cane sugar tables for the determination of other sugars involves an error of only 0·1 per cent. and is very convenient. The comparison of the tables indicates that the hydrolysis of cane sugar to invert sugar and of maltose to dextrose is accompanied by a considerable contraction in volume.—J. F. B.

Gum; Export of —— from Senegal. Bd. of Trade J., Feb. 15, 1906.

THE total export of gum from Senegal in 1904, the last year for which statistics have appeared, was 2,370,031 kilos., valued at 44,835*l*. This was divided as follows:—Hard gum, 1,842,610 kilos., from the region north of the River Senegal, and 484,095 kilos., from the Soudan and Senegal proper; friable gum, 37,396 kilos., from all parts; dust and damaged gum, 5,930 kilos., from all parts. An export duty of 1 franc 50 centimes per kilo. was formerly levied, but was removed in May, 1905, so that there are now no royalties or export duties on gum. At least three-fourths of the gum is brought by caravans to the various posts on the River Senegal, from which they are taken to St. Louis by river transport of various kinds, and thence embarked for Europe. Since the re-opening of the Egyptian Soudan, the Senegal gum trade has been dwindling away, and is now looked upon as of quite secondary importance.

UNITED STATES PATENT.

Sugar; Method of making maize ——. F. L. Stewart, Murraysville, Pa. Assignor to S. E. Gill, Pittsburg, Pa. U.S. Pat. 811,523, Jan. 30, 1906.

THE ears are separated from the growing maize whilst they are still immature, and are at the stage of growth when the "ear is in the milk and the protruding silk is dead." The growth of the plant is then continued, when an increase of the sugar content of the stalk takes place. Finally the juice is extracted, clarified and converted into sugar or syrup.—J. F. B.

FRENCH PATENTS.

Sugar juices; Clarification of —— by means of hydrosulphurous acid or its salts. F. Schiller and K. Herbst. Fr. Pat. 358,296, Oct. 5, 1905.

HYDROSULPHUROUS acid or one of its salts, such as the

aluminium or calcium salt, is added to the crude sugar cane or beet roots during or after the extraction of the juice, whilst the latter is still in the undefecated, acid condition. The base of the hydrosulphite combines with the organic acids of the juice, precipitating them together with a considerable proportion of the albuminoids, and other non-sugar constituents. At the same time the hydrosulphurous acid, which is said to have no inverting action on the sugar, reduces the colouring matters of the juice.—J. F. B.

Starch and dextrin; Manufacture of phonograph records from ——. Comp. gen. de Phonographes, Cinematographes et Appareils de Precision. Fr. Pat. 358,366, Oct. 9, 1905.

For moulding records in the form of discs or cylinders, potato, farina or other starch, or commercial dextrin, is introduced into the mould in a dry, pulverulent condition. The mass is then subjected in the mould to a pressure of about 200 kilos. per sq. cm. During the action of this pressure the temperature of the mass is raised by means of steam to 110°—120° C. Under the combined action of heat and pressure, the starch is modified and becomes fused to a hard, horny mass, which retains the impression of the mould.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 194.)

Fermentation; Studies in ——. 1. *Chemical dynamics of alcoholic fermentation by yeast.* A. Slator. Chem. Soc. Trans. 1906, **89**, 128—142.

The author describes a new method for measuring the velocity of fermentation, over very small ranges of the reaction, by observing the increase of pressure developed in short intervals of time by the carbon dioxide evolved. A bottle of about 150 c.c. capacity is connected with a manometer by a piece of thick rubber tubing. 50 c.c. of the solution of sugar, yeast and nutrient salts are introduced into the bottle and the latter is placed in the thermostat, the apparatus is evacuated through a side tube provided on the short arm of the manometer, and the level of the mercury is read off. The change of pressure caused by the evolution of carbon dioxide is registered on the scale of the manometer, and serves as a very sensitive measure of the relative progress of the fermentation. Experiments made in this manner at 30° C. showed conclusively that when the quantity of yeast was increased, other conditions being constant, the velocity of fermentation was proportional to the concentration of the yeast. In a second series of experiments, the quantity of yeast was maintained constant whilst the concentration of the sugar (dextrose) was varied between 0·20 and 20·0 grms. per 100 c.c. It was found that, between the limits of 0·50 and 10·0 grms. of dextrose per 100 c.c., the velocity of fermentation was very nearly independent of the concentration of the sugar, a maximum point being, however, just discernible at about 5 per cent. of sugar. Below 0·5 per cent. of sugar the velocity of fermentation was influenced by the concentration of the sugar, but was never really proportional to it, whilst above 10 per cent. the excess of sugar exerted a distinct retarding influence. The above observations are most simply explained by the formation of a compound between the enzyme and the sugar by diffusion of the latter into the cell, and the velocity which is measured experimentally is the rate of decomposition of this compound. The temperature-coefficient of the reaction of fermentation is large and varies with the temperature; from the tables given in the paper, the ratios of $V_{15}°/V_{5}° = 5·6$ and $V_{40}°/V_{30}° = 1·6$ may be cited as illustrations. The temperature quotients for every 5° from 5° to 40° C. form a series of numbers which seem to be characteristic of the enzyme zymase, being independent of the concentration of yeast and dextrose, the type of yeast, the presence or absence of nutrient salts and of inhibiting agents.

The initial rates of fermentation of dextrose, levulose, sucrose and maltose are in the ratios of 1:0·92:1·05:0·9. Sucrose and maltose show constant values for the velocity of fermentation within a few minutes of the start, indicating that sufficient of the disaccharide is hydrolysed almost instantaneously for the fermentation to attain its maximum velocity. The addition of lactic acid produced no change in the velocity of fermentation, and the author concludes that it is very unlikely that any but small quantities of sugar go through the intermediate step of lactic acid during fermentation.—J. F. B.

Sarcina [*in brewery yeast*]. Bettges and Heller. Woch. f. Brau. 1906, **23**, 69—74.

In brewery practice, sarcina often occurs in the single coccus form, and cannot be identified by the microscopic examination of yeast in the ordinary way. In order to induce the sarcina to grow in the characteristic packet form, the authors have tried the following methods:—Will's method, by cultivation in ammoniacal yeast-water, gave no growth of sarcina at all. Claussen's method, by digestion with acid ammonium fluoride, failed to separate the sarcina from the culture yeast, both being equally resistant to the antiseptic. Lindner's method, by cultivation on an object glass with exclusion of air by a vaseline ring, gave results, but only after five to eight days. The authors have devised a modification of this last method, accelerating the result by selecting a medium favourable to the sarcina and inimical to the yeast. This improved medium consists of a beer fermented in the laboratory from an unhopped wort, and attenuated as far as possible. Such beer is mixed with a barley or malt decoction, in order that free starch may be present. It is then neutralised by ammonia and an excess of ammonia equal to the quantity required to neutralise, is added, together with sufficient alcohol to bring the final alcohol content of the medium to 2—4 per cent., attention being paid to the fact that volatilisation of both alcohol and ammonia takes place during sterilisation. Vaseline is painted on the object glass to form three sides of a square, some of the yeast is mixed with the culture liquid, and a drop is carefully mounted on the glass, the fourth side of the square being closed by vaseline when the preparation is complete. Sarcina packets are generally visible after two days, but with very slight infections it may be necessary to keep the slide under observation for four days. The same medium may be employed for flask cultivations, the deposit being subjected to microscopic examination in the ordinary way, but in such cultures it is necessary to wait two or three days longer before a result is obtained. By the above method the authors have traced the nidus of a sarcina infection in their beer which, without causing the characteristic sarcina sickness, brought about an acidification and turbidity when the beer was kept for 15—18 days; the source of infection was found in places where the lacquer of the wooden fermentation tuns had worn away, and growths of sarcina had developed in the porous wood.—J. F. B.

Yeast; Production of sulphuretted hydrogen by ——. H. Will and H. Wanderscheck. Z. ges. Brauw., 1906, **29**, 73—78 and 89—96.

The authors have proved that many species of brewery yeasts, both culture yeasts and wild yeasts, are capable of producing sulphuretted hydrogen when fermenting in hopped worts. The culture yeasts are generally more active in this respect than the wild yeasts, and the evolution of sulphuretted hydrogen is generally observed towards the end of the primary fermentation. Of the culture yeasts, Frohberg yeast showed a very feeble reaction, whilst Logos yeast showed a strong one. The sources of sulphuretted hydrogen in normal worts must be either the albuminoids or the sulphates, but the exact source has not yet been ascertained. The addition of gypsum or magnesium sulphate to the wort produced no marked increase in the amount of sulphuretted hydrogen evolved, neither did the use of sulphured malt and hops cause any appreciable increase. On the other hand the addition of peptones, although they contained sulphur, actually decreased the tendency to formation of sulphuretted

The columns marked * represent original observations, the others are calculated.

The tables show that the specific gravities of the solutions of the various sugars are not identical with those of cane sugar of the same concentrations. Levulose, invert sugar and maltose solutions have higher specific gravities than the corresponding solutions of cane sugar, whilst those of dextrose have lower specific gravities. The differences at medium concentrations are not very great, and amount only to a few units in the fourth place of decimals, so that the use of the cane sugar tables for the determination of other sugars involves an error of only 0·1 per cent. and is very convenient. The comparison of the tables indicates that the hydrolysis of cane sugar to invert sugar and of maltose to dextrose is accompanied by a considerable contraction in volume.—J. F. B.

Gum; Export of —— from Senegal. Bd. of Trade J., Feb. 15, 1906.

THE total export of gum from Senegal in 1904, the last year for which statistics have appeared, was 2,370,031 kilos., valued at 44,835*l*. This was divided as follows:—Hard gum, 1,842,610 kilos., from the region north of the River Senegal, and 484,095 kilos., from the Soudan and Senegal proper; friable gum, 37,396 kilos., from all parts; dust and damaged gum, 5,930 kilos., from all parts. An export duty of 1 franc 50 centimes per kilo. was formerly levied, but was removed in May, 1905, so that there are now no royalties or export duties on gum. At least three-fourths of the gum is brought by caravans to the various posts on the River Senegal, from which they are taken to St. Louis by river transport of various kinds, and thence embarked for Europe. Since the re-opening of the Egyptian Soudan, the Senegal gum trade has been dwindling away, and is now looked upon as of quite secondary importance.

UNITED STATES PATENT.

Sugar; Method of making maize ——. F. L. Stewart, Murraysville, Pa. Assignor to S. E. Gill, Pittsburg, Pa. U.S. Pat. 811,523, Jan. 30, 1906.

THE ears are separated from the growing maize whilst they are still immature, and are at the stage of growth when the "ear is in the milk and the protruding silk is dead." The growth of the plant is then continued, when an increase of the sugar content of the stalk takes place. Finally the juice is extracted, clarified and converted into sugar or syrup.—J. F. B.

FRENCH PATENTS.

Sugar juices; Clarification of —— by means of hydrosulphurous acid or its salts. F. Schiller and K. Herbst. Fr. Pat. 358,296, Oct. 5, 1905.

HYDROSULPHUROUS acid or one of its salts, such as the

aluminium or calcium salt, is added to the crude sugar cane or beet roots during or after the extraction of the juice, whilst the latter is still in the undefecated, acid condition. The base of the hydrosulphite combines with the organic acids of the juice, precipitating them together with a considerable proportion of the albuminoids, and other non-sugar constituents. At the same time the hydrosulphurous acid, which is said to have no inverting action on the sugar, reduces the colouring matters of the juice.—J. F. B.

Starch and dextrin; Manufacture of phonograph records from ——. Comp. gen. de Phonographes, Cinematographes et Appareils de Precision. Fr. Pat. 358,366, Oct. 9, 1905.

For moulding records in the form of discs or cylinders, potato, farina or other starch, or commercial dextrin, is introduced into the mould in a dry, pulverulent condition. The mass is then subjected in the mould to a pressure of about 200 kilos. per sq. cm. During the action of this pressure the temperature of the mass is raised by means of steam to 110°—120° C. Under the combined action of heat and pressure, the starch is modified and becomes fused to a hard, horny mass, which retains the impression of the mould.—J. F. B.

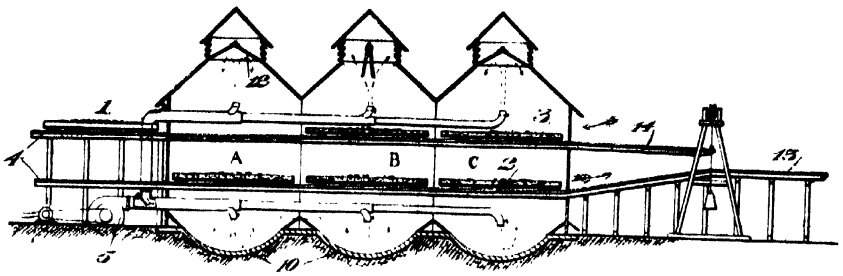
(*Continued from page* 194.)

Fermentation; Studies in ——. 1. *Chemical dynamics of alcoholic fermentation by yeast.* A. Slator. Chem. Soc. Trans. 1906, **89**, 128—142.

The author describes a new method for measuring the velocity of fermentation, over very small ranges of the reaction, by observing the increase of pressure developed in short intervals of time by the carbon dioxide evolved. A bottle of about 150 c.c. capacity is connected with a manometer by a piece of thick rubber tubing. 50 c.c. of the solution of sugar, yeast and nutrient salts are introduced into the bottle and the latter is placed in the thermostat, the apparatus is evacuated through a side tube provided on the short arm of the manometer, and the level of the mercury is read off. The change of pressure caused by the evolution of carbon dioxide is registered on the scale of the manometer, and serves as a very sensitive measure of the relative progress of the fermentation. Experiments made in this manner at 30° C. showed conclusively that when the quantity of yeast was increased, other conditions being constant, the velocity of fermentation was proportional to the concentration of the yeast. In a second series of experiments, the quantity of yeast was maintained constant whilst the concentration of the sugar (dextrose) was varied between 0·20 and 20·0 grms. per 100 c.c. It was found that, between the limits of 0·50 and 10·0 grms. of dextrose per 100 c.c., the velocity of fermentation was very nearly independent of the concentration of the sugar, a maximum point being, however, just discernible at about 5 per cent. of sugar. Below 0·5 per cent. of sugar the velocity of fermentation was influenced by the concentration of the sugar, but was never really proportional to it, whilst above 10 per cent. the excess of sugar exerted a distinct retarding influence. The above observations are most simply explained by the formation of a compound between the enzyme and the sugar by diffusion of the latter into the cell, and the velocity which is measured experimentally is the rate of decomposition of this compound. The temperature-coefficient of the reaction of fermentation is large and varies with the temperature; from the tables given in the paper, the ratios of $V_{15}°/V_{5}° = 5·6$ and $V_{40}°/V_{30}° = 1·6$ may be cited as illustrations. The temperature quotients for every 5° from 5° to 40° C. form a series of numbers which seem to be characteristic of the enzyme zymase, being independent of the concentration of yeast and dextrose, the type of yeast, the presence or absence of nutrient salts and of inhibiting agents.



The initial rates of fermentation of dextrose, levulose, sucrose and maltose are in the ratios of 1:0·92:1·05:0·9. Sucrose and maltose show constant values for the velocity of fermentation within a few minutes of the start, indicating that sufficient of the disaccharide is hydrolysed almost instantaneously for the fermentation to attain its maximum velocity. The addition of lactic acid produced no change in the velocity of fermentation, and the author concludes that it is very unlikely that any but small quantities of sugar go through the intermediate step of lactic acid during fermentation.—J. F. B.

Sarcina [*in brewery yeast*]. Bettges and Heller. Woch. f. Brau. 1906, **23**, 69—74.

In brewery practice, sarcina often occurs in the single coccus form, and cannot be identified by the microscopic examination of yeast in the ordinary way. In order to induce the sarcina to grow in the characteristic packet form, the authors have tried the following methods:—Will's method, by cultivation in ammoniacal yeast-water, gave no growth of sarcina at all. Claussen's method, by digestion with acid ammonium fluoride, failed to separate the sarcina from the culture yeast, both being equally resistant to the antiseptic. Lindner's method, by cultivation on an object glass with exclusion of air by a vaseline ring, gave results, but only after five to eight days. The authors have devised a modification of this last method, accelerating the result by selecting a medium favourable to the sarcina and inimical to the yeast. This improved medium consists of a beer fermented in the laboratory from an unhopped wort, and attenuated as far as possible. Such beer is mixed with a barley or malt decoction, in order that free starch may be present. It is then neutralised by ammonia and an excess of ammonia equal to the quantity required to neutralise, is added, together with sufficient alcohol to bring the final alcohol content of the medium to 2—4 per cent., attention being paid to the fact that volatilisation of both alcohol and ammonia takes place during sterilisation. Vaseline is painted on the object glass to form three sides of a square, some of the yeast is mixed with the culture liquid, and a drop is carefully mounted on the glass, the fourth side of the square being closed by vaseline when the preparation is complete. Sarcina packets are generally visible after two days, but with very slight infections it may be necessary to keep the slide under observation for four days. The same medium may be employed for flask cultivations, the deposit being subjected to microscopic examination in the ordinary way, but in such cultures it is necessary to wait two or three days longer before a result is obtained. By the above method the authors have traced the nidus of a sarcina infection in their beer which, without causing the characteristic sarcina sickness, brought about an acidification and turbidity when the beer was kept for 15—18 days; the source of infection was found in places where the lacquer of the wooden fermentation tuns had worn away, and growths of sarcina had developed in the porous wood.—J. F. B.

Yeast; Production of sulphuretted hydrogen by ——. H. Will and H. Wanderscheck. Z. ges. Brauw., 1906, **29**, 73—78 and 89—96.

The authors have proved that many species of brewery yeasts, both culture yeasts and wild yeasts, are capable of producing sulphuretted hydrogen when fermenting in hopped worts. The culture yeasts are generally more active in this respect than the wild yeasts, and the evolution of sulphuretted hydrogen is generally observed towards the end of the primary fermentation. Of the culture yeasts, Frohberg yeast showed a very feeble reaction, whilst Logos yeast showed a strong one. The sources of sulphuretted hydrogen in normal worts must be either the albuminoids or the sulphates, but the exact source has not yet been ascertained. The addition of gypsum or magnesium sulphate to the wort produced no marked increase in the amount of sulphuretted hydrogen evolved, neither did the use of sulphured malt and hops cause any appreciable increase. On the other hand the addition of peptones, although they contained sulphur, actually decreased the tendency to formation of sulphuretted

by the dotted arrows. The cars may be replaced by a travelling floor of gauze.—W. H. C.

Alcoholic liquors; Maturing and mixing ——. J. and T. Spencer Handsworth, and J. A. Spencer, West Bromwich. Eng. Pat. 4174, Feb. 28, 1905.

The liquor is placed in a vessel, such as a barrel, provided with a number of cross partitions arranged along its length. The partitions are perforated with a number of holes arranged so that the holes of one partition are opposite the bars of the next one. The barrel is mounted on trunnions, and is revolved or oscillated in any desired manner for a prolonged period. The liquid, occupying only a portion of the space in the barrel, is forced into intimate contact with the air. The air may be renewed periodically, and any undesirable gases may be removed by suction. In certain cases a stationary vat, provided with movable perforated partitions or blades, may be employed.—J. F. B.

Distillation and rectification [of spirits]; Combined separation of head and tail products in continuous and periodic ——. O. Pampe, Halle on the Saale, Germany. Eng. Pat. 8476, April 20, 1905. Under Int Conv, April 21, 1904.

In a rectifying or distilling column a zone exists separating the part at which the fusel oils are insoluble in the alcoholic vapours from that at which they are soluble and volatile. At this boundary zone pure water vapours are introduced, which, if they are finely divided and well distributed, lower the percentage of alcohol at that point and absorb all the fusel oil and other tail products. The vapours thus saturated with fusel oil are then conducted to the heating pipes of a portion of the apparatus called the "after-vaporiser of the head-products separator," which serves for the final separation of the head products from the pure alcohol. The abstraction of heat from the aqueous-fusel oil vapours, used in the heating pipes, dephlegmates these vapours, decomposing them into a liquid poor in fusel oil, which is returned to the still, and into vapours rich in fusel oil which are subsequently condensed. A better dephlegmation is obtained by giving these heating pipes an inclination towards the inlet, so that the movement of the vapours and the liquid which separates from them, takes place in contrary directions, and the repeated vaporisation and liquefaction causes an increase in the fusel oil contents of the vapours. Thus, the head products separator with its "after-vaporiser" forms a combined system which separates both head and tail products simultaneously.—J. F. B.

Evaporator for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, waste or spent dyes and the like, and concentrating the solids in the same; the evaporator being also applicable as a smoke washer. A. B. Lennox and T. Mackenzie. Eng. Pat. 8342, April 19, 1905. XVIIIB., see next page.

French Patent.

Wines; Process of rapidly clarifying, ageing and maturing ——. E. Monti. Fr. Pat. 358,287, Oct. 5, 1905.

The excess of oxidisable acids in the wine, *e.g.*, the malic and succinic acids, are converted into tartaric acid by cooling the wine to a temperature near its freezing point and passing a current of air through the liquid. At the same time the albuminoids of the wine are precipitated The wine is then warmed again to a temperature of 20°—30° C., in order to allow the air dissolved at the low tem perature to expand. These operations are repeatec several times in the course of about six months, and each time the wine is cooled, a further deposit of tartrates separates out. If the wine does not contain sufficient potash to fix the tartaric acid produced by oxidation, the calculated quantity of base may be added. If the action of the air be undesirable, the current of air may be replaced by one of carbon dioxide.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 195.)

(*A.*)—FOODS.

Gluten; Crude ——. F. A. Norton. J. Amer. Chem. Soc., 1906, **28**, 8—25.

The insoluble proteids of wheat obtained by kneading a dough of flour in a stream of water consist of about 75 per cent. of true gluten (gliadin and glutenin) together with small percentages of non-gluten proteids, mineral matter, fat, starch, fibre and other non-nitrogenous matter. Crude gluten represents, in addition to the true gluten content of a flour, the balance between the loss of non-gluten proteids and gain from the retention of non-nitrogenous matters. The relation of the percentage of the crude gluten to the total proteid can be thus explained by the varying composition of different flours in respect to nitrogenous and non-nitrogenous compounds. Crude gluten is a very rough expression of the gluten content of a flour or wheat, and the determination has but little worth in the valuation of flours. The relation of crude gluten to total proteid ($N \times 5{\cdot}7$) varies with the character of the flour, the percentage of crude gluten being greater than that of total proteid in bakers' and low grade flours, nearly the same in patent flours, and less in whole wheat meal. The determination of the total nitrogen and gliadin-nitrogen together with the ratio of gliadin to total proteid ($N \times 5{\cdot}7$) seems to be the best method for ascertaining the gluten content and character of the gluten in the valuation of flours.—W. P. S.

Flesh; The phosphorus content of ——. A. D. Emmett and H. S. Grindley. J. Amer. Chem. Soc., 1906, **28**, 25—63.

The authors have investigated the distribution, the quantity, and the nature of the inorganic and organic phosphorus compounds occurring in animals, the flesh of which is used as food for man. The Hart-Andrews method (this J., 1904, 33) of separating and determining the inorganic and organic phosphorus was found to give good results in aqueous extracts of flesh after the coagulable proteids had been removed. The results obtained show that there is a difference in the quantities of phosphorus present in beef and veal. Of the total phosphorus in beef, 75 per cent., and in veal, 64 per cent., is soluble in cold water, whilst of the organic phosphorus, one-fourth is soluble in the case of beef and one-sixth in that of veal. The soluble organic phosphorus in beef constitutes one-third of the total soluble phosphorus, and in

veal one-fourth. The ratio of the soluble organic to the soluble inorganic phosphorus is 3 : 5 in beef, and 3 : 9 in veal. The phosphorus forms 23·4 per cent. of the ash of beef and 20·2 per cent. of the ash of veal, whilst the soluble phosphorus compounds in beef constitute 17·8 per cent., and in veal 12·8 per cent. of the ash. The percentage of fat in the different cuts of veal has little influence on the total phosphorus content, but the cuts which are nearest the bony structure apparently contain more insoluble phosphorus than the other cuts. Different methods of cooking flesh give products which differ decidedly as to the quantities and the nature of the phosphorus contents. The soluble organic phosphorus is not in combination with the coagulated proteid, with the albumoses or with the peptones.—W. P. S.

English Patents.

Milk preparation or preserve for medicinal or nutritive purposes. L. Sarason, Berlin. Eng. Pat. 4304, March 1, 1905.

See U.S. Pat. 809,138 of 1906; this J., 1906, 132.—T.F.B.

Flour, grain, rice and other substances; Electric purifier for use in purifying ——. J. L. Lawson, Leith. Eng. Pat. 13,909, July 6, 1905.

"High tension electricity other than frictional" is used to separate bran, chaff, fibrous matter, and other impurities from flour, grain, rice, &c.

An apparatus is described consisting of insulated conducting plates charged with high tension electricity and working transversely over a tray which consists of alternate channels and spaces and has a rapid reciprocating movement. The impurities are attracted out of the channels and being deflected by the transverse movement of the plates and repelled on touching the plates, are dropped through the intermediate spaces into discharge spouts.

—R. S. H.

United States Patent.

Milk preparations; Process of making ——. S. Székely and E. Kovács, Budapest, Austria-Hungary. U.S. Pat. 811,971, Feb. 6, 1906.

See Eng. Pat. 25,624 of 1904; this J., 1905, 207.—T.F.B.

French Patent.

Milk sugar and casein; Process of extracting —— from milk. J. R. Hatmaker. Fr. Pat. 358,375, Oct. 9, 1905. Under Int. Conv., Oct. 11, 1904.

See Eng. Pat. 21,865 of 1904; this J., 1905, 1077.—T.F.B.

German Patent.

Milk; Manufacture of a substitute for skimmed —— from oil-cakes. E. Josing. Ger. Pat. 162,480, Feb. 13, 1904.

Pulverised oil-cake is treated with quicklime and extracted with lukewarm water, and after addition of sugar, the solution is separated by settling. According to one claim, instead of adding sugar, the latter is produced from the oil-cake itself by treatment with diastase.

—A. S.

(B.)—SANITATION; WATER PURIFICATION.

English Patents.

Evaporator for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, waste or spent dyes and the like, and concentrating the solids in the same; the evaporator being also applicable as a smoke washer. A. B. Lennox, Newcastle-on-Tyne, and T. Mackenzie, Glasgow. Eng. Pat. 8342, April 19, 1905.

The claim is for improvements in evaporators described in Eng. Pats. 13,227 and 18,488 of 1904 (this J., 1905, 811, 982), and consists in the provision of horizontal baffle plates, to divide the evaporator into a series of compartments. The baffle plates, which have openings on alternate sides, or alternately in the centre and at the sides, in order to impart a zigzag course to the vapour or gas, are constructed as dampers which can be withdrawn from the frames in which they slide, to enable any deposit formed on them to be removed.—W. H. C.

Dye-water and similar effluent; Apparatus for purifying ——. W. McD. Mackey, Leeds. Eng. Pat. 11,410 May 31, 1905.

The effluent is collected in a tank from which it is pumped up into a large cylindrical vessel inclined to the horizontal, the inlet pipe entering at the lowermost part of the vessel. Immediately before entering the pipe leading to the pump, the effluent receives the addition of certain chemicals, such as milk of lime, &c., which are contained in tanks situated above the collecting tank. A small pipe furnished with taps provides a regulated supply of water from the pump to the reagent tanks. The inclined vessel acts as a settling tank from which the clear effluent leaves through a pipe fixed at the uppermost angle and leading to a filter. The sediment falls towards the inlet end of the vessel and a part of it is continually stirred up by the inflowing stream, causing the freshly formed precipitate to settle more rapidly. Portions of the sediment may be withdrawn from time to time by means of a sludge cock.—W. P. S.

Sewage and other foul waters; Composition or agent for purifying —•—. J. Swallow, J. W. Swallow, and J. Filburn, Leeds. Eng. Pat. 12,092, June 9, 1905.

The composition consists of alum, 1 part; copperas (ferrous sulphate), 1 part; and Epsom salts (magnesium sulphate), 1/4 part, to which may be added chloride of lime, 1/80 part, and clay, 1 part. The first three ingredients are dissolved in water, then mixed with the others, and the whole formed into blocks of convenient size for use.—W. P. S.

Sewage; Clearing vats [settling tanks] for ——. B. Schmidt, Dresden, Germany. Eng. Pat. 24,402, Nov. 25, 1905.

A series of superposed deflecting plates are placed in front of the inlet to the tank, and extend across the width of the latter. The number of plates varies according to the velocity of the inrushing sewage; the higher the velocity, the greater the number of plates used. The plates are curved downwards, and the lower edge of each plate extends a little lower than that of the next higher one, forming between them curved sluice-ways, which break up the sewage into wide, thin bands. The velocity of the stream is thus effectively reduced, and the precipitation of the suspended matters facilitated. The clear liquid passes over the edges of troughs, provided at the top of the tank, and flows away to an exit pipe.

—W. P. S.

Sewage and other such waste products; Apparatus [settling tank] for the treatment of ——. D. Cameron and F. J. Commin, London. Eng. Pat. 27,240, Dec. 30, 1905.

A long sinuous weir is placed in the settling tank, and by being folded backwards and forwards on itself presents a great length of surface, over which the sewage trickles in a thin film. A baffle-plate is provided across the entrance to the chamber, and all sewage entering the tank has to pass under this plate. The sewage is thus rapidly freed from suspended solids, and may be delivered in a fresh condition to the filter-beds, &c. Means are provided for the removal of mud from the tank.—W. P. S.

Water; Apparatus for the [electrical] purification of ——. J. S. Zerbe, New York. Eng. Pat. 9216, May 2, 1905. Under Int. Conv., May 2, 1904.

The water enters the bottom of a vertical cylinder, the lower half of which contains a number of aluminium electrodes connected with an electric supply of low voltage. The upper part of the cylinder serves for the mixing of the water with the liberated gases. A pipe then conducts the water from the top of the cylinder to the bottom of a filter chamber. This part of the apparatus is also cylindrical in shape, and the filter is arranged axially

so that the water is forced from the space between the outer wall and the filter through the latter into the central space. A central perforated pipe reaching to the bottom of the filter chamber is provided for drawing off the water, and during the time the water is in the central space it is subjected to the further action of the gases generated in the electrical cylinder, a portion of the gases being collected for this purpose and conducted into the filter chamber.—W. P. S.

(C.)—DISINFECTANTS.

Potassium permanganate; Germicidal action of ——. J. B. Garner and W. E. King. Amer. Chem. J., 1906, **35**, 144—147.

POTASSIUM permanganate is antiseptic to *B. typhosus* in concentrations greater than N/500.—E. F. A.

UNITED STATES PATENT.

Formic aldehyde compound [*Disinfectant*]; *Process of making a* ——. A. Stephan, Gross Lichterfelde, Germany. U.S. Pat. 812,608, Feb. 13, 1906.

SEE Fr. Pat. 345,598 of 1904; this J., 1904, 1233.—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page* 195.)

ENGLISH PATENTS.

Paper; Calendering, glazing or removal of wire marks from printing ——. W. T. Haydon, London. Eng. Pat. 4414, March 3, 1905.

IN order to break up the wire marks and to give the paper a similar texture on both sides, the paper is passed between calender rolls, one (or both) of which is engraved similarly to fine linen or else has a felt or blanket of linen fabric between the metal roll and the paper. The obliteration of the wire mark by this means should be performed when the paper is slightly damp, either by artificial damping before calendering or by treating the paper before it has been fully dried on the paper machine.—J. F. B.

Cellulose or paper; Stuff purifier and screen for the manufacture of ——. L. Krause, Zell, Germany. Eng. Pat. 21,415, Oct. 21, 1905.

SEE Fr. Pat. 357,891 of 1905; this J., 1906, 132.—T. F. B.

Paper pulp; Machines for forming and combining webs of ——. H. Parker, Nashua, U.S.A. Eng. Pat. 22,718, Nov. 6, 1905. Under Int. Conv., April 17, 1905.

SEE U.S. Pat. 808,614 of 1905; this J., 1906, 88.—T. F. B.

UNITED STATES PATENTS.

Pulp treating machine. H. Parker, Nashua, N.H. Assignor to Improved Paper Machinery Co., Castine, Me. and Nashua, N.H. U.S. Pat. 811,660, Feb. 6, 1906.

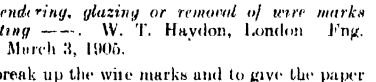
THIS invention relates to a pulp-forming cylinder rotating in a vat. The interior of the cylinder is divided by radial partitions forming compartments, to each of which suction can be applied separately, so that the pulp is first subjected to suction of low intensity and considerable volume, and subsequently to suctions of increasing intensities.—J. F. B.

Cellulose compound and process of making the same. R. W. Strehlenert, Djursholm, Sweden, and F. Reubold, Ludwigshafen. Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 812,098, Feb. 6, 1906.

SEE Fr. Pat. 347,900 of 1904; this J., 1905, 454.—T. F. B.

FRENCH PATENT.

Paper coloured on one side; Process and apparatus for making ——. Leykam-Josefsthal Act.-Ges. f. Papier- und Druck-Ind. First Addition, dated Sept. 13, 1905, to Fr. Pat. 343,186, May 16, 1904.



SEE Eng. Pat. 17,163 of 1905; this J., 1906, 87.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 197.)

Caffeine; Conversion of —— *into paraxanthine, theophylline and xanthine.* F. Fischer and F. Ach. Ber., 1906, **39**, 423—435.

CAFFEINE when subjected to the action of phosphorus pentachloride or of chlorine above 160° C., is converted into a dichlorocaffeine, containing one chlorine in the 3-methyl group, *i.e.*, 3-chloromethyl-8-chloroparaxanthine

This, on heating with water forms formaldehyde and 8-chloroparaxanthine, which is easily reduced to paraxanthine. When chlorine, dissolved in a suitable solvent, is used at about 90°—100° C. the isomeride 7′ 8-dichlorocaffeine is formed, which, on boiling with water, is converted into 8-chlorotheophylline. By the action of chlorine dissolved in phosphorus oxychloride, a tetrachlorocaffeine is formed in which all three methyl groups of caffeine have taken up chlorine. Boiling with acetic acid converts this into chloroxanthine.—E. F. A.

Bromoform; Decomposition of —— *under the influence of light and air.* N. Schoorl and L. M. Van den Berg., Pharm. Weekblad, 1906, **43**, 2—8. Chem. Centr., 1906, **1**, 441—442.

ON passing a current of air through boiling bromoform exposed to sunlight, there is formed, besides bromine and hydrobromic acid, also carbon tetrabromide, probably owing to a secondary reaction: $Br_2 + CHBr_3 = CBr_4 + HBr$. The oxidation products formed, are water, carbon monoxide, carbon dioxide, hydrobromic acid and bromine; the proportions of carbon monoxide and hydrobromic acid and of carbon dioxide and bromine differ according to the amount of oxygen used. The following equations represent the ultimate results when bromoform in sealed tubes is exposed to sunlight in the presence of a small and a large proportion of oxygen, respectively:—

$$CHBr_3 + O \rightarrow CO + Br_2 + HBr,$$
$$2CHBr_3 + 5O \rightarrow 2CO_2 + H_2O + 6Br.$$

—A. S.

Chloroform, bromoform and iodoform; Decomposition of —— *under the influence of light.* N. Schoorl and L. M. Van den Berg. Pharm. Weekblad, 1906, **43**, 8—10. Chem. Centr., 1906, **1**, 442.

IN the absence of air or oxygen, chloroform is not affected by exposure to light, but bromoform is decomposed, probably into hydrobromic acid and the hypothetical compound CBr_2. Iodoform was also partially decomposed by exposure to light, but in this case, traces of air were present. On exposure to air, in the absence of light, iodoform shows a violet colour after a quarter of an hour, whilst, after one hour, the separation of iodine is distinctly perceptible; bromoform after one hour is faintly yellow, has an acid reaction, and gives a precipitate with silver nitrate; chloroform gives no precipitate with silver nitrate even after four hours.—A. S.

Iodoform dissolved in chloroform; Decomposition of —— *by diffused daylight and by radium rays.* W. P. Jorissen and W. E. Ringer. Chem. Weekblad, 1905, **2**, 799—802. Chem. Centr., 1906, **1**, 442.

IODOFORM dissolved in chloroform appears to be completely decomposed on exposure to diffused daylight if

oxygen be present. The influence of the oxygen is shown by the fact that if a solution of iodoform in carbon bisulphide be covered with water and then exposed to diffused daylight, the decomposition proceeds only very slowly. A solution of iodoform in chloroform, solidified by means of liquid air, is apparently unaffected by exposure to bright daylight, so long as it is kept in the solid state.

By exposure to the rays from 5 mgrms. of radium bromide, 75·2 per cent. of the iodine was liberated at 25° C., from 50 c.c. of a solution of 1 grm. of iodoform in 100 grms. of chloroform, whereas under similar conditions, but without exposure to radium rays, only 18·8 per cent. of the iodine was set free.—A. S.

Arsenic; Presence of —— in so-called "pure" glycerol. J. Galimard and E. Verdier. J. Pharm. Chim., 1906, **23**, 183—184.

It is found that although the so-called "pure" glycerols of commerce fail to give any indication of arsenic by the Marsh test when introduced direct into the testing apparatus, the same samples, after being boiled for 10 hours under a reflux condenser, with an equal volume of water acidified with 1 per cent. of pure sulphuric acid, invariably give a distinct arsenical ring when so tested. It is evident, therefore, that glycerol may contain an arsenical impurity which is not reduced by the ordinary procedure of Marsh's test. Probably the arsenic is present as an ester, which requires the treatment indicated to render its presence evident. All the samples of "pure" glycerol examined as above, gave indications of arsenical contamination.—J. O. B.

Earths; Chemistry of the rare ——. G. Wyroubow and A. Verneuil. Ann. Chim. Phys., 1905, **6**, [8], 441—507. Chem. Centr., 1906. **1**, 321—324.

Electrolytic reduction; Cathodic potential and —— in sulphuric acid solution. J. Tafel. XI.A., page 222.

ENGLISH PATENTS.

Santalol esters from sandal-wood oil; Manufacture of ——. A. Knoll, M. Daege and H. Knoll (Knoll und Co.). Ludwigshafen on Rhine, Germany. Eng. Pat. 17,511, Aug. 30, 1905. Under Int. Conv., Feb. 10, 1905.

The esters of santalol with monobasic aromatic acids, and also with carbonic acid, do not possess the disagreeable taste, or exhibit the irritant effects of santalol, or of its acetyl derivative or phthalic ester. They are prepared by the ordinary methods of acidylation, *viz.*, by the action of the acid anhydrides, chlorides, or esters. The preparation of the benzoyl, salicyl and normal carbonic esters and of the ethylcarbonic esters is described in detail. —T. F. B.

Salicylic acid menthol ether; Production of ——. B. Bibus and R. Scheuble, Vienna. Eng. Pat. 8544, April 20, 1905.

Menthol is mixed with an excess of salicylic acid, and the mixture is heated for several hours at a temperature of 140°—220° C., a current of gas such as hydrogen, carbon dioxide or hydrogen chloride being passed through the mixture during the operation. The product is freed from the excess of acid by washing with a solution of an alkali carbonate, and the ether is purified by fractional distillation. The unesterified residue, consisting mainly of menthol, menthene and menthyl chloride, is converted into menthyl chloride by treatment with hydrogen chloride under pressure, and this is then converted into the salicylate by double decomposition with a metallic salicylate.—J. F. B.

Oxyhæmoglobin; Manufacture of a solution of ——. W. Jansen, The Hague, Holland. Eng. Pat. 21,172, Oct. 18, 1905.

See Fr. Pat. 358,161 of 1905; this J., 1906, 197.—T.F.B.

Dialkylmalonyl ureas; Manufacture of ——. Farbw. vorm. Meister, Lucius und Brüning, Hoechst a/Main. Germany. Eng. Pat. 26,275, Dec. 16, 1905. Under Int. Conv. Jan. 9, 1905.

Diethylmalonylthioureas are converted into dialkylmalonyl ureas by boiling them for a long time with a solution of a salt of a heavy metal, such as lead or copper, which is capable of removing the sulphur as an insoluble sulphide.—J. F. B.

UNITED STATES PATENTS.

Mercury salts of cholic acid, and process of making same. E. Wörner. Assignor to J. D. Riedel, Akt.-Ges., Berlin. U.S. Pat. 811,193, Jan. 30, 1906.

See Eng. Pat. 11,180 of 1905; this J., 1905, 930.—T.F.B.

4-Imino-2.6-dioxypyrimidine; Process of making ——. M. Conrad, Aschaffenburg, and W. Beckh, Darmstadt, Germany. U.S. Pat. 811,826, Feb. 6, 1906.

See Fr. Pat. 349,353, and Eng. Pat. 22,128 of 1904; this J., 1905, 689.—T. F. B.

Pyrimidine derivatives; Process of making ——. M. Conrad, Aschaffenburg, and W. Beckh, Darmstadt, Germany. U.S. Pats. 811,827, 811,828 and 811,829, Feb. 6, 1906.

Salicylic acid methylene acetate, and process of making same. F. W. S. Valentiner, Leipsic, Germany. U.S. Pat. 811,884, Feb. 6, 1906.

See Fr. Pat. 350,623 of 1905; this J., 1905, 750.—T.F.B.

FRENCH PATENTS.

Dialkylbarbituric acids; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. First Addition, dated Sept. 12, 1905, to Fr. Pat. 343,976, June 14, 1904. Under Int. Conv., May 12, 1905.

The present Addition to the principal patent (Ger. Pat. 162,219 of 1903; this J., 1905, 1189) relates to the preparation of dialkylbarbituric acids by heating with mineral acids the 2-thio-4-imino-5-dialkyl-6-oxypyrimidines, produced by the condensation of dialkylcyanoacetic esters with thiourea in presence of an alkali alcoholate.—T. F. B.

Unsaturated compounds; Process of transforming —— into saturated compounds. C. Dreymann. Fr. Pat. 358,212, Oct. 2, 1905. XII., page 224.

"Norgine" [Ammonium tangate from seaweed]; Preparation of —— soluble after drying, and neutral. Soc. Française la Norgine. Fr. Pat. 358,398, Oct. 10, 1905.

Tang acid, prepared from seaweed by processes previously described (see Eng. Pats. 12,275 and 12,277 of 1898; this J., 1898, 794) and containing about 35 per cent. of dry substance, is treated with a slight excess of ammonia either in the form of a concentrated solution or of gas. The ammonium tangate is then rolled into thin sheets and dried in a current of air at about 70° C., whereby the excess of ammonia is removed together with the water, and a perfectly neutral, dry product is obtained which is entirely soluble in water.—J. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 198.)

Photographic prints toned with metallic ferrocyanides; Decomposition in ——. L. Lemaire. Bull. Soc. Ind. Nord., 1905, **33**, 25.

Silver prints which have been toned with uranium ferrocyanide always exhibit deterioration after some time. Insufficient washing, and traces of hydrogen sulphide do not cause this decomposition. It is greatly retarded if the prints be washed in a dilute solution of sodium carbonate, and entirely prevented if they are then bathed in dilute nitric acid and washed. Light appears to have no detrimental effect, but exposure to the atmosphere hastens the decomposition. It would thus appear to be

due to the silver ferrocyanide formed during toning, becoming decomposed by the air; this view is confirmed by the fact that prints from which the silver ferrocyanide had been removed by means of potassium thiocyanate were perfectly stable, as were those in which the ferrocyanide was decomposed by alkali, and the resulting silver salt removed by nitric acid.—T. F. B.

ENGLISH PATENT.

Photographic developer; Manufacture of a ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 9537, May 5, 1905.

SOLUTIONS of *p*-hydroxyphenylglycinamide with alkali carbonates are energetic photographic developers The alkaline solutions are stated to be very stable. One part of the reducing agent may be dissolved in 200 parts of water with 3 parts of potassium metasulphite and 6 parts of "dry" potassium carbonate.—T. F. B.

UNITED STATES PATENTS.

XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page* 199.)

Nitroglycerin and nitrocellulose; Supposed instability of —— in presence of traces of acid. A. Leroux. Congrès de Chimie et Pharm., Liége, July, 1905. Bull. Soc. Chim. Belg., 1905, **19**, 243—244.

THE author discusses the influence of nitric and sulphuric acids on nitroglycerin and nitrocellulose explosives, and states that the supposed dangerous effect of free acid on these explosives is a fallacy, being based entirely upon assumption without any experimental evidence.—A. S.

Acids [sulphuric and nitric acids]; Fatal explosion of waste —— at Stratford. Chem. Trade J., 1906, **38**, 182—183.

THE following is a short abstract of the evidence given by Capt. Thomson, Chief Inspector of Explosives, at an inquest held with reference to the death of a man at the Abbey Mills Chemical Works, Stratford, caused by the explosion of four iron drums, each containing about 10 cwt. of waste acid (mixed nitric and sulphuric acids) from the manufacture of nitroglycerin. At the time of the explosion the deceased was loosening the bungs of the drums by means of a hammer and chisel. Capt. Thomson stated that two of the drums which exploded had jagged rents from end to end, but in the other two, the ends had been blown out and the sides forced in. The waste acid evidently contained nitroglycerin which, in the cold weather, had become frozen round the screw plug or bung. In the frozen condition, nitroglycerin was much more sensitive than when liquid, and a blow with a hammer and chisel on the bung or even a turn of the screw plug would cause an explosion. It was probable that one drum exploded first and caused another to burst in like manner, but with respect to the two drums with the ends blown out, Capt. Thomson was of the opinion that this was more a case of shock than a real explosion, and could have been caused by fluid pressure. The important question in connection with the accident was the reason for the presence of nitroglycerin in the waste acid. The acid came from the Explosives and Chem. Products Co., of Great Oakley, Essex, and at this works, as at the Government factory at Waltham Abbey, after the separation of the nitroglycerin from the waste acid by the usual method, about 2 per cent. of water was added to the acid, and until this explosion occurred, it had been thought that this water had "decomposed all after-charge of nitroglycerin." Capt. Thomson stated that an inquiry would be held by the Home Office, and he recommended that in future any waste acids supplied from a factory manufacturing nitroglycerin should be sent out in glass carboys.—A. S.

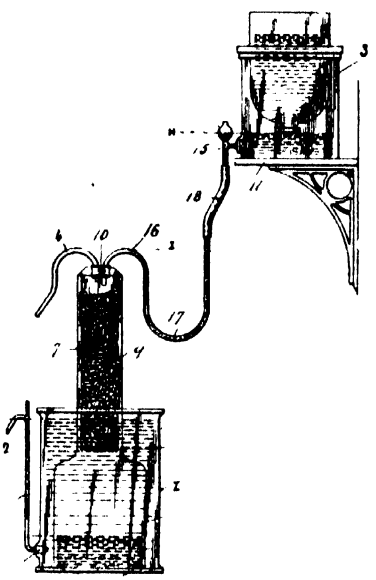
ENGLISH PATENT.

Nitroglycerine; Process of making ——. C. L. Reese, Wilmington, U.S.A. Eng. Pat. 20,310, Oct. 7, 1905.

SEE U.S. Pat. 804,817 of 1905; this J., 1906, 199.—T.F.B.

UNITED STATES PATENT.

Chlorate-powder. C. E. Mathews, Rio, Wis. U.S. Pat. 811,941, Feb. 6, 1906.



THE powder is composed of a mixture of granulated sugar (1 part) and potassium chlorate (1½ parts), together with a sufficient quantity of a liquid consisting of gasolene (1 part), spirits of turpentine (1 part), alcohol (1 part) and water (2 parts) "to moisten the mixture."—A. S.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 202.)

APPARATUS, ETC.

Gas-generator. C. L. Parsons, Durham, N.H. U.S. Pat. 811,737, Feb. 6, 1906.

THE solid, 7, from which the gas is to be generated, is contained in the vessel, 9, which is open at the bottom, is provided with a grid to support the solid, and stands in the tank, 1, which has an overflow, 2. The liquid to react upon the solid, 7, is fed from the vessel, 3, through the pipe, 15, 18, the liquid seal, 17, and the bend, 16, into the vessel, 9, at the point, 10; the gas generated escapes through 4. In the vessel, 3, a constant level, H, is maintained by a Mariotte's bottle at such a height above the level, I, in the tube, 16, that the liquid enters the vessel, 9, under a pressure equal to that in the vessel, 9, which is governed by the height of the overflow from the vessel, 1.—W. H. C.

Gas calorimeter. C. V. Boys. Roy. Soc. Proc., 1906, **77A**, 122—131.

THE author, as one of the London Gas Referees, has

designed the instrument here described, for use in determining the calorific value of gas. As compared with the Junkers and other forms of calorimeter, it offers the following advantages:—the thermometers for the water inlet and outlet are on the same level; the temperature of the outflowing water is thoroughly equalised, so that fluctuations in the thermometer readings are avoided; the instrument is easily taken to pieces and fitted up again, so that all the parts can be examined to see if they are made according to the regulations; its height is such that the thermometers can be comfortably read when the instrument stands on an ordinary table; the various water and gas connections, and condensed-water drip, can be turned round independently to any position convenient for observation; and the volume of cooling water, and hence the time required to change it, is comparatively small, thus ensuring that simultaneous readings of the inlet and outlet thermometers give the true rise of temperature.

A circular base, A, carrying the gas-pipe fitted with two No. 3 union-jet burners, B, is protected from radiation on the top by a disc of bright metal fastened beneath the three centering blocks, C. On these blocks rests a vessel, D, of sheet brass, with a central chimney of thick sheet copper, E; the drip-pipe, F, for condensation water is fixed 1 in. from the bottom; and the vessel may

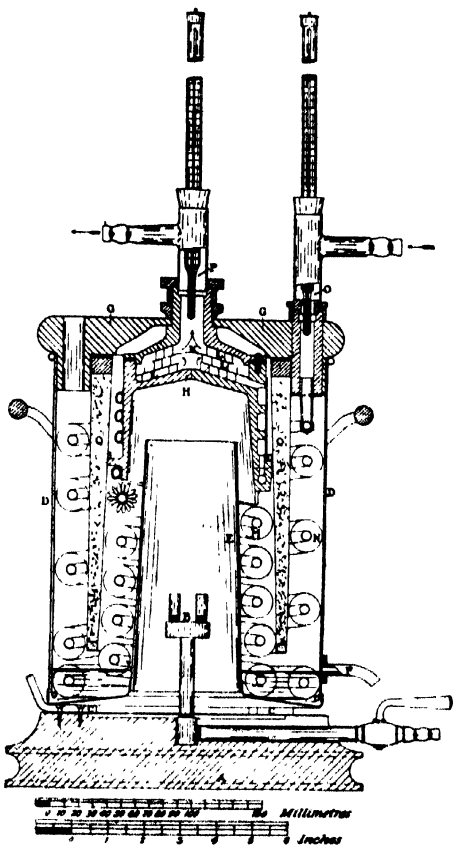


FIG 1.

be turned round to any convenient position. Attached to the lid, G, at the centre, is a brass temperature-equalising chamber for the outflowing water; two dished plates of thin brass, K, K, are held in place by three scrolls of thin brass (strips bent round like clock springs) L, L, L, a little leakage from each scroll to the one above, and from each coil to the next, being permissible, as encouraging the temperature equalisation. The pendant portion of this box is kept cool by water flowing through

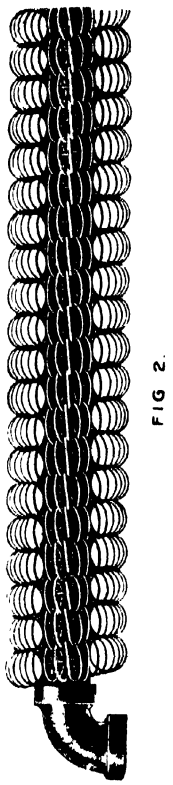

FIG 2.

a channel made in the solid metal, as shown on the right side, or formed of a tube, sweated on, as shown on the left. Connected to the water channel at the lowest point are six turns of copper pipe, M, such as is used in a motor-car radiator. The radiating surface extension may consist of coils of copper wire wound round the tube, as shown in Fig. 2, or copper strips or the like may be used. A second helix of similar pipe, N, surrounding the first, is fastened to it at the lower end and terminates at the other end in the water-inlet box, provided with the thermometer, O. The water-outlet box, P, is similar to the latter. The lowest turns of the coils, M, N, are immersed in water which, in the first instance, is put into the vessel, B. The insulating brattice, Q, between the two coils is of thin sheet brass and is filled with cork dust; it is carried by an internal flange resting on the lower edge of the casting, H. A cylindrical wall of thin sheet brass, slightly smaller than D, is secured to the lid, so that when the instrument is lifted out of the vessel, D, and placed upon the table, the coils are protected from injury; the annular space between D, and this wall, serves to prevent loss of heat to the outer air. Owing to the absence of water-cooling from all but the lower end of the chimney, E, it remains so hot that condensation does not occur upon its inner surface, and another advantage is that its extra æromotive power enables the instrument to be made much shorter than usual. To prevent corrosion by the gaseous products of combustion, the whole coil system can be lifted out when not in use, and immersed in very dilute sodium carbonate solution; and any deposit of calcium salts in the pipe system can be removed by very dilute hydrochloric acid, followed by water.—H. B.

ENGLISH PATENT.

Benzine or petroleum spirit and other liquid hydrocarbon mixtures; Instrument for testing ——. C. Roth, Frankfort-on-Maine, Germany. Eng. Pat. 21,518, Oct. 23, 1905. Under Int. Conv., Nov. 24, 1904.

THE apparatus has been devised for the purpose of determining the value of petrol or similar oils by means of their boiling points. It comprises in construction a spirit evaporator, preferably in the form of a glass tube having graduations throughout its length, or only in its lower part, or being provided in its interior with a separate scale, so that during the evaporation of the oil the diminution of its volume may be noted at any time. It is provided with a thermometer and has, in its upper part, a lateral opening for the escape of vapour. The lower part of the tube is immersed in a heating receptacle surrounded with felt and charged with lime, to which water is added by means of a dropping funnel inserted in the cover.—D. B.

INORGANIC—QUANTITATIVE.

Arseniuretted hydrogen; Reactions and methods of determining ——. H. Reckleben and G. Lockemann. Z. angew. Chem., 1906, **19**, 275—283.

ARSENIURETTED hydrogen in gaseous mixtures cannot be accurately determined by passing the gas through silver nitrate solution and afterwards weighing the separated silver. The latter persistently retains arsenic and too persistent washing causes a part of the silver to assume the colloidal form, rendering filtration impossible. Nor can the arsenious acid in the solution be conveniently titrated, owing to the fact that a portion of it is oxidised by the nitric acid, the resulting nitrous acid also interfering. Trustworthy results may, however, be obtained by shaking a measured volume of the gas with solutions of either silver nitrate, iodine in potassium iodide, iodic acid or hypochlorites, and measuring the decrease in volume. Commercial "Eau de Javelle" is the most suitable solution to use, as it absorbs arseniuretted hydrogen very rapidly. The presence of arseniuretted hydrogen in a mixture of gases may be detected by passing the latter through a small capilliary tube (so as to form minute bubbles) into an ammoniacal solution of silver nitrate. A gas containing less than 0·01 part per million of arseniuretted hydrogen gives a grey turbidity in less than two minutes. If no turbidity is produced, the absence of arseniuretted hydrogen may be regarded as proved, but, if a reaction is given, tests for the presence of stibine, hydrogen sulphide and phosphine must be made, as these substances also produce a turbidity with the silver solution.—W. P. S.

Carbon in steel; Determination of —— by direct ignition with red lead. C. M. Johnson. Proc. Eng. Soc. W. Pennsylvania, 1906, **21**, 586—602.

THE author finds that the combustion process with preliminary decomposition of the steel by potassio-cupric chloride is very untrustworthy in the case of steels containing large percentages of chromium, tungsten, or molybdenum. These steels, and indeed all steels which the author has tried, give accurate results by the direct combustion process; and, provided the temperature be kept high, drillings almost 1 mm. thick can be completely burnt. A porcelain boat is used, and the mixture of drillings and red lead is covered with a lid of asbestos, to prevent "creeping." The general arrangements are as usual, save that the carbon dioxide is absorbed in baryta water, and the barium carbonate formed weighed.—J. T. D.

ORGANIC—QUANTITATIVE.

Mercury and iodine; Determination of —— in antiseptic soaps. A. Seidell. J. Amer. Chem. Soc., 1906, **28**, 73—76.

A WEIGHED quantity of the soap is treated in an Erlenmeyer flask with about 150 c.c. of 95 per cent. alcohol, and from 3 to 5 c.c. of concentrated hydrochloric acid. The mixture is warmed and successive small quantities of water added until a perfectly clear solution is obtained on shaking. If suspended particles of impurities be present, the solution must, of course, be filtered. A slow current of hydrogen sulphide is then passed through the solution for about one hour. The precipitated mercury sulphide is collected on a filter and washed with 95 per cent. alcohol. The weight of mercury sulphide obtained multiplied by 1·955 gives the amount of mercuric iodide in the portion of the sample taken. The filtrate from the mercury sulphide may be evaporated on the water-bath to about one-third the original volume, water added to replace the alcohol, and the solution filtered after cooling, to remove the separated fats. The iodine is then liberated with nitrous acid, shaken out with chloroform and titrated as usual.—W. P. S.

Dextrose; Determination of ——. B. Glassmann. Ber. 1906, **39**, 503—508.

THE determination of dextrose by the reduction of alkaline solutions of mercuric salts may be carried out either with the Liebig-Knapp alkaline mercuric cyanide solution, or with Sachse's alkaline mercuric-potassium iodide solution. The former is made by dissolving 10 grms. of mercuric cyanide in water, adding 100 c.c. of caustic soda lye of 1·145 sp. gr. and diluting to 1 litre. Sachse's solution consists of 1·8 grms. of mercuric iodide and 2·5 grms. of potassium iodide dissolved in a little water, with the subsequent addition of 8 grms. of caustic potash, and dilution to 100 c.c. The reaction proceeds quantitatively in both cases in strictly stochiometrical ratios of 1 mol. of dextrose to three atoms of mercury. The dextrose solution is added to an excess of the boiling solution of mercury salt, the reduced mercury is filtered off, and dissolved in a sufficient quantity of hot concentrated nitric acid. The mercury in this solution is titrated with N/100 ammonium thiocyanate solution by Volhard's method. A gasometric method is also described, based on the decomposition of hydrazine sulphate by mercuric salts with evolution of nitrogen in the ratio N_2 : 2Hg. For this purpose the dextrose solution is boiled with a known quantity of mercuric solution previously standardised gasometrically by hydrazine sulphate. The excess of mercuric salt remaining unreduced is then determined in the same manner. A Hempel's gas evolution flask is employed. The results, according to determinations cited in the paper, agree well in both methods with the quantities of dextrose actually employed.—J. F. B.

Malt analysis committee; Report of the —— to the Council of the Institute of Brewing. L. Briant, A. J. Brown, A. C. Chapman, J. Heron, A. R. Ling, E. R. Moritz, A. Gordon Salamon, and L. T. Thorne. J. Inst. Brewing, 1906, **12**, 1—10.

ON April 7th, 1905, the Council appointed the above-mentioned chemists for the purpose of reporting methods for determining the extract, moisture, diastatic power, colour and percentage of ready-formed sugars in malt; and requested them to invite the opinions and views of other representative chemists upon the suggested methods.

Commercial methods of malt analysis.—The Seck mill, set at 25, is to be used throughout. In order to allow for loss in the mill, a quantity of malt, slightly in excess of that required for each determination, is to be separately weighed out and ground. Finally, the exact amounts of grist, subsequently required for the various determinations, are weighed out. It is not permissible to grind at the outset sufficient malt for all the determinations, and to weigh out the various quantities from this grist.

Extract and tint.—Extract.—Fifty grms. of ground malt are to be weighed out and mashed in a copper or glass beaker of about 500 c.c. capacity with 360 c.c. of distilled water previously heated to 154°—155° F. The beaker is covered with a clock glass, and placed in a water-bath, so that its contents are kept at 150° F. for 55 minutes. The mash is stirred at intervals of about ten minutes during this time. The temperature is then raised to 158° F. in five minutes, and the whole mash washed into a flask graduated to 515 c.c., cooled to 60° F., made up to the mark with distilled water at the same temperature, well shaken, and filtered through a large ribbed paper. The specific gravity of the filtrate is then determined at

once at 60° F., compared with water at the same temperature. The excess specific gravity over water (=1000) multiplied by 3·36 gives the extract in brewers' lb. per standard quarter of malt.

If preferred, the mashing can be carried out directly in the 515 c.c. measuring flask. In this case the mash should be shaken at intervals of about 10 minutes.

Tint.—For this determination the Lovibond tintometer is to be employed. The above wort, filtered perfectly bright, is to be placed at once in a 1 in. cell, and its tint recorded in colour units of the series "52" glasses. The experiment should not be carried out in direct sunlight, and the light must fall equally on both halves of the white plate, so that both fields—*viz.*, the malt extract field and the standard field are equally illuminated. To test this, the glasses and the cell should be reversed, and all results rejected when the figures do not agree, whichever side the cell is placed.

Moisture.—About 5 grms. of ground malt are to be accurately weighed out in a small shallow vessel, about 2 ins. in diameter and 1 in. in depth, heated for five hours in a boiling-water oven, allowed to cool in a desiccator, and re-weighed, the loss in weight being taken as the moisture content and calculated as a percentage on the malt.

Diastatic Activity (Lintner value).—Twenty-five grms. of ground malt are to be extracted with 500 c.c. of distilled water (*see* Appendix) for three hours at 70° F., and filtered bright, stirring well every half-hour. A portion of the filtrate (3 c.c.) is allowed to act on 100 c.c. of a 2 per cent solution of soluble starch (*see* Appendix) at 70° F. for an hour in a 200 c.c. flask. N/10 caustic alkali (10 c.c.) is then added in order to stop further diastatic action. The liquid cooled to 60° F., made up to 200 c.c. with distilled water at the same temperature, well shaken, and titrated against 5 c.c. portions of Fehling's solution, using ferrous thiocyanate as indicator.

The titration is carried out as follows:—

Five c.c. of Fehling's solution (*see* Appendix) are accurately measured into a 150 c.c. boiling flask, and raised to boiling over a small naked Bunsen flame. The converted starch solution is added from a burette, in small quantities, at first of about 5 c.c., the mixture being kept rotated and boiled after each addition until reduction of the copper is complete, which is ascertained by rapidly withdrawing a drop of the liquid by a glass rod, and bringing it at once in contact with a drop of the indicator on a porcelain or opal glass slab.

The preparation of Fehling's solution and of the indicator are dealt with in the Appendix.

The results are calculated by the following formula:—

$$A = \frac{1000}{XY},$$

in which A equals the diastatic activity, X equals the number of cubic centimetres of malt extract contained in 100 cc., of the fully diluted starch conversion liquid, and Y equals the number of cubic centimetres of the same liquid required for the reduction of 5 c.c. of Fehling's solution.

The above method (using 3 c.c. of malt extract to 100 c.c. of 2 per cent. soluble starch solution) is not accurate for malts having a diastatic capacity exceeding 50 Lintner; in the case of such malts the relative volume of malt extract must be less, say 2 c.c., or, for malts of the highest diastatic capacity, such as are frequently used by distillers and vinegar makers (*i.e.*, malts of over 80 Lintner), an even smaller volume of extract must be taken.

Cold water extract per cent.—Twenty-five grms. of ground malt are to be digested with 250 c.c. of distilled water containing 20 c.c. of N/10 ammonia (*i.e.* 20 c.c. of N/10 ammonia made up to 250 c.c. with distilled water) for three hours at 70° F., stirring about three or four times during this period. After filtering, the specific gravity of the bright filtrate is taken at 60° F., compared with water at the same temperature. The excess specific gravity over water (=1000) divided by 3·86 and multiplied by 10 gives the cold water extract per cent.

The percentage of ready-formed soluble carbohydrates may be approximately arrived at by subtracting 4 from the value obtained for the cold water extract per cent.

Statements of results.—The results, expressed to the nearest first decimal place only, except in the case of diastatic activity, which should be recorded only to the nearest integer, are to be stated according to the following scheme:—

Extract per standard quarter, brewers' lb.
Moisture, per cent.
Diastatic activity (Lintner value).
Tint (10 per cent. wort, 1 in. cell, "52" series Lovibond).
Cold water extract, per cent.
Equivalent approximately to ready-formed soluble carbohydrates.

Appendix.

Preparation of soluble starch.—Purified potato starch is to be digested with dilute hydrochloric acid of sp. gr. 1037·0, at the room temperature (60°—65° F.) for seven days, stirring the mixture daily. The operation is conveniently carried out in Winchester quart bottles, 1 lb. of starch and 1000 c.c. of diluted acid being suitable quantities for each such bottle. It is washed very thoroughly by decantation, at first with tap water, and later on with distilled water, until the wash water is free from chloride. It is collected on a filter paper placed in a Buchner's funnel, pumped as dry as possible, and then spread out on a new unglazed porous plate. The starch should be dried at a gentle heat (110° F.) as quickly as possible. When dry, the starch is triturated in a porcelain mortar and rubbed through a fine hair sieve.

Starch solution.—In determining diastatic capacity, the starch must be dissolved in boiling water at the rate of 2 grms. of the starch per 100 c.c. of water; the solution is then cooled to 70° F. for use. It should be perfectly mobile (not gelatinous) indicating perfect conversion into soluble starch, and show only a negligible reducing action on Fehling's solution; and it should be neutral to litmus solution.

The water used in making up the starch solution must be pure. Commercial distilled water frequently contains ammonia, nitrous acid, and other impurities, which appreciably influence diastatic conversion, and, therefore, the result. The water should be redistilled with addition of a little potassium permanganate and soda (the solution used in water analysis will do), in a glass apparatus provided with a trap, until the distillate is pure and neutral to litmus solution.

Preparation of Fehling's solution.—(A) *Copper solution.* Recrystallised copper sulphate (69·2 grms.) is to be dissolved in water and the solution made up to 1 litre at 60° F. with distilled water.

(B) *Alkaline tartrate solution.*—Rochelle salt (346 grms.) and caustic soda (150 grms.) are to be dissolved in about 600 c.c. of distilled water, the solution cooled and made up to 1 litre at 60° F. with distilled water.

The two solutions are to be kept separate, and equal volumes mixed for each day's work, from which mixture the volumes specified in the analytical methods are measured out at 60° F.

Preparation of the indicator.—One grm. of ferrous ammonium sulphate and the same quantity of ammonium thiocyanate are dissolved in 10 c.c. of water at a moderate temperature, say at 120° F., and immediately cooled; 5 c.c. of concentrated hydrochloric acid are then added. The solution so obtained has invariably a brownish-red colour, due to the presence of ferric salt, which latter must be reduced. For this purpose zinc dust is the most satisfactory reagent to employ, and a mere trace is sufficient to decolorise the solution if pure reagents have been employed.

When kept for some hours, the indicator develops the red coloration by atmospheric oxidation. It may, however, be decolorised by the addition of a further quantity of zinc dust, but its delicacy is decreased after it has been decolorised several times. For practical purposes the indicator may be too delicate, and it is recommended to prepare it the day before it is required for use, as it gives the best results after the second decolorisation.

Recommendations as to sampling.—It is obvious that samples sent for analysis should, so far as possible, be fairly representative of bulks, and this requires the

more care when the bulks (whether from maltings or deliveries) are large, and when the malt contains any appreciable number of hard corns, and further, when there is any marked irregularity in curing.

In the case of deliveries, samples should be drawn from at least 10 sacks if the consignment amounts to over 100 sacks, or if the parcel be smaller, then from 10 per cent. of the number of sacks. The sample should be withdrawn, not from the surface of a sack, but from a depth at least as far from the surface as the hand will reach when buried up to the wrist.

These bulk samples should be put into a large tin kept for the purpose, and well shaken; a smaller tin (of at least a pint capacity) is then filled from the larger one, and sent to the analyst, the remainder being reserved in other similar tins if the analysis is to be checked. The lids of all tins containing samples for analysis should fit well, and it is desirable as an additional safeguard in those cases in which special airtight tins are not employed to affix gummed paper round the junction of the lid and tin. Malts are really better sent in clean, carefully dried, stoppered bottles. Stoppered beer bottles answer the purpose.

In sending malts from heaps, surface samples should be avoided as in the case of sacks, and three to six samples should be withdrawn and mixed in a large tin, a small tin or bottle being filled with a portion of the mixture and sent for analysis. When the malt lies in bins a sample from the spout will generally fairly represent the bulk if the bin has been drawn upon. If not, the bin should be probed at different depths, five or six samples withdrawn, mixed in a large tin, and a small tin or bottle filled from the mixture and sent for analysis.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 207.)

National Chemical Laboratory (Chemische Reichsanstalt) for Germany.

The Council of the German Chemical Society purposes petitioning the Government to grant the establishment of a National Chemical Laboratory on the lines of the "Physikalische Reichsanstalt." The work of the Laboratory is to include (i.) the International Atomic Weights Commission; (ii.) the International Commission on Analysis; (iii.) the International Commission for the Analysis of Artificial Manures and Foodstuffs (Animals). In favour of its proposal special attention is directed by the Council to the example of Great Britain, which, by its Alkali Act (1863) has not only conferred benefits upon the manufacturer, but has also largely contributed to the purification both of the air and of the water courses. By this and other movements, it is pointed out, Great Britain has during last century accentuated the importance of the relations of chemical science to industry.

Trade Report.

Canals and Waterways; Royal Commission on ——.

The King has been pleased to appoint a Royal Commission to inquire into the canals and inland navigations of the United Kingdom and to report on—

(1) Their present condition and financial position.

(2) The causes which have operated to prevent the carrying out of improvements by private enterprise, and whether such causes are removable by legislation.

(3) Facilities, improvements, and extensions desirable in order to complete a system of through communication by water between centres of commercial, industrial, or agricultural importance, and between such centres and the sea.

(4) The prospect of benefit to the trade of the country compatible with a reasonable return on the probable cost.

(5) The expediency of canals being made or acquired by public bodies or trusts and the methods by which and what should be the system of control and management of such bodies or trusts.

The following are the Royal Commissioners:—The Right Hon. Lord Shuttleworth (Chairman), Lord Kenyon, Lord Brassey, K.C.B., Lord Farrer, the Right Hon. Sir John Dorington, Sir John Brunner, M.P., Sir Francis Hopwood, K.C.B., C.M.G. (Permanent Secretary to the Board of Trade), W. J. Crossley, Esq., M.P., Russell Rea, Esq., M.P., J. F. Remnant, Esq., M.P., P. Snowdon, Esq., M.P., Henry Vivian, Esq., M.P., L. A. Waldron, Esq., M.P., R. C. H. Davison, Esq., C.E., J. P. Griffith, Esq., C.E., Dr. A. J. Herbertson, J. C. Inglis, Esq., C.E., H. F. Killick, Esq., John Wilson, Esq.

W. B. Duffield, Esq., M.A., barrister-at-law, will act as secretary.

New Books.

Metropolitan Water Board. Reports on the Results of the Chemical and Bacteriological Examination of the London Waters, for the Month ending November 30, 1905 (No. 1), and December, 1905 (No. 2). By Dr. Houston, Director of Water Examinations, Metropolitan Water Board. Price 2s. 6d. nett.

Report No. 1 is printed *in extenso*, as being the first issued, filling 87 pages and containing 9 maps. It is shown that in all during the month of November, 285 samples have been taken and analysed, and 699 have been examined bacteriologically. The Report (No. 2) for December is considerably summarised, and only occupies 8 pages. There have been examined chemically, 247 samples, and bacteriologically, 600 samples during this month.

Chemistry of the Proteids. By Gustav Mann, M.D., B.Sc., University Demonstrator of Physiology, Oxford. Based on Prof. Otto Cohnheim's "Chemie der Eiweisskörper." Macmillan and Co., Ltd., London. The Macmillan Company, New York. 1906. Price 15s. nett.

8vo volume, containing 584 pages of subject matter, with an alphabetical index. The subject matter is subdivided as follows:—I. Reactions of Albuminous Substances. II. Dissociation Products. III. Synthesis of Albumins. IV. Constitution of Albumins. V. Albumoses and Peptones. VI. Salts of Albumins. VII. Halogen-Albumins and Allied Matter. VIII. Physical Properties of Albumins. IX. Classification of Albumins. X. The Albumins Proper. XI. The Proteids. XII. The Albuminoids.

Mineral Resources of the United States. Department of the Interior, United States Geological Survey. Calendar Year, 1904. David Day, Chief of Division of Mining and Mineral Resources. Government Printing Office. Washington. 1905.

8vo volume, containing 1234 pages of subject matter, and an alphabetical index. The text deals with the following subjects:—I. Iron Ores. II. Statistics of the American Iron Trade for 1904. III. Manganese Ores. IV. Gold and Silver. V. Copper. VI. Lead. VII. Zinc. VIII. Aluminium and Bauxite. IX. Mercury. X. Steel and Iron-hardening Metals. XI. Nickel and Cobalt. XII. Chromium. XIII. Tungsten. XIV. Molybdenum. XV. Vanadium and Uranium. XVI. Titanium. XVII. Manganese. XVIII. Platinum. XIX. Lithium Minerals. XX. Antimony. XXI. Arsenic. XXII. Bismuth. XXIII. Tin. XXIV. Coal. XXV. Coke. XXVI. Gas, Coke, Tar, and Ammonia at Gas Works, and in Retort Coke Ovens. XXVII. Petroleum. XXVIII. Natural Gas. XXIX. Asphaltum and Bituminous Rock. XXX. Stone. XXXI. Clay-Working Industries. XXXII. Cement. XXXIII. Precious Stones. XXXIV. Talc and Soapstone. XXXV. Abrasive Materials. XXXVI. Borax. XXXVII. Bromine. XXXVIII. Fluorspar and Cryolite. XXXIX. Gypsum and Gypsum Products. XL. Phosphate Rock. XLI. Salt. XLII. Sulphur and Pyrites. XLIII. Barytes. XLIV. Mineral Paints. XLV. Fuller's Earth. XLVI. Asbestos. XLVII. Flint and Felspar. XLVIII. Glass-Sand and Other Sand. XLIX. Graphite. L. Magnesite. LI. Mica. LII. Mineral Waters.

Official Notices.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. Full particulars will be announced later.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

LONDON SECTION.

The next meeting of the London Section will be held at the Chemical Society's Rooms, Burlington House, Piccadilly, on Monday, April 2nd, when the following papers will be read:—"The Ropiness in Flour and Bread, and its detection and prevention," by E. J. Watkins; "The Rösе-Herzfeld and Sulphuric Acid Methods for determinining the Higher Alcohols," by V. H. Veley, F.R.S.

List of Members Elected.

March 23rd, 1906.

Bowers, H. L., 50, Colborne Street, Toronto, Ont., Canada, Consulting Chemist and Metallurgist.

Burrough, Ernest Jas., Cale Street Distillery, Chelsea S.W., Rectifier.

Compton, Miss N. J., Library, University of Nebraska Lincoln, Neb., U.S.A., Librarian.

Fernyhough, F., The Abbey Cottage, Leek, Staffs., Print Works Manager.

Goodall, Wm. Leslie, Finboro' Road, Stowmarket, Suffolk, Works Chemist.

Goodhue, Leonard H., c/o Boston Rubber Shoe Co., Melrose, Mass., U.S.A., Chemist.

Harris, Wm. G., jun., 25, William Street, Toronto, Ont., Canada, Metallurgist.

Hibbert, John C., 6, Victoria Road, West Bridgford, Nottingham, Chemist.

Howe, Chester A., 124, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.

Lee, William, 43, Daisy Bank, Heaton Park, Manchester, Works Chemist.

Levinstein, Edgar, 74, India Street, Boston, Mass., U.S.A., Chemical Manufacturer.

Lyon, Geo. A., Lowell Machine Shop, Lowell, Mass., U.S.A., Selling Agent.

McDowall, William, Oficina Santa Luisa, Taltal, Chile, South America, Analytical Chemist.

Mawson, Fred. E., 135, Pearl Street, Boston, Mass., U.S.A., Dyestuff Merchant.

Olmsted, Fred. A., American Writing Paper Co., Holyoke, Mass., U.S.A., Chemical Engineer.

Palm, Otto G., 41, Colborne Street, Toronto, Canada, President (Atteaux Dye. and Chemical Co.).

Pennymore, Percy G., Eskbank Iron and Steel Works, Lithgow, New South Wales, Chemist and Blast Furnace Manager.

Peterson, Chas. A., 106, Front Street East, Toronto, Canada, Chemist.

Reid, James, Moffat Mills, Airdrie, N.B., Chemist.

Reinhold, Gustave C., 11, Hervey Road, Blackheath, S.E., Works Manager.

Stebbins, Chas. H., 113, Malvern Street, Melrose, Mass., U.S.A., Assistant Chemist, Boston Navy Yard.

Tillson, Henry E., 12, Derby Street, Concord Junction, Mass., U.S.A., Dyer.

Trotz, Johan O. E., 311, Main Street, Worcester, Mass., U.S.A., Consulting Engineer.

Walker, Jas. W., Stonydale, Oakamoor, Stoke-on-Trent, Assayer.

White, Wm. T., c/o American Hide and Leather Co., Lowell, Mass., U.S.A., Leather Manufacturer.

Wiffen, Henry J., 17, Albany Road, Manor Park, Essex, Manufacturing Chemist.

Wikner, Sigurd A., Hull Road, Hedon near Hull, Tar Works Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the journal depends.]

Baer, Dr. S. H., l/o New York; 212, South 7th Street, St. Louis, Mo., U.S.A.

Bain, J. Watson, l/o Charles Street; School of Practical Science, Toronto, Canada.

Bernays, Jos., l/o Newgate Street; Blenheim Club, St. James Square, London, S.W.

Brooks, H. Kibbe, l/o Swanton, Vt.; Claremont, N.H., U.S.A.

Brown, Walter B., l/o Chicago Heights; 89, Board of Trade Building, Chicago, Ill., U.S.A.

Buchanan, E. F., l/o Nürnbergerstr.; Eisenacherstrasse, 10[II], Berlin, W.

Burford, S. F., l/o Kirby Muxloe; Beechworth, Stoneygate Road, Leicester.

Burkhardt, Dr. G. A.; all communications to Pragerstrasse, 12, Berlin W. 50, Germany.

Davidson, Alex., jun., l/o Glasgow; 8, Traquair Park, Corstorphine, Midlothian, N.B.

Emery, Arthur L., l/o Crossley Building, 83-85, New Montgomery Street, San Francisco, Cal., U.S.A.

Greville, H. Leicester, l/o Catford; 39, Croft Road, Bromley, Kent.

Harrington, Dr. B. J.; Journals to University Library, McGill University, Montreal; and communications 295, University Street, Montreal, Canada.

Harrison, W. H.; all communications to Knostrop Sewage Works, Leeds.

Highley, A., l/o Horsforth; 26, Parkfield Avenue, Bradford Moor, Bradford, Yorks.

Hill, Sydney; all communications to Eastholme, Princes' Avenue, Hull.

Howard, Tom, l/o Isleworth; (communications) Floral Villa, Lampton Road, Hounslow, and (Journals) c/o Williams Bros. and Co., Hounslow, W.

Jackson, Samuel, l/o Madras; Edzell Park Avenue, Knaresborough, Yorks.

Joplin, G. C.; Journals to 12, Harrington Street, Sydney, N.S.W., Australia.

Journand, Louis, l/o Bourg de Péage; Epaillage Chimique, Pont Evêque, près Vienne (Isère), France.

Langmuir, F. L., l/o Freiburg; Herold's Institute, Drummond Road, Bermondsey, S.E.

Major, Ernest, l/o Balmain, P.O.; Eagle Paint Works, Snails Bay, Balmain, Sydney, N.S.W.

O'Shea, Prof. L. T.; all communications to Dept. of Applied Science, St. George's Square, Sheffield; Prof. of Applied Chemistry, University of Sheffield.

Pedler, Sir Alex., F.R.S., l/o Calcutta; retain journals.

Pizey, J. H., l/o Glasgow; Bella Vista 19, Minas de Rio Tinto, Prov. de Huelva, Spain.

Pope, Prof. W. J., F.R.S., l/o Higher Broughton; Corchester, Bramhall, Cheshire,

Pratt, Walter E., l/o East Road; "Patchetts," Caton, near Lancaster.

Prentice, Jas.; Journals to 5, Ashgrove Terrace, Partickhill, Glasgow.

Rodwood, Iltyd J., l/o Belvedere; The Chestnuts, Erith Road, Bexley Heath, Kent.

Rüger, Richard, l/o Ash Leigh; 8, Alroy Road, Anfield, Liverpool.

Schaffer, H. A., l/o Spring Garden Street; 301, Burke Street, Easton, Pa., U.S.A.

Scrymgeour, W., l/o Southern Cross; Lewiss Street, Lamington Heights, Kalgoorlie, West Australia.

Smith, R. F. Wood, l/o Bartholomew Close; 9, Lower Thames Street, London, E.C.

Teeple, Dr. J. E., l/o Easton; Industrial Laboratories, 164, Front Street, New York City, U.S.A.

Ward, Dudley R.; all communications to Mysore Gold Mine, Marikuppam, Mysore State, S. India.

Worstall, R. A., l/o Chicago; 522, Church Street, Evanston, Ill., U.S.A.

Change of Address Required.

Davies, W. Rhys, l/o 60, Northampton Terrace, Bradford.

Deaths.

Claudet, Francis G., Ennismore, Willesden Lane, London, N.W. March 13.

JOURNAL OF THE

Society of Chemical Industry.

No. 6.—Vol. XXV. SUPPLEMENT. March 31, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Dr. Edward Divers, F.R.S.
GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

OFFICES:—
Telegraphic Address: "59 *Palatable, London.*" 59, Palace Chambers, Westminster, S.W. *Telephone No.:* "715, *Victoria.*"

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. Full particulars will be announced later.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

LONDON SECTION.

The next meeting of the London Section will be held at the Chemical Society's Rooms, Burlington House, Piccadilly, on Monday, April 2nd, when the following papers will be read:—"The Ropiness in Flour and Bread, and its detection and prevention," by E. J. Watkins; "The Rösе-Herzfeld and Sulphuric Acid Methods for determinining the Higher Alcohols," by V. H. Veley, F.R.S.

List of Members Elected.

March 23rd, 1906.

Bowers, H. L., 50, Colborne Street, Toronto, Ont., Canada, Consulting Chemist and Metallurgist.

Burrough, Ernest Jas., Cale Street Distillery, Chelsea S.W., Rectifier.

Compton, Miss N. J., Library, University of Nebraska Lincoln, Neb., U.S.A., Librarian.

Fernyhough, F., The Abbey Cottage, Leek, Staffs., Print Works Manager.

Goodall, Wm. Leslie, Finboro' Road, Stowmarket, Suffolk, Works Chemist.

Goodhue, Leonard H., c/o Boston Rubber Shoe Co., Melrose, Mass., U.S.A., Chemist.

Harris, Wm. G., jun., 25, William Street, Toronto, Ont., Canada, Metallurgist.

Hibbert, John C., 6, Victoria Road, West Bridgford, Nottingham, Chemist.

Howe, Chester A., 124, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.

Lee, William, 43, Daisy Bank, Heaton Park, Manchester, Works Chemist.

Levinstein, Edgar, 74, India Street, Boston, Mass., U.S.A., Chemical Manufacturer.

Lyon, Geo. A., Lowell Machine Shop, Lowell, Mass., U.S.A., Selling Agent.

McDowall, William, Oficina Santa Luisa, Taltal, Chile, South America, Analytical Chemist.

Mawson, Fred. E., 135, Pearl Street, Boston, Mass., U.S.A., Dyestuff Merchant.

Olmsted, Fred. A., American Writing Paper Co., Holyoke, Mass., U.S.A., Chemical Engineer.

[C.S.] 26,178 (1904). Vogt. Apparatus for producing combustion gases under pressure. March 7.

„ 26,556 (1905). Campbell, Binnie and Reid (Smith). *See under* X.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 5435. Marriott. Impts. in pitch in its application to artificial fuel making as a waterproof agglomerant and preservative.* March 6.

„ 5872. Brown. Treating paraffin wax. March 10.

[C.S.] 7699 (1905). Van der Ploeg. Manufacture of emulsions of heavy mineral oils or the like. March 21.

„ 17,464 (1905). Johnson (Deutsche Continental Gas.-Ges.). *See under* II.

„ 18,174 (1905). Ziegler. Kiln for distilling peat. March 14.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 4687. Imray (Soc. Chem. Industry in Basle). Manufacture of a red vat dyeing dyestuff.* Feb. 26.

„ 5244. Ransford (Cassella und Co.). Manufacture of disazo dyestuffs. March 3.

„ 5245. Ransford (Cassella und Co.). Manufacture of polyazo dyestuffs. March 3.

„ 5749. Newton (Bayer und Co.). Production of new azo dyestuffs and intermediate products. March 9.

„ 5890. Newton (Bayer und Co.). Manufacture of a new dyestuff of the anthracene series. March 10.

„ 5959. Newton (Bayer und Co.). Manufacture of dyestuffs of the anthracene series. March 12.

„ 6189. Lake (Chem. Fabr. Griesheim-Elektron). Manufacture of azo-colouring matter.* March 14.

„ 6198. Lake (Chem.-Fabr. Griesheim-Elektron). Manufacture of blue sulphurised dyestuffs.* March 14.

[C.S.] 14,578 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of new compounds and colouring matters of the anthracene series. March 14.

„ 14,787 (1905). Ransford (Cassella und Co.). Manufacture of trisazo dyestuffs. March 21.

„ 16,227 (1905). Imray (Meister, Lucius und Brüning). Manufacture of blue colouring matters of the quinoline group and photographic surfaces sensitised therewith. March 21.

„ 16,632 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of derivatives of methylanthraquinone. March 21.

„ 18,176 (1905). Cooper (Bayer und Co.). Manufacture of anthracene dyestuffs. March 14.

„ 23,034 (1905). Kalle and Kalle. Manufacture of *o*-oxymonoazo dyes of the naphthalene series. March 21.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 4728. Hey and Smith. Discharging or removing dye from wool, silk and other fibres, and bleaching, carbonising or sterilising such fibres. Feb. 27.

„ 4981. Rhodes. Apparatus for preparing, dyeing, scouring, ageing, settling, bleaching, or otherwise treating with liquids, pieces, warps, or other fibrous material. March 1.

[A.] 5246. Ransford (Cassella und Co.). Production of easily dischargeable claret shades on cotton goods. March 3.

„ 5613. Horridge and Cornall. Printing and dyeing textile fabrics.* March 8.

„ 5836. Bailey. Machines for washing or scouring textile piece goods. March 10.

„ 5845. Whiteley. Machines for drying, shrinking or ageing textile fabrics. March 10.

„ 6072. Friedrich. Manufacture of silk-like threads and cellulose solutions therefor. [Belg. Appl., March 13, 1905.]* March 13.

„ 6166. Gorrand. Manufacture of fireproof artificial silk.* March 14.

„ 6207. Ingham. Manufacture of waterproof fabrics. March 14.

[C.S.] 4755 (1905). Linkmeyer. Manufacture of artificial threads. March 14.

„ 4765 (1905). Linkmeyer. Manufacture of lustrous cellulose threads. March 14.

„ 4779 (1905). Tatterson. Wool-washing machines. March 14.

„ 5296 (1905). Zeitschner. Process of bleaching textile fibres, yarns and fabrics. March 21.

„ 9809 (1905). Frankenstein, Spencer, Spencer and Lyst. Printing calico and similar fabrics. March 14.

„ 13,053 (1905). Ainley. Machines for washing and scouring textile fabrics. March 21.

„ 15,524 (1905). Johnson (Badische Anilin und Soda Fabrik). Discharging dyed materials and pastes to be employed therein. March 7.

„ 17,026 (1905). Jones. Wool-scouring machines. March 7.

„ 21,125 (1905). Boult (Bond). Manufacture of waterproof fabrics. March 14.

„ 23,911 (1905). Lohmann. Method of filling the pores or interstices of woven fabric with pulverised substance. March 21.

„ 26,381 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of pastes for the discharge of dyed textile fabrics. March 7.

VI.—COLOURING WOOD, LEATHER, PAPER, ETC.

[A.] 5342. Imray (Meister, Lucius und Brüning). Dyeing paper pulp. March 5.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 4972. Ray. Manufacture of common salt.* March 1.

„ 5151. Raschen, Wareing, and the United Alkali Co., Ltd. Purification of arsenical sulphuric acid and the obtainment of arsenic therefrom. March 2.

„ 5169. Laureau. Treatment of marine plants for the extraction of chemical, mineral and organic matters and their employment in arts and industries. March 2.

„ 5427. Ray. Manufacture of common salt. March 6.

„ 5428. Ray. Manufacture of common salt.* March 6.

„ 5478. Clemm. Conversion of alkali sulphate and bauxite or other aluminiferous material into alumina and alkali compounds containing sulphur.* March 6.

„ 5775. Johnson (Feld). Production of ferrocyanides from cyanogen contained in gases. March 9.

[A.] 5776. Johnson (Feld). Production of nitrate of ammonia. March 9.

„ 5852. Brünler. Apparatus for oxidising the nitrogen of the air for the production of nitric acid.* March 10.

„ 5901. Brünler. Utilisation of the nitrogen of the air by oxidation and conversion of the product into nitric acid or its salts.* March 10.

„ 6122. Pezzolato and Felice. Separation of sulphates of alumina and potash from solutions.* March 13.

„ 6142. James. Production of liquid air or other gases. March 14.

„ 6329. Barnes, Spence, and Spence and Sons, Ltd. Manufacture of titanium compounds. March 16.

[C.S.] 10,475 (1905). Morgan Crucible Co., Ltd., and McCourt. Treatment of non-metalliferous ores or the like for the separation of their constituents. March 7.

„ 10,722 (1905). Bale. Treatment of the pan scale of salt pans and its product. March 7.

„ 16,893 (1905). Shoop. Lime kilns. March 21.

„ 20,837 (1905). Grossmann. Manufacture of sulphate of ammonia. March 14.

„ 24,507 (1905). Teichner. Production of peroxide of hydrogen. March 14.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 4723. Emery and Emery. Kilns for firing ceramic ware. Feb. 27.

„ 5302. Pauls. Composition for making grinding tools.* March 5.

„ 5368. Touya. *See under* IX.

„ 5605. Sievert. Glass melting and pouring apparatus. [Ger. Appl., March 11, 1905.]* March 8.

[C.S.] 15,398A (1905). Bennett and Mastin. *See under* XIII*A*.

„ 18,545 (1905). Naylor. *See under* I.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 4661. Ford. Manufacture of artificial stone. Feb. 26.

„ 4662. Ford. Manufacture of artificial stone. Feb. 26.

„ 4663. Ford. Manufacture of artificial stone. Feb. 26.

„ 5132. Thompson. Manufacture of building and other blocks. March 2.

„ 5368. Touya. Artificial stone for grinding and abrasive purposes. March 5.

„ 5540. Gen. Cement Co., Ltd. (Passow). Manufacture of cement. March 7.

„ 5628. Tissington. Manufacture of cement. March 8.

„ 6034. Neal. Distemper to represent stone. March 13.

„ 6113. Jurschina. Manufacture of artificial stones, bricks, or like articles.* March 13.

„ 6333. Hadlington and Hinton. Continuous brick kilns and the like. March 16.

[C.S.] 4194 (1905). Boult (Reiche). Manufacture of hydraulic binding substances or cements. March 7.

„ 5765 (1905). Assoc. Portland Cement Manufrs. (1900), Ltd., Bamber and Layton. Manufacture of Portland cement. March 7.

„ 7043 (1905). Wolman. Composition of matter for impregnating wood. March 7.

„ 16,849 (1905). Earle. *See under* XIII*A*.

[C.S.] 20,296 (1905). Baur. Machinery for preparing or treating loam, clay, and the like. March 14.

„ 2704 (1906). Hall. Manufacture of faced or enamelled bricks, slabs, tiles and the like. March 14.

X.—METALLURGY.

[A.] 4796. Walker (Just). Recovery of precious metals from ores and other material.* Feb. 27.

„ 4904. Parnell. Smelting ores. Feb. 28.

„ 4999. Hodgkinson. Treatment of small mine or waste products of calcined iron ores for the more complete extraction of iron.* March 1.

„ 5029. Coupe-Annable, and The Ferro Alloys Synd., Ltd. Manufacture of ferro-chromium. March 1.

„ 5030. Coupe-Annable, and The Ferro Alloys Synd., Ltd. Manufacture of ferro-chromium. March 1.

„ 5031. Coupe-Annable, and the Ferro Alloys Synd., Ltd. Manufacture of ferro-molybdenum. March 1.

„ 5173. Cowper-Coles. Recovery of gold from cyanide solutions. March 3.

„ 5479. Lébédeff and Poméranzoff. Treatment of metallic sulphide ores preparatory to obtaining metals therefrom. March 6.

„ 5595. Kinchin. Iron alloy or compound. March 8.

„ 5655. Leaver and Buch. Treatment of flux skimmings of zinc, tin, or similar metal. March 8.

„ 5675. Cowper-Coles. Manufacture of standard silver. March 9.

„ 5716. Blackmore and Howard. Furnace for calcining or sulphating ores at low temperatures. March 9.

„ 5784. Fitzmaurice. Treatment of ores. March 9.

„ 5989. Hennay and Wilson. Treatment of metallic ores. March 12.

„ 6005. Justice (Bethlehem Steel Co.). Furnaces.* March 12.

„ 6210. Maunder. Smelting and treatment of complex, refactory and other ores. March 14.

„ 6426. Hadfield. Treatment of magnetic materials.* March 16.

„ 6484. Tropenhas. Manufacture of steel by the pneumatic process.* March 17.

[C.S.] 5260 (1905). Sulman, Picard and Ballot. Ore concentration. March 14.

„ 5817 (1905). Simpson (Simpson). Conversion of iron into steel. March 7.

„ 6468 (1905). Soc. Electrometallurgique Française. *See under* XI.

„ 6556 (1905). Hutchings. Method and apparatus for washing and concentrating metalliferous, diamondiferous and other deposits and tailings from ore crushing. March 21.

„ 7251 (1905). Bayliss, Jones and Bayliss, Ltd., and Milner. Puddling furnaces. March 7.

„ 10,312 (1905). Baillot. Cupola furnaces. March 7.

„ 11,268 (1905). Brayshaw. Process of hardening high speed steel. March 21.

„ 12,200 (1905). Haddan (Fellner und Ziegler). Process for treating finely-granulated or pulverised ores. March 7.

„ 13,297 (1905). King's Norton Metal Co., Ltd., Bayliss, Brownsdon and Smith. Treatment of gun barrels and other metallic surfaces for the removal of fouling therefrom. March 21.

„ 13,955 (1905). Zimmer. Apparatus for cleaning and separating minerals. March 14.

„ 19,525 (1905). Lean (Maschinenbau Anstalt Humboldt). *See under* XI.

[C.S.] 19,655 (1905). Dor-Delattre. Zinc furnaces. March 14.

„ 26,556 (1905). Campbell, Binnie and Reid (Smith). Apparatus for washing and separating coal and other minerals. March 14.

XI.—ELECTRO-CHEMISTRY, AND ELECTRO-METALLURGY.

[A.] 4683. Sanders. Manufacture of wire, bars and the like by electrodeposition. Feb. 26.

„ 4684. Cowper-Coles. Production of electrotypes. Feb. 26.

„ 4716. McDonald. Electrolytic apparatus.* Feb. 26.

„ 4726. Cowper-Coles. Manufacture of metallic foil or leaf. Feb. 27.

„ 5493. Fiedler. Secondary batteries.* March 6.

„ 6088. British Thomson-Houston Co., Ltd. (General Electric Co.). Electrodes. March 13.

„ 6089. British Thomson-Houston Co., Ltd. (General Electric Co.). Resistance material. March 13.

„ 6283. Kuehnrich. Electric furnaces. March 15.

[C.S.] 4668 (1905). Cowper-Coles. Manufacture of copper electrotypes and apparatus therefor. March 7.

„ 6468 (1905). Soc. Electrometallurgique Française. Electrical production of cast iron. March 21.

„ 7720 (1905). Leitner. Manufacture of accumulators. March 21.

„ 7903 (1905) Fennell and Perry. Electric accumulators or secondary cells. March 7.

„ 18,427 (1905). Lester. *See under* XVIII*B*.

„ 19,525 (1905). Lean (Maschinenbau Anstalt Humboldt). Magnetic ore separators. March 7.

„ 21,437 (1905). Kother. Electrodes for use in the manufacture of bleaching liquors. March 14.

„ 22,901 (1905). Bagnall. Electroplating vats. March 21.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 4688. Kosters. Manufacture of viscid or fluid emulsions of oils, fats or the like. *Feb. 26.

„ 6289. Chapman and Knowles. Lubricating compounds.* March 15.

[C.S.] 10,437 (1905). Brewer and Hardy. *See under* XIV.

„ 24,030 (1905). Kremer, and Ges. f. Abwässerklärung. Apparatus for the recovery of fats and the like. March 21.

„ 2680 (1906). Crowley and Payne. Lubricating oil. March 21.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(*A.*)—PIGMENTS, PAINTS.

[A.] 5015. Heide (Union Lead and Oil Co.). Apparatus for making white lead.* March 1.

„ 5048. Porter and Ward. Composition for cleaning painted surfaces. March 1.

„ 5999. Grasfland. Manufacture of paint.* March 12.

[C.S.] 14,202 (1905). Dunnett, Nelson and Nelson. Anti-fouling paints and compositions. March 14.

„ 14,611 (1905). Dunnett, Nelson and Nelson. Anti-fouling paint or composition. March 14.

[C.S.] 15,308A (1905). Bennett and Mastin. Manufacture of permanent pigments from glass. March 7.

„ 16,840 (1905). Earle. Colour washes for brickwork and other surfaces. March 14.

„ 1279 (1906). Potter. Paint. March 21.

(*B.*)—RESINS, VARNISHES.

[A.] 4678. Poppf. Manufacture of linoleum or like material. Feb. 26.

„ 5773. Linoleum Manufacturing Co., Ltd., and Vincent. Apparatus for the manufacture of linoleum, &c. March 9.

[C.S.] 6751 (1905). Lederer. Solutions of organic compounds suitable as lacquers, varnishes, waterproofing and impregnating media, and for the manufacture of films, filaments and insulating materials. March 7.

„ 17,187 (1905). Morris. Manufacture of substitutes for felt, linoleum, oilcloth, leather, &c. March 7.

(*C.*)—INDIA-RUBBER.

[A.] 4692. Gratz. Processes for obtaining pure caoutchouc, guttapercha and the like. [Ger. Appl., Feb. 21, 1906].* Feb. 26.

„ 4701. Grätz. Processes for obtaining caoutchouc. [Ger. Appl., Feb. 2, 1906.]* Feb. 26.

„ 5486. Soc. en Commandite pour actions Michelin et Cie. Process of utilising rubber waste. [Fr. Appl., March 30, 1905.]* March 6.

„ 6183. Granier and Froger-Delapierre. Compound for coating caoutchouc to preserve its natural properties. March 14.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 5169. Laureau. *See under* VII.

„ 5407. The Bakau Co., Ltd., and Meikle. Extracting soluble matter from bark, wood and the like and apparatus therefor. March 6.

„ 6516. Spencer and Abbott. Leather finishing composition. March 17.

[C.S.] 10,437 (1905). Brewer and Hardy. Process and apparatus for extracting grease and oil from skins and hides. March 7.

„ 16,432 (1905). Luther. Manufacture of glue March 21.

„ 17,187 (1905). Morris. *See under* XIII*B*.

„ 22,525 (1905). Collardon. Manufacture of plastic masses from casein and the like. March 21.

„ 24,487 (1905). Oakes. Process for treating hides March 7.

„ 135 (1906). Harrison (Turner Tanning Machine Co.). Machine for treating hides, skins and leather. March 7.

„ 3516 (1906). Oakes. Process for treating hides March 7.

XV.—MANURES, ETC.

[A.] 6429. Chisolm. Fertilisers.* March 16.

[C.S.] 5618 (1905). Crone, Taylor and Williams. Manufacture of fertilisers and apparatus therefor March 7.

XVI.—SUGAR, STARCH, GUM, ETC.

[A.] 5323. De Vecchis and Sani. Complete extraction of inulin from tubercles.* March 5.

[A.] 6009. Drost. Mashing apparatus for promoting the crystallisation of sugar masses and for intimately mixing other pulpy masses with diluting agents.* March 12.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 5135. Vloeberghs. Process of fermentation.* March 2.

,, 5147. West and Co., Ltd., and Webster. Apparatus for collecting and treating gases and other volatile products of fermentation. March 2.

Official Notices.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY. ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906.

The attention of Members is drawn to the Notice which accompanied the February 15th issue of the Journal.

The General Secretary will be obliged if those members, who have made arrangements directly with the Congress Committee in Rome, will forward their names to the Society, in order that arrangements may be made for a headquarters in Rome. It would also be of service if they would indicate their contemplated date of departure and proposed route, and also whether they have a preference for any particular hotel in Rome

Death.

Claudet, Francis G., Ennismore, Willesden Lane, London, N.W. March 13.

Meeting held at Birmingham, on Thursday, Feb. 15th, 1906.

PROF. FRANKLAND, F.R.S., IN THE CHAIR.

THE CALORIMETRY OF VOLATILE LIQUIDS.

BY WALTER ROSENHAIN, B.A., B.C.E.

In view of the important uses of volatile liquids as fuel for explosion motors and other purposes, a method has been devised for the accurate determination of the calorific value of such substances by direct combustion in oxygen. The method described below is primarily intended for use with the coal-calorimeter designed by the author and fully described elsewhere (*) but is, with minor modifications, applicable to any form of direct combustion calorimeter. The author's calorimeter belongs to that class in which the combustible substance is burnt in a current of oxygen under a pressure only slightly higher than atmospheric; in such an instrument it is impracticable to burn a liquid either directly in a crucible, or by means of an asbestos or other wick, since the heat evolved during the earlier stages of the combustion rapidly vaporises the bulk of the liquid and either extinction or explosion results. A somewhat better method, which has found some application in practice, consists in absorbing the liquid in either powdered kaolin or in a piece of porous refractory material, such as biscuit porcelain or fire-clay. Apart from the serious errors that would arise from evaporation losses in the case of volatile liquids, this method has the great disadvantage that the close contact of the combustible with non-inflammable and comparatively cold material renders the combustion incomplete, and a small residue of unburnt liquid is always left in the pores of the absorbent medium. This fact suggested that the absorbent substance itself should be completely combustible, and a suitable material has been found in pellets of dry and somewhat compressed cellulose. A large number of pellets of approximately equal weight can be prepared from a single batch of material, and by making a few calorimetric combustions of these pellets in the dry state the calorific value per grm. can be obtained. In practice, the cellulose material used is found to have a calorific value of about 4000 calories per grm., while a pellet weighing 1 grm. will absorb about 0·5 grms. of petroleum, having a calorific value of about 11,000 calories per grm., the heat given out by the combustion of the pellet and by the oil under test being thus about equal.

For such liquids as heavy mineral oils and other less volatile liquids this method, without further precautions gives results accurate to ½ per cent. when used with the author's calorimeter, but the more volatile liquids such as petrol, alcohol, amyl acetate, &c., evaporate so rapidly that the loss in the course of the transfer from the balance to the calorimeter is much too large to be neglected (see Table I.). The pellet, after saturation with the volatile liquid, was therefore wrapped in thin tin-foil. The coating of tin-foil almost entirely stops evaporation, while it does not interfere with the combustion, the tin-foil igniting readily and burning away with the rest of the pellet.

The actual losses by evaporation from bare and wrapped pellets saturated with volatile liquids (petrol, amyl acetate and ether) are shown in Table I. It will be seen that even with so extremely volatile a substance as ether, the loss is only of the order of 1 per cent. in five minutes after the first five minutes have elapsed.

TABLE I.

Liquids.	Temp	Weight.	Loss at end of 5 mins.	Loss at end of 10 mins.	Loss at end of 15 mins.
	°C.		Per cent.	Per cent.	Per cent.
Petrol					
Bare	15	0·359	19·0	32·0	46·0
Wrapped	15	0·386	0·7	1·1	1·3
Amyl acetate					
Bare	17	0·308	5·5	9·4	14·0
Wrapped	17	0·387	0·6	1·0	1·4
Ether					
Bare	13	0·469	31·0	51·0	66·0
Wrapped	13	0·493	2·0	3·6	4·6

The evaporation during the first five minutes is sometimes found to be somewhat irregular, but a steady rate of loss is then established. The rate of loss can be ascertained by weighing the wrapped pellet five and ten minutes after first wrapping, and if the time elapsing between the last weighing and ignition in the calorimeter be noted, a correction for the small amount of loss can readily be applied. As the time in question need never exceed five minutes, the correction is always small.

In applying this method, it is, of course, necessary to know the allowance to be made for the heat evolved by the combustion of the tin-foil used in wrapping the pellet. The weight of tin-foil used is about 0·18 grms., and the calorific value under the circumstances of such a combustion lies near 2200 calories per grm., so that the total heat due to the tin-foil is of the order of 400 calories; consequently a small error in the estimation of the calorific value of the tin does not very seriously affect the accuracy of the result. In practice the calorific value of the tin cannot be determined with any great accuracy, since it is found not to burn quite completely—a minute globule of metallic tin is nearly always found in the calorimeter after the combustion. Some of these globules were carefully cleaned and their weight found to be about 0·01 grm., therefore involving an error of about 20 calories. If the stream of oxygen in not properly directed, or thick lumps of tin are formed by careless wrapping of the pellet, much larger quantities of tin may remain unburnt or be again reduced during the combustion. For the determination of the calorific value of tin used by the author in the examples given below, a combustion of a wrapped pellet of a substance of known calorific value (amyl acetate) has been employed, the correction due to the presence of the tin being easily calculated from the data thus obtained.† The results obtained in this way agree with the calorific value of tin found by the combustion of wrapped dry pellets.

(*) Phil. Mag., October, 1902; this J., 1902, 1472.

(†) The use of aluminium foil in place of tin foil has been suggested by Mr. Rees, and if foil of suitable thickness is obtainable, this may prove preferable to tin, as the risk of reduction would be absent and there would be less tendency to form organic compounds.

The method, as here described, is readily applied to such liquids as light mineral oil, petrol, alcohol, &c. With some substances, such as ether and chloroform, the tin enters into combinations which are not destroyed during combustion, so that the results are vitiated, while with benzene it has not yet been possible to avoid the deposition of soot. With those liquids, however, whose calorific values are likely to be required commercially, these complications do not arise, so that the method described affords a rapid and accurate means of testing.

The following examples of actual determinations will serve to illustrate the procedure and calculations employed :—

Determination of calorific value of tin foil, by combustion with dry pellet.

Weight of tin foil = 0·161 grms. Calorific value of dry pellet per grm. = 4210 calories.
" dry pellet = 1·053 "

Water-equivalent of calorimeter with water = 2450 grms.
Observed rise of temperature (corrected for radiation) = 1·96° C.
Total calories found = 2450 × 1·96 = 4800
Calories due to pellet = 4210 × 1·053 = 4430.
Calorific value of tin foil = 4800 − 4430 = 2290 calories per grm.

$$\frac{}{0{\cdot}161}$$

Two other determinations gave 2340 cals. and 2350 cals. respectively.
Mean value = 2330 calories per grm.

Determination of calorific value of amyl acetate.

Weight of pellet = 1·181 grms. Calorific value of dry pellet = 4210 cals. per grm.

" tin foil = 0·183 " Calorific value of tin foil = 2330 cals. per grm.

" amyl acetate = 0·502 grms Water equivalent of calorimeter (corrected for loss by evaporation) + water = 2450 grms
Observed rise of temperature (corrected for radiation) = 3·86° C.

Total calories found = 3·86 × 2450 = 9460
Calories due to pellet = 4210 × 1·181 = 4970.
" due to tin foil = 2330 × 0·183 = 430.

$$\text{Cal. value of amyl acetate} = \frac{9460 - 4970 - 430}{0{\cdot}502}$$

= 8080 calories per grm.

Other determinations gave 7950 and 8030 calories per grm
Mean value = 8020 calories per grm
Value given by Faver & Silbermann (Landolt's tables) = 7970 cals. per grm.
Two determinations of a sample of petrol gave 9970 and 9950 cals per grm.
Two determinations of a sample of methylated spirit gave 6200 and 6230 cals. per grm.

For much assistance in working out the details of the method and in making the determinations quoted above, the author is indebted to Mr. W. J. Rees.

Discussion.

The Chairman said it was very necessary that the calorific values of liquid fuels should be made more widely known, as an extraordinary amount of ignorance prevailed, even amongst scientific persons, as to the relative heat efficiencies of different combustible liquids. He would like to ask Mr. Rosenhain how the results obtained with his apparatus compared with those yielded by the Junker, the Wright, and the bomb calorimeters respectively. He would also like to know whether, in the figures given, any correction for evaporation had been applied, or whether, in practically using the calorimeter, the combustion could be so rapidly started that the weight of substance burnt might be taken as that which had actually been determined with the balance. He would further like to know whether Mr. Rosenhain had made any systematic experiments as to the possibility of burning hydrocarbons without smoke. He understood that in the case of benzene the combustion could not be effected without smoking taking place, but it would be interesting to know whether and, if so, at what terms in ascending other series of hydrocarbons combustion with smoke was unavoidable.

Mr. A. E. Tucker said it seemed to him that in the interval between the admission of the saturated pellet and the firing of it, there was an opportunity for an appreciable amount of such a vapour as petrol to mix with the oxygen or air used and either escape or lead to an explosion. Had such an objection been experienced? Mr. Rosenhain alluded to other forms of calorimeter as sometimes leading to the smothering of the flame. Some short time since he had occasion to determine the calorific values of different makes of petrol, and had used a Junker instrument. He found no difficulty in gasifying the petrol and then burning it through an ordinary Bunsen burner. The results he obtained were very satisfactory and, in his opinion, the operations with this instrument are much less liable to error than in Mr. Rosenhain's calorimeter, in which there appears to be so many required corrections. To gasify the petrol he made what was really a wick carburretor with an ordinary circular lamp wick. A measured volume or weight of petrol was run on to this wick and air, at a suitable rate and pressure, was driven through the wick. This gave an easily controlled flame at the burner, and the estimation was made in the ordinary way. His opinion was that while Mr. Rosenhain's form of calorimeter was suitable for solid fuel, the Junker instrument was preferable for volatile liquids. In Mr. Rosenhain's instrument the necessary corrections were numerous, and only a very small weight of the liquid to be tested could be taken, while with the Junker any quantity could be taken and the accuracy obtained would be correspondingly greater.

Dr. Davidson said that another source of error was using the red hot platinum wire. He found in experiments with closed vessels that it was really a very serious error, and had to be taken account of. It usually amounted to 1 per cent., and he had to determine it directly. Of course, it could be determined by electrical methods. But of this form of calorimeter, he thought Mr. Rosenhain's is undoubtedly the best. He had had experience of several, and certainly admired the mechanical contrivance of the calorimeter very much, but the searching for the coal or other combustible with a red hot wire was open to very serious objection. There were several forms of calorimeter in which the red hot platinum wire was used for igniting the coal or other combustible, and he thought in that type there was apt to be a very serious error because the substance was not always ignited at once. The usual practice was to send a current through the wire again and burn them.

Mr. Alcock suggested the use of silver leaf. No correction would have to be made for silver if it could be rendered sufficiently non-porous.

Mr. L. Archbutt asked Mr. Rosenhain whether he had endeavoured to burn these volatile liquids in the bomb calorimeter. He considered the bomb calorimeter preferable from many points of view. It was simpler, and probably more accurate. Looking at the large volume of gas bubbling through the water all the time, one wondered whether some heat was not carried away, and also whether all the carbon was burnt to carbon dioxide. No doubt Mr. Rosenhain had investigated that point.

Mr. Rosenhain, in reply, said the Junker calorimeter was a very useful apparatus for burning anything that could be burned as a flame, and the results, he had no doubt, would agree very closely. With regard to the bomb calorimeter, he thought that its advantages were greatly over-rated. The point to which he objected in the bomb was that the transfer of heat from the place where it was generated by the combustion to the place where it was measured, had to take place through a steel vessel of considerable thickness—thick enough to resist the very considerable pressure involved by the combustion which took place inside that bomb—and the transference of the heat from a gaseous atmosphere to the steel, and from that in turn to the liquid was necessarily incomplete in anything like the time which could be allowed for it. That was the reason why he thought that what one might call the atmospheric pressure calorimeter had certain definite advantages. Although in his original account of the calorimeter he advocated the use of the red hot wire for searching for unburnt coal at the end of the combustion, in the case of coal he had long ago abandoned that practice, because there never was any unburnt coal if the experiment was properly

done. In the course of 50 or 60 experiments he looked for unburnt coal, but he never found any. As regards the correction for the heat put into the calorimeter by the electric current that was allowed for in the initial calibration. The calorimeter could be calibrated by the combustion in it of a substance of known value. Provided that the red hot wire was used for a standard length of time in all cases, then in future no further correction was needed. The amount of heat to be put in by the wire was allowed for in the figure for the water equivalent. That was really the most convenient way, provided that care was taken always to keep the wire hot for a definite length of time.

As regards the risk of explosion, referred to by Mr. Tucker, a glance at his figures would show that the amount of evaporation going on even in ten minutes would be so slight that there was no risk whatever from explosion. The suggestion to use silver leaf had occurred to him long ago, but the difficulty was that silver leaf would not ignite. If silver foil was used he doubted very much if one would succeed in doing more than melting it, and possibly burning the pellet in the hole that was melted through the silver, but a wrapping that burnt away was preferable. The systematic investigation of the hydrocarbons in regard to smokeless combustion was matter for the future. As yet we had not learned the best way to arrange the oxygen supply. Petrol could be made to smoke by arranging the oxygen badly, and if the oxygen could be made to play upon the benzene pellet the combustion would be complete in that case also. The point raised as to the completeness of the combustion in the calorimeter had been carefully tested by analysis, and he had found that there was no trace of carbon monoxide formed if the oxygen was really saturated with moisture. The smokelessness of the combustion, the absence of smell, and the absence of carbon monoxide were very good evidence that the combustion was really complete. Another advantage was that the instrument was comparatively inexpensive compared with the Bomb, but there was no doubt whatever that this method of using wrapped pellets was applicable to any form of calorimeter.

MR. A. GORDON SALAMON IN THE CHAIR.

THE IGNITION OF NITRO-COMPOUND EXPLOSIVES IN SMALL-ARM CARTRIDGES.

BY W. D. BORLAND.

The discussion of the subject of the ignition of nitro-compound powders in small-arm cartridges acquires an added interest when it is remembered that it is now exactly 100 years since Forsyth proposed to replace flint and steel by a percussion powder consisting of "oxymuriate of potash, sulphur and carbon," and thus laid the foundation for future developments. His invention was dormant for nearly the first third of the 100 years, the second third saw various developments in connection with black powder ignition, the last 30 years have witnessed the growth of nitro-compound explosives with the more critical demands which they make for properly regulated conditions of ignition.

A glance at the velocity tables alone, given in this paper, indicates that whilst with carefully manufactured explosives for ballistic purposes, there is a considerable latitude permissible in ignition and other conditions of use, yet even within the limits of correct behaviour there are varying degrees of excellence and to trace out the factors which make for excellence or failure is an interesting study.

When the gun striker falls upon the cap of the cartridge a variety of results may follow. If the metal of the cap shell be too thick in proportion to the blow or the composition insufficiently sensitive, there may be a miss-fire. If the blow be of minimum strength and just sufficient to develop enough heat, the composition immediately between anvil and striker will commence to burn, and if the composition be a slow one, and especially if it contains inert substances, it may happen that combustion takes place so slowly through the mass that heat is dissipated as quickly as produced, and the charge burns or fumes quietly without incandescence or noise. With a more rapid composition the whole may burn, developing gas and heat sufficiently fast for the products to be expelled as a low pressure jet of compressed gases and molten matter, potassium chloride, antimony oxide or sulphide, &c.

With the ideal composition and striker blow the whole charge burns at a rate proportioned to the heat receiving capacity of the explosive without undue waste on the case, the jet containing solid matters in regular distribution, which, by reason of their high specific heat per unit volume, are able to convey to the explosive sufficient quantity of heat and at a suitable temperature and volume to start its decomposition.

Were the igniter wholly gaseous, such as fulminate of mercury, then the heat units necessary would be delivered in large bulk, and at such a high pressure that the cap shell would be unable to withstand setting back into the striker hole. Moreover, the enormous pressure of the jet would entirely disturb the carefully proportioned initial surface of the explosive, to say nothing about the risk of detonation. Mixing with powdered glass, as in earlier days, makes matters worse; heat units are absorbed by the glass, and, for the same number of heat units usefully given to the explosive, the volume of gas becomes larger per heat unit than before.

Turning away from fulminate, and trying 3 mols. of potassium chlorate and 1 mol. of antimony sulphide, the converse result is obtained, *i.e.*, too little gas in proportion to heat units, insufficient sensitiveness, and too great bulk for the ordinary cap shell. The characteristics of this mixture are:—457 grm. calories per grm.; 95 c.c. of gas; temperature of combustion, 1860° C. Trying the effect of 3 mols. of mercury fulminate and 2 mols. of potassium chlorate, producing 668 grm. calories per grm., and 244 c.c. of gas, an improved proportion of gas to heat is evident, but the violence of the mixture condemns it. Finally, a compromise between mercury fulminate and antimony sulphide is adopted, and varying relative proportions of these materials, together with potassium chlorate, are now usually employed.

Or other materials may be used, such as (*a*) 4 mols. of basic thiocyanate and 20 mols. of potassium chlorate; (*b*) 1 mol. of lead thiocyanate and 3 mols. of potassium chlorate, producing per grm. respectively:—(*a*) 551 grm. calories and 151 c.c. of gas; (*b*) 585 grm. calories and 163 c.c. of gas. Or powdered glass, sulphur and meal powder, may be added, or, as recently suggested, (*) chromates of lead or mercury, together with fulminate of mercury and powdered glass or lead peroxide may be employed (though no opinion is expressed as to the stability of such a mixture), but, whatever the material be, the whole course of events from striker blow to explosive is as follows:—

Ignition of portion of composition affected by striker blow.

Propagation of explosion through mass of composition and development of total heat of combustion.

Heat absorbed by cap shell, cap chamber and anvil.

Heat lost in performing work on cap shell.

Heat lost by effect of passage of gases through fire-holes.

Temperature lost by work required to move solid particles of the products, *i.e.*, imparting kinetic energy, but restored when particles come in contact with the explosive.

The final result is net calories delivered in time and at temperature dependent upon rapidity of reaction and temperature of combustion and in a more or less voluminous form. Thus, dealing with the gaseous products alone, carbon dioxide and sulphur dioxide will carry 37

(*) Eng. Pat. 27,006, 1904.

per cent. more heat than oxygen, nitrogen, or carbon monoxide at same temperature and of same volume.

The rapidity of flow of the jet determines rapidity of delivery of heat units to the explosive, the temperature of the jet is also an essential element of rapidity of heat interchange, whilst the proportion of gases to solids has its bearing on volume and temperature for a given number of heat units. Under the Explosives Act the maximum weight of composition is limited to 0·5 grain or, if not more than 25 per cent. of fulminate of mercury be present, to 0·6 grain. The minimum is determined by the quantity which will make a coherent disc in the cap shell, therefore, within these limits the composition must be adjusted to give total heat within limiting temperature of combustion of, say, 2400° to 3200° C., based on present knowledge, together with a suitable volume of gases, varying according to the colloidal or fibrous character of the explosive.

No single one of these factors can be taken by itself in the valuation of an igniter for a particular purpose; they must be considered in their mutual relation to each other and in connection with known facts as to composition, specific heat, conductivity, nature and extent of initial surface, and increasing or decreasing surface of burning of the explosive.

There is no suggestion that even the most accurate knowledge of individual functions can ever take the place of ballistic trials. With military rifle ammunition especially, once the given explosive and igniter are tuned together, then rigid adherence to specification does, undoubtedly, work out with success. But suppose a new explosive to be in course of adaptation to a particular arm, the igniter which proved perfectly satisfactory with the old explosive may be found unable to develop the anticipated qualities of the new one. The question will then arise, shall the igniter be adapted to the explosive or *vice versa*. If the former course be determined, then knowledge of individual functions will be found of value and will materially assist the solution of the question.

Again, in powder standardisation the igniter, is as much in evidence as standard solutions are in the laboratory, and apart from actual manufacture of ammunition, the explosives manufacturer is forced to regard the igniter as a test reagent, if his product is to preserve the necessary commercial latitude of action under the varying conditions, which obtain with sporting cartridges to a far greater extent than with rifle, and especially service ammunition; for with sporting arms provision must be made for every calibre of weapon, varying proportions of explosive to projectile, different materials of cases and wads, different co-efficient of friction and resistance for different sizes of shot, and, above all, for explosives highly different in chemical and physical qualities, demanding the fulfilment by the igniter of conditions precedent for efficient action.

The object of this paper is not to lay down a specification of what constitutes the ideal igniter, but rather to present results in a tabulated form and indicate the general lines and methods on which research seems profitable, endeavouring also to ascertain whether data obtained by thermo-chemical calculations may be applied in a practical manner. The difficulties of research are considerable, the igniter performs its functions in a time which cannot well be more than 0·001 second, its maximum weight of charge may not exceed 0·6 grain (0·0392 grm.), to make investigations of any use, such must be undertaken under the conditions which obtain in the cartridge case, so far as cap chamber, anvil and fire-holes are concerned, and instruments which are ordinarily available for measurements of temperature, or heat units, are found to be either too delicate to withstand explosive action, or too gross to take account of variations with so small a quantity of material.

During the whole history of nitro-compound explosives, experimental work has not been wanting; frequent references to the subject will be found in various journals especially those devoted to shooting and explosives; the names of Griffiths, Reid, Toms and Brownsdon in England are associated with published investigations of this subject.

The author's own work has included the following:—(*a*) 1892: Description of apparatus for measuring sensitiveness to blow, effect of shape of striker, effect of angle of striker to cap, time of travel of cap products and energy of explosion. (*b*) 1896: photographic records, (*c*) the use of thermo-couples, and (*d*) a method of recording duration of incandescence upon a sensitive plate revolving at a high speed; and more recently, as will be described, a spectro-photometric method of observation, with a view to elucidation of temperatures; this physical work has been collated with analytical work on compositions and ballistic trials.

No investigation can be regarded as satisfactory which does not deal with the following questions:—(*a*) Composition either determined analytically or accurately stated in the case of manufacturing trials. (*b*) Relation of gaseous and solid products. (*c*) Rapidity of application. (*d*) Total heat. (*e*) Temperature. (*f*) Regularity and a latitude under varying conditions. (*g*) And the relation of observed to calculated results.

Details of methods for chemical analysis of compositions need not be here discussed as they are of a comparatively simple character, but, for the individual analyses of caps, the volumetric method for the estimation of mercury fulminate described by H. W. Brownsdon (this J., 1905, 381) proves satisfactory. The determination of the relative proportions of gaseous and solid products of the igniter is carried out by the author in the following manner:—The percussion cap is accurately weighed, inserted in the particular type of cartridge in which it is to be used, so that all the details of cap chamber, anvil, and flash holes, are those of practical working and the cartridge case closed with a plug, the plug being of lead if a metallic case be used and of asbestos and felt wadding if a paper case be employed. The total cap, case and plug are then weighed, and after weighing fired in the appropriate rifle or sporting gun. After cooling for ten minutes (though in fact less is needed) a clean hole is stabbed in the wall of the case and the gaseous products allowed to escape and become replaced by air, this operation only requiring a few minutes. The solid products, including condensed mercury, are deposited upon the internal walls of the case, and on re-weighing, the loss represents permanent gases. If it be desired to estimate the condensed mercury, this is effected by heating the stabbed case at 100° C. until constant weight is obtained; but if this estimation is desired the case must be metallic and not of paper.

The weight of composition originally present in the cap is determined by removing the fired cap from the cartridge and weighing and subtracting the figure from the original weight.

The figures obtained in a series of estimations form a very good check upon regularity of manufacture and combustion; they have also been found to run in excellent agreement with those demanded by theory, the calculated results given on Table IV. having all been checked by direct estimations by the above method. It is, however, desirable to offer a word of caution when paper cartridge cases are used; these are not always truly gas-tight, and in the first rush of gases mercury vapour may be carried away and be thus estimated as permanent gas. To avoid any possibility of doubt on this score metallic rifle cases, in which the sporting cap chamber is inserted and which will therefore receive the sporting cap under its own conditions of anvil and flash-hole, are preferably employed.

The problem of the *comparison of velocities of application of the igniter to the explosive* cannot be expressed in quite such simple terms as the foregoing, but it is found in practice that there are two methods of investigation which lead to valuable practical results, one being a a species of crusher gauge test and the other dealing with duration of incandescence of the solid products.

In the first method, which was described by the author

(*a*) This J., Vol. XII., 1893, p. 709.
(*b*) Sporting guns and gunpowders, pub. Horace Cox., 1900, p. 210—220.
(*c*) This J., Vol. XXIV., 1905, p. 381.
(*d*) Quelques notes sur les poudres sans fumée. H. Quersin Imprimerie Vanbuggenhoudt. Bruxelles. 1899.
(*e*) Experts on guns and shooting. G. T. Teasdale-Bucknell

in 1892, the cap *in its own cap chamber* is inserted to form a gas-tight fit in the end of an accurately bored tube, in which a plunger with 0·0005 in. clearance is placed, a crusher lead 0·325 diameter by 0·500 length, being placed at the end of the tube opposite to the cap chamber. In the case of large readings being expected, a crusher copper, preferably of the Holden conical form is used in place of lead.

The ejection of the cap products drives the plunger upon the crusher with greater or less velocity according to the gas volume, temperature and rapidity of reaction, and the measured crushing is referred to accepted standard tables.

Taking, for example, two similar compositions, say, A^3 and A^4, where the only difference was that of aggregation and intimacy of mixture of the ingredients, A^4, by reason of its better incorporation, produced an energy figure corresponding to the crushing effect of a weight of 395 lbs., whilst the figure for A^3 is 345.

Bearing in mind that the total amount of material in these particular trials is only 0·0324 grm. and that the heat capacity of the metal of the apparatus, cap and cap chamber is relatively unlimited, the conclusion drawn is that the velocity of production and discharge of the gaseous and solid matters is greater in A^4 than A^3, the reaction taking place so quickly in A^4 that heat losses are less than in A^3. This became very evident in the spectro-photometric test described below, in which the caps are fired in glass tubes for observation, A^4 frequently blew the tubes to pieces, whereas with A^3 this never occurred.

This is shown by comparing B and E; here equal volumes of gas are produced, yet, in spite of the grm. calories per cap being greater in B than in E, the energy figure is 299 for B against 358 for E. The larger percentage of mercury fulminate in E and also a larger area of flash-hole explains the more rapid ejection.

In comparing caps of the same composition and weight different energy results can only be ascribed to different rates of combustion, but if weights vary, then the results should be referred to unit weight. With compositions differing in their characteristics the ratio of energy to total heat is the most useful expression, whilst if deductions are to be drawn as to chamber pressures produced by various igniters with semi-colloidal powders in sporting guns, gas volume must also be taken into account, as this determines the initial amount of explosive subjected to ignition.

The investigation of the duration of incandescence of the solid products was first described in 1896. It consisted in firing the cap into a glass tube to prevent air cooling and exposing a photographic plate revolving in the plane of its surface to the radiations of the incandescent solids, a screen with a slit in it being placed between the tube and the plate. The plate being stationary and the cap fired, only a narrow band of image the width of the slit was produced on development, but when the plate revolved at 3000 to 4000 revolutions per minute the band of image became V-shaped, the angle of increase being measured by projecting the image by an optical lantern on a circular protractor and from that, the velocity of revolution being known, the duration was arrived at.

The absolute determination of *quantity of heat per cap* is an extremely difficult matter owing to the small quantity of material to be dealt with at a time, and to the heat losses which take place when a cap is fired in a cartridge case and in contact with firing mechanism. The figures, therefore, given in this paper are the calculated ones, but they have been compared in their relation to each other by flashing on thermopiles. A bismuth-antimony pile of 25 couples, 0·2 by 0·1 by 1 in., is a robust instrument and gives concordant readings from day to day provided the galvanometer is standardised with a Clark cell used in conjunction with a high resistance, about 200,000 ohms being necessary. Readings of increased magnitude can, of course, be obtained by using a large number of couples, in practice a pile of 50 couples of bars, 0·1 by 0·1 by 1 in., is employed as well as the 25 couple instrument. The value of this method lies in the fact that the thermopile indicates not only quantity differences but also time differences, and magnifies up irregularities of action, and is, therefore, a most delica test for regularity of manufacture. Where the tim element is preferably eliminated, the thermopile face covered with a metal plate insulated from the pile b mica or lacquer, the plate acts as an accumulator an rapidly passes on its heat to the thermopile, producin galvanometer readings which give good agreement wit calculated figures for quantities of heat per cap, not onl in the comparison of individuals of the same compositio and velocity of reaction, but also of different materia of different rates of combustion.

Passing to *temperature* valuations the question a once arises, how can these be dealt with withou *quantity* of heat acting as a disturbing influence. If a endeavour be made to estimate the temperature of th jet in a closed vessel (such as the cartridge case whe loaded with powder undoubtedly corresponds to) th cooling effect of the material of the vessel at once make any such procedure dependent upon quantity of heat.

If the estimation be in an open vessel or in air, the the objection presents itself that the gases are expande and thereby cooled, cooling the solids with them Even then, a thermometer or thermo-junction must b of infinitely small weight if heat quantity is to have n effect, moreover, the further question of galvanometer inertia enters in.

Any method of temperature valuation must, therefore, be independent of mass, and this led to radiation observations being undertaken, in the first instance photographically, and later spectroscopically.

The relation of calculated temperatures of combustion of various carefully-made practical mixtures to observed results was taken as the basis of work, it being argued that if a sufficiently accurate relation of observed to theoretical results could be discovered, and also if this relation would hold good for various materials, there would be not only a check upon the correctness of the formulæ assigned to each reaction, but a means of valuing temperatures of unknown mixtures.

Taking the view that the practical igniter (which excludes mercury fulminate used alone) is really a high-pressure gas jet containing incandescent solid matters, and looking on the cap as a sort of retort in which a reaction takes place with considerable violence and ejects the contents through the neck, *viz.*, the flash or fire holes, it seemed that photographs of the ejected mass would record the shape of the incandescent jet and the completeness with which the solids are broken into spray or otherwise ejected in a more coherent form. It was found that caps producing faulty spray production, as shown photographically, were always unreliable in their effects on ballistics, but it was also found that there were enormous differences of intensity of photographic image, and that whilst many caps gave good photographs on rapid plates with a lens aperture of f2·2, others required with the same plates an aperture of f0·7 to yield the same density; further, that low calculated temperatures of combustion were always associated with feeble photographs and incandescence of a yellow colour, whilst increased calculated temperatures of combustion were co-related with increased density of photographic image and incandescence passing towards whiteness. Spectroscopic investigation failed to reveal any specific spectra accounting for the varying intensities and colours, in fact other than the sodium D lines, the spectra observed in some thousands of instances have only been continuous spectra due to hot solid bodies. It was also observed that cap composition, producing yellow incandescence and feeble photographic effect, produced continuous spectra of low intensity throughout, whilst with incandescence tending to whiteness and strong photographic effect, the continuous spectrum tended to brilliancy. Following the principles adopted in optical pyrometry, observations were then made by means of a shutter eye-piece of various separate portions of the spectrum comparing intensities of radiation, and again it was found that throughout the spectrum the portions varied in brilliancy in accordance with photographic activity, ordinary visual colour examination and calculated temperature.

A right and left-handed reflecting prism capable of passing into the spectroscope two fields in juxtaposition

from two sources of radiation without absorbing more of one than of the other was constructed for the purpose, and direct comparisons made of the intensities of radiation emitted by the incandescent solids of the cap and those given by a known source of light.

After many trials a small incandescent lamp in conjunction with a milliamperemeter and variable resistance, was found to be the most convenient as a standard radiant. Precautions now of a well-known sort for "ageing" the lamps were naturally adopted, to obtain constancy of radiation for given current consumption.

The question then arose whether the radiation intensities could be expressed in terms of temperature of the standard radiant. Application was made to M. Féry, whose work in optical pyrometry is well known, and an optical pyrometer of his design * with specially open scale was placed at the disposal of this work. It thus became possible to calibrate (and check from time to time) the incandescent lamp for temperature in terms of current in milliamperes, as in Holborn and Kurlbaun and also Féry's own method, and so to refer intensities to a standard.

In carrying out this investigation the cartridge case is cut off near the base and inserted in the end of a glass tube, 5 ins. by $\frac{3}{4}$ in. internal diameter. † The exact dimensions of the tube have not, within the limits of observation, been found to influence the results, and up to a distance of about 3 ins. from the fire-holes or hole, the particular point observed is not very material, though as a matter of fact a distance of $1\frac{1}{2}$ ins. for sporting caps and 2 ins. for rifle caps (with their larger charges) is usually adopted. The tube method is chosen in preference to observation of the flash holes on account of the greater ease of sighting and diminished risk of damage to spectroscope.

The spectroscope preferred is of the constant deviation type as it has fixed tubes, and it is easy to pass through the spectrum without altering adjustments. The spectroscope slit must be fairly wide on account of the brief duration of the spectrum, the necessary width of slit depending upon the distance of spectroscope from firing tube. Care must be taken to keep the distance of standard radiant from spectroscope the same as that of firing tube from spectroscope.

Trials have also been made based upon the observation of length of spectrum visible when a narrow slit is used. For this purpose either an eye-piece scale in the constant deviation instrument or the ordinary reflected millimeter scale in the case of the ordinary spectroscope is necessary. On observing the radiations from the firing tube, the visible spectrum appears to extend more or less away from the red according to calculated temperature of combustion. It is known that even at 1000° C., from Lummer and Pringsheim's curves, the wave length of maximum energy is at 235 outside the visible spectrum, so this method really resolves itself into comparison of visibility in the blue, and is not so convenient or accurate as the comparison of red intensities.

The figures are given in Table IV. for intensities of radiation in terms of temperature of the comparison incandescent filament show to what extent they are in agreement with temperatures calculated by Le Chatelier and Mallard's formula, the mean being 47·1 per cent. under the conditions adopted, the difference between the calculated and observed being accounted for by the heat losses referred to at the commencement of the paper, to "black body" correction for the solids and most of all to temperature reduction due to adiabatic expansion of the gaseous products.

That the solids have not black body emissivity is found by observations in the green, where intensity of the incandescent solids is found to be slightly higher than in the red. That is to say, when agreement *in the red* with standard radiant has been arrived at, on shifting the field of observation to the green, there is found to be greater intensity from the cap products. But, with the exception of C, practically the same materials are dealt wit in this series of trials, in fact even with C the large pe cent. of potassium chloride probably brings about ver similar conditions to the other mixtures and therefor renders "black-body" correction practically the sam throughout.

The delicacy of a method of this sort is seen by referrin to curves describing growth of intensity as compared wit growth of temperature. Thus in the red, Le Chatelie gives the following comparisons:—

°C.	Intensity at 0563 wave length.
900	1·0
1000	3·9
1100	12·0
1200	32·0
1300	81·0
1400	165·0
1500	325·0
1600	624·0
1700	1120·0

His remarks as to black body corrections may b quoted. "The variations of radiation with temperatur are sufficiently marked so that the errors committed i neglecting the emissive power are small. Except fo bodies exceptionally white the emissive powers at higl temperatures are superior to 0·5. By taking them equa to 0·75 the greates errors between 1000° and 1500° wil be from 25° to 50°."

In recording radiation intensities for manufacturing purposes, an absorption plate, ruled with strips of gradatec densities, is placed in front of a sensitive plate in a repeating back, and successive strips crossing the absorp tion strips are exposed to the radiation from the firing tube as used in spectroscopic observations, caps of known calculated temperatures being used to standardise each plate, the number of strips through which different inten sities of radiation will pass being noted by examination o the negative by reflected light.

If only a small amount of work is to be done, the Chapman-Jones plate tester is perfectly satisfactory, but care should be taken to develop the plates used in com parison with each other in the same dish. As a matter of detail ferrous oxalate is invariably used for this work.

The differences of effect are of a large order and amply suffice to differentiate radiation intensity, which, in its turn, is referred to temperature of combustion.

The value of this method of observation lies in elimination of personal error and in the non-disturbance of results by the effect of variations of quantity. Only such a portion of the contents of the firing tube is permitted to radiate upon the photographic plate as corresponds to the minimum quantity cap, and thus the portion of the tube employed is always saturated with incandescent matter. The comparison by this and the spectroscopic tests of caps G and H is interesting, for H contains twice the quantity of the same mixture as G, but only produces equal radiation effect.

In practice a 2 in. length of the tube is left bare, and with a rapid plate like the Ilford Monarch good readings are obtained with the Chapman-Jones plate-tester at a distance of 6 ins.

With mixtures made with reasonable care, and which give calculated gas production and comparative agreement as to total heat, the knowledge gained by the spectroscopic or photographic method as to temperatures furnishes a further proof that theory is not being unduly strained when an endeavour is made to argue from composition to characteristics and thence to ballistics. But if this is so, so far as ultimate results are concerned, regularity and rapidity of action must always be determined experimentally, for physical conditions and exact degree of dryness largely influence these factors.

As referred to later, varnish and coating materials modify the behaviour of the main composition, and therefore experimental determinations must always run side by side with calculated results.

From a practical point of view the influence of temperature *qua* temperature upon ignition is of the utmost importance, especially at or near the limiting temperatures

* For full description of the Féry absorption pyrometer, see "High Temperature Measurements," Le Chatelier, 1904, page 227. For description of instrument and discussion of accuracy of standard light used in this instrument, see "Optical Pyrometry," page 221 (Waidner & Burgess, Bull. No. 2, Bureau of Standards, Washington).

† That is to say:—Practically the diameter of 12-bore cartridge case.

between which the standardisation of present-day powders has been effected. What the future may have in store in the way of explosives demanding a low or high temperature igniter is another question altogether, but with existing explosives, defective and sluggish ignition is always to be feared, especially in cold weather with low temperature ignition, and too rapid ignition if temperature of igniter be above the upper limit. Heat interchange, then, becomes so rapid and local that "jar" or shock is produced, and in a shot gun this is made manifest by the production of "balling" of the shot. Observations over a long period of years have shown what a fertile source of "balling" too high a temperature of ignition may be, and the explosive appears to be acted upon so locally that the effect is not necessarily shown up in enhanced chamber pressures.

In dealing with the relation of ignition characteristics to ballastics, the deductions drawn must necessarily be on broad lines, which are justified not only by special trials but by experience over a long period of years and under varied conditions of loading, climate and so forth.

Table I. gives ballistics obtained with Mark I. Cordite 31·85 grs. and 215 gr. bullet with caps F,G,K,L, which differ widely in their characteristics.

The latitude of action of this particular explosive is very marked in this series of trials, and whilst there is a small advantage obtained either with increased temperature or rapidity of discharge of the igniting substance, the differences are too small to permit sound deductions being drawn beyond this—that it is highly satisfactory for a service explosive to be as independent of its igniter as it has proved to be within the limits of these trials.

Table II. deals with another nitroglycerin and nitrocellulose explosive, and reveals a somewhat different condition of things, not perhaps quite unexpected from the lower temperature of combustion and the more fibrous character and larger initial surface of this explosive as compared with Mark I. cordite.

The caps used for this series were F, G, K, L, M, described in Table IV.

F is an example of per-oxidation, moderately high temperature and large ratio of gases to solids. G and K are typical of hypo-oxidation, low temperature and lower ratio of gases to solids. L and M of complete combustion when the aluminium coating is not taken into account, but of hypo-oxidation and high temperature and smaller ratio of gases to solids when the aluminium enters the reaction.

These results indicate that the low energy cap G gives the best ratio of velocities to pressures compared with K and L. On the other hand, the experimental igniter M, which carries much higher heat units per unit volume, gave practically the same ratio of velocity and pressure but higher intrinsic numbers.

Whether the use of an igniter whose calculated temperature of combustion may rise as high as 4000° C. is desirable under conditions of tropical storage and use is quite an open question, but it marks a new departure and is worthy of serious investigation. It is found to yield a maximum of heat units, temperature and percentage of solids, to obtain which the high temperature of combustion of metallic aluminium has been taken advantage of, the composition being coated with powdered aluminium more or less insulated by means of varnish.

The degree of insulation of the metallic coating from the main composition (as this cap is at present made) appears to control the amount of aluminium which enters into the reaction and to this the difference between L and M is probably to be ascribed.

As shown in Table II., the ballistic results obtained with F and K ignition are apparently anomalous. The energy test shows little difference, yet K produces more pressure than F. Total heat of F is larger than with K, but velocities of K are higher. These results are ascribed to larger flash-holes in the case of F, causing a more local application of heat to the explosive than is the case with small flash-holes in K and the consequent high-pressure jets effecting a more perfect distribution of ignition material.

In Table III. the external and internal ballistics in the 12-bore sporting gun are set forth, in conjunction with caps A, B, C, D, E, L and powders 1, 2, 3. The powd are all three of the fibro-colloidal class, that is to say, t they are not completely gelatinised, Powder II. be more gelatinised than Powder I. Powder III is, ev with the most suitable igniter, near the bottom limits efficiency and well illustrates what happens with such explosive and a weak cap. In this series of trials t charges of powder and shot, also the method of waddi are those usually regarded as standards for the particu powders and calibre of arm. The results are set out terms of velocity over 20 yards (V), pressure at 1 in. fr breech (P), recoil expressed in feet per second veloci of recoil imparted to a 7 lb. gun (R); Time elapsi between striking of cap and exit of shot from muzzle (T (In this last connection it may be noted that a time (of more than 0·006 second indicates slow ignition, at 0·0 second the hesitation is noticeable without instrumen at 0·015 second the "hang-fire" is marked.) (D) Patte is 30 in. circle at 40 yards from a 28 in. barrel of modifi choke boring.

With Cap D and Powders I and II the hesitation distinct, though Powder II is less sensitive than Powder to the bad effect of the weak cap.

On the upper limit, Powder II develops less pressu than I with a rapid cap, and would thus appear to posse greater latitude of action.

Connoting Tables III. and IV. it would appear that tot heat units in the igniter influence velocity, but that tem perature is an important factor in determining time ignition provided a sufficient quantity of heat is al present.

With Cap A[4] and Powder II the effect of rapidity ejection of the igniter, though at a low temperature, marked in its power to produce short time of ignition bu with enhanced pressure and no gain in velocity.

Caps A, B and C may be regarded as satisfactory pr ductions, yet they are of entirely different types, and larger quantity of material is used in B to obtain th necessary heat and gas production. It will be note that B contains a mixture yielding a higher proportio of solids than A, develops a lower temperature, and i more progressive in its action as evidenced by the energ test. The reaction of B does not reach complete com bustion, the oxygen present being insufficient to oxidis all the carbon of the fulminate to CO_2 or to attack all th sulphide of antimony, the unoxidised residue of whic can be found in the products of combustion.

Cap A is an excellent and typical example of a mixtur calculated for reactions involving per-oxidation, it is mor gaseous in its products, produces a higher energy and higher temperature than B, a smaller charge is therefor required, *viz.*, 0·027 grm., including the tinfoil, as com pared with 0·0481 grm. in B.

Whether the presence of free oxygen in the gaseous pro ducts has any influence upon ignition is at present an oper question, though on theoretical grounds the applicatio to an explosive of an oxidising flame instead of a reducin one would appear to involve a greater certainty and regularity of ignition, but, as stated above, data are wanting on this point. Apart from this, experience o the varying conditions of sporting ammunition employ ment has shown that the chances of regularity are bette with a composition calculated for complete combustion.

Cap C is particularly interesting as involving peroxi dation and large percentage of solids, also as consti tuting a departure from ordinary practice in that it con tains neither mercury fulminate nor antimony sulphide, but consists of a mixture of potassium chlorate and sulphocyanide of lead, though not in the most advan tageous proportion, there being present a large excess of chlorate, which produces free oxygen but to an unnecessary extent, unless the cap were coated (as it is not) with tinfoil to react with the free oxygen and so increase not only temperature but also percentage of solid products. The advantages of a mixture which only contains two constituents make this type worthy of further study.

The inferences from A, B and C are that total heat may vary from 10 to 17 grm. calories, total gas not exceeding 5 c.c. including mercury vapour; rapidity differences shown by energy test, if of a fairly large order, do undoubtedly show up in chamber pressures, but with

semi-colloidal powders gas volume of igniter is an important factor in pressure production. The comparison of A with A^3 and A^4 in Tables III. and IV., illustrate this point.

For powders of the semi-colloidal type, as at present standardised, the upper limit of temperature of igniter, calculated by Le Chatelier and Mallard's formula, is placed at 3200° C., beyond which heat transfer becomes so rapid as to cause jar and shock and frequently "balling" of shot.

Cap D is of a type now happily nearly obsolete, it contains powdered glass, variable quantities of sulphur and mercury fulminate, and the quantity of charge is insufficient to produce necessary total heat units, whilst on the other hand its rapidity of action and high percentage of gaseous products prevent an increased charge being used.

Cap E is an empirical imitation of B, and is another example of a reaction only extending to hypo-oxidation. It was supposed that with reduced charges of powder and shot in a cartridge case reduced in length advantage would be gained as compared with A. But in practice this is not realised, with Powder I there is practically no difference, whilst with Powder II there is actually a loss of velocity produced by E as compared with A. Experience with reduced charges leads to the conclusion that the maximum igniter is required to overcome the effect of reduced resistance and so arrive at the proper chamber pressure associated with perfect combustion.

Cap E was originally intended for use with a completely gelatinised explosive of small granulation, it having been found that with ordinary caps of that period, bad hang fires occurred, and the expedient was adopted of making the flash-hole sufficiently large to allow a few granules to pass through and remain in actual contact with the composition, and so give the explosive the advantage of the highest temperature available from the igniter. But it has since been found in practice that an igniter of higher temperature of combustion in a chamber with ordinary flash-hole which does not make special provision for the granules to sit in contact with the composition answers equally well. The inference as to the value of temperature, *qua* temperature in certain cases, especially with powders in which gelatinisation has been carried to a considerable extent, is obvious.

Cap J is a most excellent example of careless manufacture, the charge is deficient in quantity; the percentage of fulminate of mercury varies from 29·5 to 36·53 per cent.; the antimony sulphide from 8·93 to 19·00 per cent.; powdered glass from 8·09 to 16·62 per cent.; potassium chlorate from 30·34 to 50·05 per cent.; varnish from 1·15 per cent. to 4·76.

One remarkable feature of this cap is that on very slight heating it practically loses its explosive qualities, though individual caps behave in this respect to a different degree, and the explanation appears to lie in the quantity and nature of the varnish material which, on warming, soaks into the composition and isolates the components from each other. The ballistic results were characterised by extreme irregularity.

The effect of varnish is always a factor to be reckoned with, and as leading to divergence from calculated results. The influence of small proportions of carbonaceous materials such as resin, paraffin, vaseline, in modifying the action of explosives, is well known and cap composition is not exempt from such influence.

The material used to coat the composition, partly to protect it against moisture, and partly to prevent undue sensitiveness, and possibility of explosion *en masse* if caps are in transit or during handling, is of equal importance with, and in some ways of greater importance than, the varnish. Various materials are in use for the purpose, tinfoil (frequently containing large percentages of lead) paper, chlorated paper, varnished paper and recently powdered aluminium. The nature of the coating material is set forth in Table IV., and it will be observed that A is tin-foiled, whilst A^1, A^2, A^3, and A^4 are not. The ballistic results of Table III. and cap tests and characteristics of Table IV. show the ultimate effect of the foil, and amongst other data attention is called to the fact that A^2 compared with A contains a 25 per cent. increase of charge, and then does not produce such good ballistics as does Cap A when its charge is increased 12 per cent. by an addition of foil.

In the case of powdered aluminium being employed as coating agent, the effect on the reaction is still greater, for aluminium does not even demand free oxygen, but is able to exercise a preference over either carbon monoxide, or antimony sulphide, or both, replacing the moderate calories of combustion yielded by these compounds, by its own very large heat production.

Aluminium can react even with antimony sulphide, the substitution involving a net gain of 92 kilo calories for the molecular reaction—

$$Al_2 + Sb_2S_3 = Sb_2 + Al_2S_3.$$

A similar reaction between aluminuim and antimony sesquioxide produces 162 kilo calories..

The difficulty of stating what reactions really do take place with energetic materials renders experimental knowledge of comparative temperatures absolutely essential.

The molecular gramme-calories of tin burning in oxygen are 141,300, those of aluminium being 393,000, but this means that the stannic oxide formed carries 941 grm. calories per grm. and the alumina, 3,853. Comparing these grm.-calories per grm. with those given in Table IV. for the various compositions, it is at once evident that, starting with compositions ordinarily giving some 500 grm. calories per grm., the addition of materials which can add respectively 941 and 3853 must be large in effect even when the addition is comparatively small in amount.

The bearing on temperature is seen in Table IV., in the comparison of A and A^1, A^2, A^3, A^4, but it may be here remarked that the low specific heats per unit weight of stannic oxide and alumina, compared with those of carbon dioxide and oxygen, are an additional influence upon temperature increments.

On the other hand, if, as in Cap B, there is no free oxygen present, the tinfoil coating is blown away and simply adds to the fouling.

In sporting guns the presence of a tin-fouling is not a very serious matter; but in small-bore rifles a fouling of this sort is particularly objectionable, therefore, if caps intended for use in small-bore rifles must be foiled to comply with regulations of safety, their composition should always be such as will burn the tin to stannic oxide.

Other influences, such as aggregation of the particles and the proper incorporation of the mixture, must not be disregarded. Cap A^4 deals with this question in Table IV. In addition to these the thickness and elasticity of metal of cap shell, the area of percussion, the position and area of flash-holes, and the blow used for percussion must be continually kept in mind. The practical conclusion to which a careful examination of the tables leads, is that whilst with carefully-manufactured explosives there is considerable latitude of action, yet it is in apparently small details that the conditions of highest excellence are to be found; the extent of the industry involved (to say nothing of the public service) and the interest attaching to investigations of the sort render the subject not unworthy of attention, this communication is, therefore, offered as a record of progress and state of knowledge.

Acknowledgment is gratefully made to the Superintendent and officials of the Royal Laboratory, Woolwich, for the use of a pyrometer in the early stages of the investigations; to Messrs. F. W. Jones and H. Melville Smith, for a supply of carefully-prepared materials; and to Mr. H. Frodsham for valued help throughout.

Discussion.

Lieut.-Colonel Sir Hilaro Barlow said he was pleased to hear that cordite could be ignited with caps that apparently gave a large or small solid residue. Whether the modified cordite, when it came in for small arms, would do as well he could not say. Of course, a reduction from 57 per cent. of nitro-glycerine to 30 per cent. must make a considerable difference in the nature of the explosive. Naturally, with a larger portion of nitro-cellulose it would be of a harder and more horny nature. Turning to the question of ignition in the rifle, of which he knew something, as he had recently carried out an investigation for the Small Arms Committee in connection with what were called wide shots in the sighting of rifles, every individual Government ·303 rifle, before it went into service, was shot to test its sighting by the inspection branch, and each rifle had to put every one of a series of five shots into a rectangle of about 1 in. by 1½ ins. at a range of 100 ft. For some extraordinary reason a bullet would occasionally strike half an inch or more to one side or below. Assuming the velocities in a series of rounds varied by 100 f.s.—say, between 2100 and 2000 f.s.—which, it might be added, would mean exceedingly bad regularity, as the extreme variation rarely exceeded 50 f.s., while the mean variation was generally about 6 f.s., and the specification laid down that it should be less than 10. Anyone could calculate that a difference of even 100 f.s. at a 100 ft. ought not to make a difference in the point of impact, up or down, of more than one-tenth of an inch; he thought it would be rather less. But they got these errors of half an inch, and so on, and they had large and expensive trials, to try and ascertain the cause of them. In that investigation one of the first points to determine was the regularity of the ignition. It was interesting to find from Mr. Borland's statement that the question of cap composition made such extraordinarily little difference in the velocity, as it bore out his own results. Judging from the experience with cordite in big guns, one could do not do better for the purpose of an experiment, which needed an absolutely unimpeachable ammunition, than use a black powder priming, of course quite irrespective of subsequently introducing it as a service arrangement. He used 1 grain of black powder done up in a little muslin bag to make sure of the ignition, and obtained some very good results, but, he regretted to say, nothing better than he had obtained with the ordinary service cap. Of course the service composition, as they probably knew, was potassium chlorate 14 parts; antimony sulphide, 18; mercury fulminate, 8; sulphur, 1; meal powder 1; and he thought it was the presence of the meal powder which helped to make it a good composition. The best series of velocities obtained with the service cap in 10 rounds, as compared with those he obtained using black powder ignition, *viz.*, 2016, 2007, 2009, 2002, 2012, 2008, 2008, 2009, 2007, 2010 f.s.; mean observed velocity, 2009; greatest difference 9 f.s.; mean difference only 1·96 f.s.; such results were satisfactory, but more often a mean difference of six and a greatest difference of about 46 resulted. The following figures given by 20 rounds were obtained by using black powder priming:—2030, 2030, 2032, 2029, 2054, 2052, 2055, 2025, 2025, 2023, 2023, 2047, 2024, 2024, 2023, 2039, 2040, 2036, 2020, 2037. These values could be divided into some interesting groups, thus:—the first four rounds showed a mean observed velocity of 2031, the greatest difference 4, and the mean difference 1·5, which was extremely good. Then they suddenly rose from 2029 to 2054, which he did not pretend to explain, thus: 2054, 2052, 2055, and a mean difference of 1·1. Next a series of four occurred again, 2025, 2025, 2023, 2023, with a mean difference of 1; then a rise up to a single round giving 2047, and then another group of rounds much lower and so on. He mentioned this because it was suggestive; he could, however, offer no explanation. If other people could be more successful than he had been in ascertaining the causes of these remarkable variations nobody would be more delighted than he himself, and he presumed the Government would soon hear of it, and be glad to do so. Another curious feature in connection with this investigation, which he was sure of, was that in small arms the accuracy at 500 yards and longer ranges, and the regularity of velocity and accuracy at 100 ft., in no sense went together. That, again, was an extraordinary fact which he could not explain, though he had spent the last two years in trying to do so. It was the result of firing between 300 and 400 targets of 20 rounds each, one of the biggest investigations on the subject ever made. Until the "Palma Trophy" ammunition came in (and he must couple that with the King's Norton Company) the ·303 rifle was distanced by the Mannlicher and Mauser rifles. The Mannlicher and Mauser did shoot slightly better at 900 yards, and markedly better at 1000 yards, but it is equally the fact that they shot markedly worse from the point of view of regularity of velocity and patterns on a target at 100 ft. than our own rifle did. The probable explanation was that with the larger charges the King's Norton Company put into the "Palma Trophy" ammunition, and, with the higher pressures resulting, there was little doubt the bullet was better expanded, and thus the increased accuracy resulted. Although this seemed very simple now, it was a great move, and had brought the ·303 rifle up in a wonderful way.

Mr. Walter F. Reid said caps had many years ago been tested in a simple way by using black powder; but, in developing smokeless powder, they were confronted with the curious fact that they did not get the same results with similar charges of powders which were perfectly uniform in composition. Mr. Borland assisted him in some of those researches. It was true that at that time their methods were very primitive, and, as they were perhaps the first carried out in practice, they might be of interest. The cartridge case, with the cap in it, was fixed in a tube which was inserted into the gun or an apparatus with a striker similar to a gun. A certain portion of the tube was cut open and wires crossed it; at regular intervals on each wire a strand of guncotton was fixed. The number of strands that were ignited by the flash was supposed to be a measure of the force of the cap. Great differences were found in the strength of the caps. A Belgian firm then introduced caps which secured complete ignition; but sometimes it was too much for the gun, and there were many accidents. There was one kind of cap which burst a good many guns, which, of course, was attributed to the powder, although their experiments showed that the powder could not have been properly ignited. He was glad to see that Mr. Borland had been carrying out such experiments in a somewhat different way. Whilst not criticising the method he had adopted of using the spectroscope, he did not quite see the connection between the spectroscopic action and the ignition of the explosive. Again, there was a slight source of error in the use of the glass tube, because there was a very dense precipitate on that tube; the particles were projected against its side, and from the commencement of the flash there must be a diminution in the light which was transmitted. That error would depend to some extent on the composition of the cap which was flashed. Personally, he preferred the method of photographing the flash of the cap in the open air. With regard to the question of the regularity of ignition of cordite, he thought that was due to a general principle which he found out many years ago by actual tests, and which still held good. That principle was that when a compound substance of this kind was ignited, the sensitiveness of the substance was regulated by the sensitiveness of the most sensitive ingredient in it. In cordite there were two explosives, nitro-cellulose in the gelatinised form and nitro-glycerine. The latter being highly sensitive, he thought the sensitiveness to ignition was due to the presence and proportion of nitro-glycerine, and therefore with practically any cap a fairly good ignition could be obtained. That principle was found out also in a practical way when he first placed gelatinised smokeless powder on the market. For the E C powder some sportsmen recommended putting a pinch of black powder in the cartridge case.

Some points Mr. Borland had not alluded to exercised an important effect on the ignition of the charge from the cap. There was a diagram on the wall showing an anvil with rather a sharp point. The striker of the gun did not

invariably in practice, although theoretically it ought to do so, strike upon that point. The charge in the cap might not, therefore, be placed exactly between the point of the anvil and the point of the striker, and any deviation, however small, to the right or left, would alter the force of ignition, and consequently of the explosion. Again, different compositions used differed in their cohesion, so that a regular or irregular detonation depended on the amount of cohesion in the cap. Another point was the metal of which the cap was composed. Copper was an extremely good conductor of heat, and if it were used part of that heat, which should be produced quickly and in a concentrated form, was lost. A better result would be obtained when the cover of the cap was made of a badly-conducting material. The same with the tinfoil cover; it was difficult to imagine a worse substance; it acted as a sort of cushion for the percussive striker. The varnishing was a weak point, for, as Mr. Borland had pointed out, according to the amount of varnish which penetrated the mass, so was the initial explosion modified. Another matter which should be mentioned was the amount that passed through the flash-hole—the channel through which the initial explosion reached the bulk of the charge. That ought to be, not a uniform flash-hole in all cases, but proportional, not only to the contents of the cap, but also to the explosive. In sporting ammunition especially a source of many miss-fires was the loading or re-loading of the cartridge, and in the way in which the operation was carried out there was no certainty that the anvil was in exactly the same relative position in each case. If a means could be devised for fixing the anvil and cap together and placing them into the chamber, it would be much preferable to the present system. With military caps the danger was not so great. They were now coming to a totally different method of cap manufacture, namely, the wet process. Formerly, the composition was sifted in in a dry state, now it was in a wet state, and the fulminate of mercury did not become dry until it was in the cap.

Mr. W. Macnab said any information which could be given as to the nature of the ingredients used, either in the caps or detonators and their behaviour, was of the greatest importance.

Dr. O. Silberrad asked the author if he had done any work on the measurement of the pyrometric value of the products of combustion, based on the contraction they underwent in cooling from their maximum temperature. This field of research seemed to be of especial interest in the light of Sir Andrew Noble's recent experiments on propellants, carried out on these lines. In these experiments it was shown that the pyrometric value of cordite M.D. approached more nearly to 4220° C. than 2320, as calculated from the present accepted specific heats. Regarded from a similar standpoint, therefore, should not the figures given by the author read 5500, &c., more nearly than 3050, &c., in degrees centigrade as based on the air thermometer? The author's figures would, however, still be strictly comparative, and as such of great interest and value. In reference to the method of estimating mercury some work, recently published by the American Bureau of Technology, tended to show that even on firing a rifle, in the ordinary manner, sufficient mercury remained behind in the cartridge case to cause serious deterioration of the metal when the caps used contained fulminate. In the light of this, did it not seem possible that greater precautions were necessary in carrying out the estimation?

He would also like to refer to the work of Mettegang and Bichel on the determination of the absolute velocity of detonation, reported at the Fifth Congress of Applied Chemistry in Berlin. The method used by these investigators depended upon the consecutive interruption of two wires carrying a divided current running through the two ends of a long cartridge, and subsequently through the secondary coil of an induction coil, the sparks produced on the rupture of the wire being recorded on a revolving drum. In the case of gelatine dynamite the velocity recorded approached 4½ miles per second (6915 m). In this connection he would point out that interesting information might result from a comparison of the author's figures on the time of ignition required by any specific cap composition with its absolute velocity of detonation.

Mr. R. J. Friswell said he was perfectly satisfied, after seeing the experiments, that the spectroscopic method was really a valid one for estimating temperatures.

Numbers were given on the table showing the cubic centimetres of gas per cap, but it would be interesting to know whether the volume was calculated at 0° and 760 mm., or by the Le Chatelier formula, or at the temperature as observed by the radiation intensity of the lamp. If they were calculated at either of the latter temperatures they must be from five to ten times the volume shown on the table; and it was possible that some relation would be established with the numbers given as the energy test in lbs. One other point to which the author had alluded was the question of the area of percussion. He investigated this some time ago, being led to it by some experiments as to the cause of the local explosion of liquid films under percussion, and he began to consider the question whether the effect on the cartridge might be accounted for by the position of the anvil; because, if the striker was not absolutely central, as Mr. Reid had pointed out, very different results would follow when the striker hit the cap. In the case of the ogival-headed anvil a blow striking at an angle might occur which would cover a considerable area on the side of the anvil, or a blow might fall exactly on the edge; whether one or the other occurred depended entirely on the position the anvil occupied, which, of course, was not determinable when the cartridge was placed in the gun. In his experiments he reversed things. He took a large anvil and inverted the cap, using the striker on the inside thereof. He then proceeded to reduce the striker in size, and kept on filing it down until it became a point. He thus succeeded at last in bringing about a state of affairs in which the striker could be driven through the cap without causing an explosion. Before reaching that there was a stage at which, when the striker was driven in, a slight sputtering took place at the point, which did not extend to the rest of the composition, and before that there was another stage at which the striker started a slight combustion at the point of impact which slightly extended and then caused the contents of the cap to be projected in a mass upwards. He concluded from these experiments that great importance was to be attached to the area of percussion, to which is due the amount of initial explosion in the cap.

Mr. Thorne said the point mentioned by Mr. Reid, as to the question of miss-fires and hang-fires, had received a good deal of attention from the Gun Makers' Association. Attempts were being made to standardise the relation between the gun chamber, the cartridge case, the anvil and the striker.

Mr. H. Melville Smith said that with Mark 1 cordite it did not matter whether the hammer struck the middle of the anvil or its side; the results were practically the same, as the cap was driven down on the anvil. Again, with regard to the shape of the striker—with fuses and small munitions the strikers were made as pointed as possible and finished on an oil stone so as to make sure of absolutely good ignition; this went to prove that shape of anvil differed greatly under various circumstances. The sporting cartridges certainly seemed to show that with such a large number of different powders it was almost impossible to make a universal cap. This was a matter of some moment as the Gun Makers' Association were proposing a standard. He feared there was trouble ahead for anyone who standardised.

Dr. H. W. Brownsdon asked if Mr. Borland had made any analytical examination of the solid products of combustion. He had been surprised to find compositions containing more chlorate than was required for the complete combustion of the fulminate and stibnite, according to generally-accepted equations, yield a certain amount of sulphide in the solid products of combustion. The question was, how had the oxygen of the chlorate divided itself up amongst the various products of combustion, and if, as certainly was the case, some sulphide escaped oxidation, it seemed to him very probable that

Discussion.

Lieut.-Colonel Sir Hilaro Barlow said he was pleased to hear that cordite could be ignited with caps that apparently gave a large or small solid residue. Whether the modified cordite, when it came in for small arms, would do as well he could not say. Of course, a reduction from 57 per cent. of nitro-glycerine to 30 per cent. must make a considerable difference in the nature of the explosive. Naturally, with a larger portion of nitro-cellulose it would be of a harder and more horny nature. Turning to the question of ignition in the rifle, of which he knew something, as he had recently carried out an investigation for the Small Arms Committee in connection with what were called wide shots in the sighting of rifles, every individual Government ·303 rifle, before it went into service, was shot to test its sighting by the inspection branch, and each rifle had to put every one of a series of five shots into a rectangle of about 1 in. by 1½ ins. at a range of 100 ft. For some extraordinary reason a bullet would occasionally strike half an inch or more to one side or below. Assuming the velocities in a series of rounds varied by 100 f.s.—say, between 2100 and 2000 f.s.—which, it might be added, would mean exceedingly bad regularity, as the extreme variation rarely exceeded 50 f.s., while the mean variation was generally about 6 f.s., and the specification laid down that it should be less than 10. Anyone could calculate that a difference of even 100 f.s. at a 100 ft. ought not to make a difference in the point of impact, up or down, of more than one-tenth of an inch; he thought it would be rather less. But they got these errors of half an inch, and so on, and they had large and expensive trials, to try and ascertain the cause of them. In that investigation one of the first points to determine was the regularity of the ignition. It was interesting to find from Mr. Borland's statement that the question of cap composition made such extraordinarily little difference in the velocity, as it bore out his own results. Judging from the experience with cordite in big guns, one could do not do better for the purpose of an experiment, which needed an absolutely unimpeachable ammunition, than use a black powder priming, of course quite irrespective of subsequently introducing it as a service arrangement. He used 1 grain of black powder done up in a little muslin bag to make sure of the ignition, and obtained some very good results, but, he regretted to say, nothing better than he had obtained with the ordinary service cap. Of course the service composition, as they probably knew, was potassium chlorate 14 parts; antimony sulphide, 18; mercury fulminate, 8; sulphur, 1; meal powder 1; and he thought it was the presence of the meal powder which helped to make it a good composition. The best series of velocities obtained with the service cap in 10 rounds, as compared with those he obtained using black powder ignition, *viz.*, 2016, 2007, 2009, 2002, 2012, 2008, 2008, 2009, 2007, 2010 f.s.; mean observed velocity, 2009; greatest difference 9 f.s.; mean difference only 1·96 f.s.; such results were satisfactory, but more often a mean difference of six and a greatest difference of about 46 resulted. The following figures given by 20 rounds were obtained by using black powder priming:—2030, 2030, 2032, 2029, 2054, 2052, 2055, 2025, 2025, 2023, 2023, 2047, 2024, 2024, 2023, 2039, 2040, 2036, 2020, 2037. These values could be divided into some interesting groups, thus:—the first four rounds showed a mean observed velocity of 2031, the greatest difference 4, and the mean difference 1·5, which was extremely good. Then they suddenly rose from 2029 to 2054, which he did not pretend to explain, thus: 2054, 2052, 2055, and a mean difference of 1·1. Next a series of four occurred again, 2025, 2025, 2023, 2023, with a mean difference of 1; then a rise up to a single round giving 2047, and then another group of rounds much lower and so on. He mentioned this because it was suggestive; he could, however, offer no explanation. If other people could be more successful than he had been in ascertaining the causes of these remarkable variations nobody would be more delighted than he himself, and he presumed the Government would soon hear of it, and be glad to do so. Another curious feature in connection with this investigation, which he was sure of, was that in small arms the accuracy at 500 yards and longer ranges, and the regularity of velocity and accuracy at 100 ft., in no sense went together. That, again, was an extraordinary fact which he could not explain, though he had spent the last two years in trying to do so. It was the result of firing between 300 and 400 targets of 20 rounds each, one of the biggest investigations on the subject ever made. Until the "Palma Trophy" ammunition came in (and he must couple that with the King's Norton Company) the ·303 rifle was distanced by the Mannlicher and Mauser rifles. The Mannlicher and Mauser did shoot slightly better at 900 yards, and markedly better at 1000 yards, but it is equally the fact that they shot markedly worse from the point of view of regularity of velocity and patterns on a target at 100 ft. than our own rifle did. The probable explanation was that with the larger charges the King's Norton Company put into the "Palma Trophy" ammunition, and, with the higher pressures resulting, there was little doubt the bullet was better expanded, and thus the increased accuracy resulted. Although this seemed very simple now, it was a great move, and had brought the ·303 rifle up in a wonderful way.

Mr. Walter F. Reid said caps had many years ago been tested in a simple way by using black powder; but, in developing smokeless powder, they were confronted with the curious fact that they did not get the same results with similar charges of powders which were perfectly uniform in composition. Mr. Borland assisted him in some of those researches. It was true that at that time their methods were very primitive, and, as they were perhaps the first carried out in practice, they might be of interest. The cartridge case, with the cap in it, was fixed in a tube which was inserted into the gun or an apparatus with a striker similar to a gun. A certain portion of the tube was cut open and wires crossed it; at regular intervals on each wire a strand of guncotton was fixed. The number of strands that were ignited by the flash was supposed to be a measure of the force of the cap. Great differences were found in the strength of the caps. A Belgian firm then introduced caps which secured complete ignition; but sometimes it was too much for the gun, and there were many accidents. There was one kind of cap which burst a good many guns, which, of course, was attributed to the powder, although their experiments showed that the powder could not have been properly ignited. He was glad to see that Mr. Borland had been carrying out such experiments in a somewhat different way. Whilst not criticising the method he had adopted of using the spectroscope, he did not quite see the connection between the spectroscopic action and the ignition of the explosive. Again, there was a slight source of error in the use of the glass tube, because there was a very dense precipitate on that tube; the particles were projected against its side, and from the commencement of the flash there must be a diminution in the light which was transmitted. That error would depend to some extent on the composition of the cap which was flashed. Personally, he preferred the method of photographing the flash of the cap in the open air. With regard to the question of the regularity of ignition of cordite, he thought that was due to a general principle which he found out many years ago by actual tests, and which still held good. That principle was that when a compound substance of this kind was ignited, the sensitiveness of the substance was regulated by the sensitiveness of the most sensitive ingredient in it. In cordite there were two explosives, nitro-cellulose in the gelatinised form and nitro-glycerine. The latter being highly sensitive, he thought the sensitiveness to ignition was due to the presence and proportion of nitro-glycerine, and therefore with practically any cap a fairly good ignition could be obtained. That principle was found out also in a practical way when he first placed gelatinised smokeless powder on the market. For the E C powder some sportsmen recommended putting a pinch of black powder in the cartridge case.

Some points Mr. Borland had not alluded to exercised an important effect on the ignition of the charge from the cap. There was a diagram on the wall showing an anvil with rather a sharp point. The striker of the gun did not

means unusual to find 15 per cent. variation, whilst a sample recently examined showed that the charges varied from 0·0370 grm. to 0·0506 grm., *i.e.*, 30 per cent. on the mean weight.

As regards analysis of products this would be interesting if it could be ascertained that no secondary reactions took place as cooling progressed; but the igniter does its work at a high temperature and in the hot atmosphere produced in the cartridge when the first particle of igniter emitted meets the explosive. But, unfortunately for value of analysis of products, this condition does not exist when the cap is fired in a cold closed vessel.

Mr. Guttmann's observations as to the effect of admixture of the cap ingredients was borne out by the author's experience with A^4, referred to in the paper. The exact percentage of moisture also exercised a controlling influence upon rapidity, as the author had frequently found after drying samples of unfoiled and unvarnished caps to constant weight, and subjecting them to the crusher test after progressively increasing periods of exposure to the air.

He had carried out various methods for time comparisons, but at present is inclined to attach most importance to the crusher readings, taken in conjunction with knowledge of total heat and gas production as a guide to rapidity of emission of the igniter, and of the instances referred to by Mr. Guttmann, considers F to be more violent in its action than M.

Mr. Axel Carsen wrote as follows:—"I am able to supplement Dr. Silberrad's remarks by explaining that the rate of detonation of a large number of explosives was determined at the Schlebusch Carbonite Works by means of Mettagang's Recorder, an electro-chronograph described in Bichel's 'New Methods of Testing Explosives' (Chas. Griffin and Co., Ltd., London, 1905). During these tests it was found that, apart from the chemical composition and physical character of the various explosives, the velocity of detonation depended to a certain extent upon the diameter of the cartridges, *i.e.*, that up to a certain point the former increased with the latter. Beyond such maximum, which, however, varied for different explosives, the rate of detonation remained constant. A standard diameter of 30 mm. (about 1¼ in.) was ultimately fixed upon.

"In testing fulminate of mercury some considerable difficulty was met with on account of the danger of handling this compound; indeed, it seemed out of the question to work with quantities involved by the diameter adopted for blasting explosives. A diameter of 6·45 mm. (¼ in.) was then used, which gave a velocity of 3920 m. per second, and it was concluded that, with diameters approaching that adopted for other brisant explosives, the rate of detonation of fulminate of mercury would certainly far exceed that measured for any of the latter, *viz.*, some 8000 m. per second.

"In connection with Mr. Borland's 'energy' values, I should like to mention that Bichel applies the rate of detonation to the calculation of the *vis-viva* or percussion force of explosives. Assuming that for all practical purposes the observed rate of detonation equals the velocity of the molecular projection, he adopts the formula

$$\frac{mv^2}{2}$$

in which $m = \frac{weight\ of\ explosive}{981}$, and v = rate of detonation. This method might possibly commend itself to Mr. Borland as a means of checking his results.

"We are all familiar with the various factors which require consideration in standardising smokeless sporting powders to cartridge cases of different make, but for the most part these are merely questions of workmanship. The keynote is in the cap, and exact knowledge of its composition and characteristics derived from tests such as suggested by Mr. Borland presents a valuable guide to manufacturers. Not long ago I had to examine a certain new type of nitrocellulose powder, and I found that when loaded in foreign cases (which were recommended) this powder gave fairly good results. As soon as English cases were substituted, however, there was a marked change; for, whilst still giving 'pleasant shooting' and good patterns, the powder lost considerably in velocity (except up the barrel, where an increase took place), and the pressure went up to a prohibitive figure. This could not, evidently, be traced to position of anvil and firing holes, strike of hammer or case-material, but was due to a change in the cap composition.

"Even in the case of detonators, which usually contain 85 per cent. of fulminate, quality and uniformity play an important part in developing the full potential of mining explosives—a fact which, although recognised, is too often forgotten in passing judgment on their efficiency."

Yorkshire Section.

Meeting held at Leeds, on Monday, February 26th, 1906.

MR. THORP WHITAKER IN THE CHAIR.

AN INVESTIGATION OF THE BARIUM AND CALCIUM SALTS OF GALLIC, PROTOCATECHUIC AND DIGALLIC ACIDS.

BY H. R. PROCTER AND H. G. BENNETT

(Contribution from the Leather Industries Laboratories, University of Leeds).

The following experiments were suggested by a paper on a "New Method for the Analysis of Tannin and Tanning Materials," by Parker and Payne (this J., 1904, page 648). Since its publication this method has been subjected to various criticisms, but it is noteworthy that the discussion has chiefly been in connection with the relative merits of collin and hide-powder, whilst the figure called the "Total Absorptive Value" has escaped attack, and, in view of the fact that it is based upon the formation of a definite metallic compound, has even been hailed as a step in the right direction. It seemed, however, that the evidence given in support of the reliability and significance of these results was inconclusive, and it was considered desirable, therefore, to make some experiments with a view to ascertaining whether the figures obtained in this way were at all consistent and reliable, and if any theoretical significance could be attached to them. To do this it is evidently necessary to experiment at first with bodies of known constitution, and which could be obtained in a sufficiently pure condition, before applying the method to tannins and tanning materials of which the constitution is unknown. Parker and Payne had, to a certain extent, attempted this with gallic and digallic and ellagic acids, but some preliminary experiments showed that their figures required confirmation. Recrystallised gallic acid was therefore chosen for these experiments, along with protocatechuic acid, and also digallic acid as the only tannin about which anything definite is known.

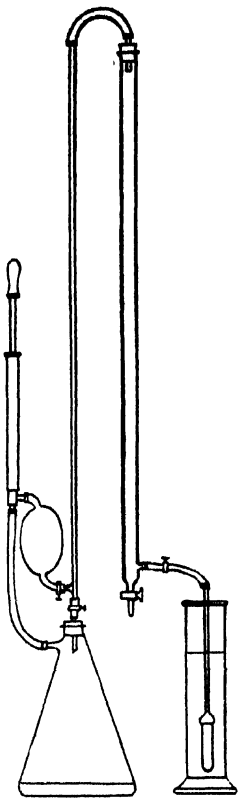
Now it is well known that in alkaline solution both tannic and gallic acids are extremely oxidisable, and, although the products of oxidation are not well investigated, it seemed probable that they were of an acid character, such as to affect the apparent amount of alkali used for neutralisation, and experiment proved this to be the case. Keeping this in mind, the exposure to air involved in ordinary filtration, as used by Parker and Payne, was obviously a probable source of error, and hence efforts were made to eliminate it. This was done in various ways—by working in an atmosphere of coal gas or of petroleum-ether vapour, but preferably by mixing the solutions in the presence of the latter and filtering through a "Berkefeld filter-candle" directly into a self-filling burette, the top of which was connected with a closed apparatus free from oxygen, arranged so that either a partial vacuum or a pressure could be produced in the

burette, as desired. The arrangement of the apparatus is shown in the illustration.

Experiments with baryta.

Baryta was in the first instance experimented with in preference to lime, since it avoided possible complications introduced by the use of sugar in the lime solution, and in absence of oxygen was equally easy to work with.

1. *Gallic acid.*—The first experiments were done with a view to finding whether the precipitate with baryta was completely insoluble, and the gallic acid, therefore, removed entirely from solution. The proportions of Parker and Payne were used, but the quantities halved, *i.e.*, 100 c.c. of N/50 gallic acid (3·76 grms. per litre) and 150 c.c. of approximate N/5 baryta (made by standardising a cold saturated solution), the filtrate obtained through the Berkefeld candle being titrated against a measured quantity, generally 10 c.c., of N/10 hydrochloric acid.



The results obtained in this way were extremely inconsistent and without obvious meaning. Moreover the time of standing before filtration made a considerable difference in the results, thus:—

Hours standing.	Neutralisation value.*
0	24·7
3	25·5
5	26·2
24	32·6

In all these experiments the filtrate, on exposure to air, oxidised rapidly, and deposited a precipitate, mostly dark green, but varying in colour, showing clearly that all the gallic acid had not been precipitated, but that the barium compound was partly soluble even in excess of baryta. Now experiments with gallic, protocatechuic, salicylic and benzoic acids and some phenols, have shown that these bodies become neutral to phenolphthalein and other indicators sensitive to weak acids when sufficient alkali has been added to saturate the carboxyl group; and no precipitate is formed till or near the point at which this saturation is reached, and it is obvious therefore that the precipitate is of a basic character and alkaline to indicators. The soluble part of the precipitate would, therefore, on titration with phenolphthalein and N/10 hydrochloric acid act like free alkali, and hence the figures obtained above are lower than they would be were the precipitate insoluble.

In the calculation of these results, it also became very evident that the large excess of alkali (considered essential by Parker and Payne), being used for the indirect determination of a comparatively small quantity of gallic acid, was a source of error and unreliability, for small differences in the titration obviously correspond to comparatively large variations in the actual neutralisation value of the gallic acid. To get results, therefore, of any reliability and significance, it was necessary not only to lower the excess of baryta used, but also in some way to render the barium precipitate insoluble, and the filtrate unoxidisable. Both these objects were accomplished by the addition of a suitable quantity of alcohol (80 per cent.), which made the precipitate quite insoluble. The next experiments were done with 100 c.c. of gallic acid solution, and 100 c.c. baryta and the solution made up to 250 c.c. with alcohol. The neutralisation values now obtained ranged between 40 and 50, but were still rather variable. This was remedied to some extent by thorough mixing and long standing, three similar experiments showing, after 48 hours' standing, the values 41·9, 41·3, 43·6. It is obvious that the highest figure theoretically possible, assuming that the carboxyl and all three hydroxyls were saturated, would be 40.

Some experiments were now made to illustrate any effect which varying quantities of alcohol might have on the neutralisation value. The same quantities of baryta and acid were used in each case, and the solution

made up to various volumes with alcohol. After standing overnight, the following figures were obtained:—

Total volume.	Neutralisation value.
250 c.c.	43·4
275 c.c.	46·2
300 c.c.	48·6

Hence, although the use of alcohol in moderate quantity is an advantage in completing the precipitation, the use of larger quantities causes the neutralisation value to increase considerably. With the smaller quantity of alcohol, the following results were obtained:—

Total volume, 250 c.c.; 100 c.c. *acid, and* 100 c.c. *baryta solution.*

Experiment.	Neutralisation value.
1	43·6
2	44·0
3	43·5
4	43·4

showing that all the four (OH) groups of gallic acid, both carboxylic and phenolic, are saturated in this case with barium, and that the larger quantities of alcohol probably cause the precipitate to carry down with it, mechanically, some more baryta. To eliminate this co-precipitation, it was found necessary to:—(1) Use a still smaller excess of baryta (150 c.c. acid to 100 c.c. alkali); (2) carry out the precipitation at the water-bath temperature, which also gave a precipitate more coagulated, and therefore easier to filter; (3) add the baryta gradually to the hot mixture of alcohol and acid so that the baryta is never in excess until the precipitation is complete, and then to heat the mixture on the water-bath for 20—30 minutes. By these means the error attributed to co-precipitation was much reduced, and 41·5 was obtained, confirming the figure 40 as representing

* No. of c.c. N/5 alkali absorbed by 100 c.c. of N/50 gallic acid. Each 10 c.c. of N/5 alkali used corresponds, therefore, to one valency either carboxyl or hydroxyl of the gallic acid.

the true neutralisation-value of 100 c.c. N/50 gallic acid. This corresponds to absorption by 1 grm. of dry gallic acid of 125 c.c. N/5 baryta. Parker and Payne give 1 grm. dry gallic acid = 177·75 c.c. N/5 alkali ("Collegium," 1904, p. 267). This figure would correspond to the neutralisation of 5·69 eq. of alkali, by 1 eq. of gallic acid—obviously an impossible result, and presumably a clerical error.

2. *Protocatechuic acid.*—Some experiments were now made with N/50 protocatechuic acid (3·08 grms. per litre) with a view to determining the solubility of its barium precipitate, and also in the hope of confirming the above view of the constitution of these precipitates. It was found, however, that in aqueous solutions, no precipitate was produced, and that although alcohol did produce precipitation it by no means completed it, and that larger quantities of alcohol resulted merely in the baryta being thrown out of solution.

In a similar way, N/5 sugar-lime gave no precipitate with protocatechuic acid, and the addition of alcohol, even in small quantities, resulted in the precipitation of lime. It is by no means certain, though not improbable that free protocatechuic acid exists in natural tanning materials, but in any case it is a derivative of all catechol tannins, and its behaviour may probably be taken as typical.

3. *Digallic acid.*—These experiments were made with a commercial sample of pure gallotannic acid. The moisture was estimated (12 per cent.) at 100° C., and a N/50 solution made up, assuming the rest to be digallic acid (7·318 grms. per litre). If no alcohol was used, the neutralisation values varied between 50 and 60, and increased with standing:—

Stood.	Neutralisation value.
0 hours	49·0
24 ,,	54·3
36 ,,	59·5

As the filtrate oxidised on exposure to air, it was concluded that precipitation was not complete, and hence alcohol was again used. It is, of course, possible that this imperfect precipitation was due to the gallic acid which is present as a constant impurity. The neutralisation values now varied between 60 and 70, and still increased with the time of standing.

The effect of precipitating hot, and of heating was noticed, and after trying various times and conditions it was found that the results converged to a consistent neutralisation value of 76·0 after 1½ hours heating on the water-bath. As also observed with gallic acid, hot precipitation and subsequent heating was an advantage as regards rapid filtration. Concordant results were not obtained under any other conditions.

It was noted that, if the filtration be carried out immediately after precipitation, the results approximate to 60, which would correspond to the saturation of all the six hydroxyl groups of digallic acid; but that if the mixture be allowed to stand or is heated, the value increases. This is best explained on the assumption that the digallic acid is hydrolysed by the action of the baryta, and that 2 mols. of gallic acid being produced, the true neutralisation-value approximates now to 80, the lower number actually found being due to the non-tannin impurities present in the sample; since any gallic acid present would be estimated along with that produced by hydrolysis and would not cause very serious error.

Experiments with N/5 sugar-lime.

1. *Gallic acid.*—Some preliminary experiments with varying excess fully bore out the remarks made in case of baryta as to the unreliability of using large excesses, both on account of co-precipitation and from the magnitude of the error which is involved in small differences in titration.

When no alcohol was used, the filtrate was easily oxidisable on exposure to air, though perhaps to a less extent than in the case of baryta, and hence the addition of alcohol was again tried. The error due to co-precipitation was, however, much more considerable in this case than with baryta, and was perceptible even when the alcohol was diminished to comparatively small quantities, the neutralisation values decreasing with the decrease of alcohol from 50 towards 40.

The actual results are as follows:—

Precipitation hot, and mixture heated half an hour, 150 c.c. of gallic acid solution and 100 c.c. of sugar-lime (N/5).

Added alcohol.	Neutralisation value.
50 c.c.	49·2
40 c.c.	47·9
30 c.c.	46·7
20 c.c.	45·5
10 c.c.	44·1
5 c.c.	13·6
(Precipitation cold and mixture not heated.)	
(Filtered at once.) 50 c.c.	47·0
(After standing two or three days with occasional shaking.) 50 c.c.	49·3
50 c.c. water and no alcohol	42·0

The results confirmed the view that the real neutralisation value is 40, corresponding to the saturation of all hydroxyl groups; but we have not yet succeeded in the case of sugar-lime of eliminating at the same time both the errors of co-precipitation and of solubility.

Some experiments were made using cane-sugar syrup in place of alcohol, in the hope of rendering the precipitate insoluble by virtue of its alcoholic structure, and at the same time abolishing co-precipitation, but the result showed that sugar to have a very peculiar effect on the lime precipitation, changing its colour, bringing a great deal of it into solution, making the filtrate deep yellow and much more easily oxidisable, and rendering the end-point of the titration indefinite. The results showed also a considerable increase in the neutralisation value, which rose to 49·2. What this means is difficult to see, but the sugar evidently introduces another unknown chemical change, and still further complication in the method, and is therefore best avoided altogether. Experiments with sugar-baryta fully bore out the above observations, quite similar effects being observed.

2. *Protocatechuic acid* was not experimented with quantitatively with sugar-lime for similar reasons to those which prevented its titration with baryta (v.s.).

3. *Digallic acid.*—It was thought desirable to confirm the view as to the hydrolysis of digallic acid by alkalis by making a few experiments with sugar-lime in addition to those with baryta. No alcohol was used. The results show neutralisation values of about 50 when the mixture is filtered and titrated at once, and that this increases with time and with heating until the figure reaches 74·8, which is obtained after two hours' heating on the water-bath. This fully bears out the theory that the digallic acid is, as one would expect, hydrolysed by the lime to 2 mols. of gallic acid, and the near agreement between the figures obtained when the reaction is complete for both baryta and lime, is an interesting confirmation of the idea that the discrepancy from the theoretical 80 is due to the impurity of the sample.

Further experiments.

Some experiments have also been made with the tannin of quebracho. An aqueous solution of the partially-purified tannin was made, and by repeated filtration through the candle was made clear.

1. 50 c.c. contained 0·2124 grm. soluble matter. 150 c.c. when mixed with 100 c.c. N/5 sugar-lime gave a reddish-brown precipitate, which was filtered at once with the usual apparatus. The filtrate was deep yellow, and easily oxidisable, with precipitation. The result showed that 100 c.c. of the solution absorbed 21·85 c.c. of N/5 alkali (*i.e.*, 1 grm. dry substance = 51·43 c.c. sugar-lime).

2. The same quantities of tannin and baryta solution were now mixed, and, as it was noticed that the filtrate was as yellow as before, the solution was made up to 300 c.c. with alcohol, and filtered. The filtrate was now decidedly less yellow, but the colour and oxidisability were still present. The result showed 100 c.c. tannin solution = 23·21 c.c. N/5 baryta, *i.e.*, 1 grm. dry substance = 54·21 c.c. N/5 baryta.

3. A further experiment, in which the sugar-lime (100 c.c.) was added to the hot tannin solution (150 c.c.) and

the mixture heated 1¾ hours, showed a considerable increase in its absorptive value. 100 c.c. = 30·97 c.c. N/5 sugar-lime (*i.e.*, 1 grm. tannin = 87·03 c.c. lime). In this case the filtrate was even more yellow than in experiment 1.

These experiments show, we think, that the compounds of quebracho tannin with both lime and baryta are soluble in water, but they are less soluble in water with alcohol added. As this can only be done in case of baryta, it is possible that a series of experiments might determine that particular quantity of alcohol which would make the quebracho-tannin compound with baryta quite insoluble, but it is clear that this quantity must be a greater proportion than any hitherto used, and which would probably cause serious co-precipitation. This it is impossible to examine, but it is conceivable that in presence of quebracho-tannin only the error might be a constant one. If the quantity of alcohol is much increased, baryta is itself thrown out of solution. This is only an illustration of what must happen with the rest of the tannins, the amount of alcohol necessary for complete precipitation will differ in each case; and when determined for every tannin, other errors would have to be made constant by exactitude of manipulation, &c. The last experiment, recorded above, also points very strongly to the hydrolysis or decomposition of the tannin by the alkali, and this opens up the same questions of solubility, &c., which were discussed in connection with digallic acid.

The authors conclude from the above experimental work that the Parker-Payne method in its original form is altogether unreliable and useless. Apart from the unsatisfactory experimental methods, and the obvious liability to error involved in the indirect determination of a small quantity by the use of a large excess of another reagent, it is evident that in these experiments we are dealing with precipitates which are not definite metallic compounds of gallic and digallic acids, &c., but of indefinite constitution and which vary in composition with all variations in methods of working, concentration, temperature, method and order of admixture, &c. Moreover, the method is liable to break down at any time upon the question of the solubility of the precipitate, since its whole theory assumes the insolubility of the compound formed with lime or baryta, and this is found to vary with the different tannic acids, and in fact it is known that gambier and some other tanning materials do not give a precipitate at all with lime or baryta.

This objection to the method might be overruled if we could accept the assumption of Parker and Payne that "the majority of tanning materials depend upon the anhydrous digallic acid content for their activity as tanning agents." If this were true, and we were estimating the same thing every time, we might hope for a general method on these lines. Unfortunately, it is well recognised by all organic chemists that the tannins form a class of very varied constitution, and all the variations which Parker and Payne ascribe to the mysterious entity "colour-weight" are equally well explained by the much more natural view that the tannins vary in molecular weight, and, consequently, in their percentage-absorption by gelatinous fibres.

Again, the observed hydrolysis of digallic acid in the presence of alkalis is further evidence for the unreliability of the method. What occurs with digallic acid is only typical of what will happen, in all probability, with most other tannins, so that we have to face the question not only of the solubility of precipitates of the tannins with baryta and lime, but also that of the products of hydrolysis. These are not at all well investigated, and it is quite a possibility, for example, that some tannin would give protocatechuic acid as one of its products of hydrolysis which, as shown above, cannot be estimated by this method. As a general method of analysis, therefore, the process is useless, though it is quite possible that it might be so modified as to give reliable results in many cases for a given material. It is greatly to be regretted that we are driven to these conclusions, since the method appears at first sight very promising, especially on account of the sharp end-reaction of the reagents with phenolphthalein. A rapid process for the control of tannery liquors is very urgently needed, and if at the same time it could estimate their acidity, its value would be still further increased.

Discussion.

Mr. A. Guthrie said that he had tried the method when it was first published, but obtained disappointing results. Owing to the hot weather at that time, the temperature of the liquors was about 35° C., and this affected the solutions noticeably. Immediately after filtration the filtrate was clear, but quickly became turbid owing to rapid oxidation. High results were invariably obtained.

Mr. T. Fairley asked whether methylated spirits or pure alcohol was used in these experiments. It was commonly understood that these complex bodies were unstable in alkaline liquids, and pyrogallic acid was well known as a rapid absorbent of oxygen under such conditions. This property was possessed in a less degree by other similar bodies. He thought precipitation by salts of the heavier metals in place of those of the alkaline earths might be of use in the work.

Mr. F. K. Kopecky said he always thought that it was useless to attempt this kind of work with tannins in alkaline solutions.

Mr. H. G. Bennett thought there might be a possibility of working with tannins in alkaline solutions if free access of air were prevented. Errors due to this might be eliminated by using the special apparatus mentioned in the paper, in place of experiments conducted like those of Payne and Parker with open funnels and beakers, and exposed filtration. The whole method stood or fell on the solubility or insolubility of the precipitates, and, as this would vary with each tannin, it would be, therefore, necessary to determine the requisite quantity of alcohol to be used for each different tannin.

Prof. H. R. Procter, in reply, said that some of the salts of the heavy metals did give good results. He had tried precipitation with copper and treatment with ammonium carbonate, as Dreaper suggested, and obtained good results under certain conditions. Pure alcohol was used in all the experiments.

Meeting held at Leeds, on Monday, February 26th, 1906.

MR. THORP WHITAKER IN THE CHAIR.

THE ESTIMATION OF AMMONIA IN USED LIME LIQUORS.

BY H. R. PROCTER AND DOUGLAS McCANDLISH

(Contribution from the Leather Industries Department of the University of Leeds).

When a hide is placed in a fresh lime liquor, practically no unhairing action takes place at first. If the liquor has previously had hides taken through it, or is allowed to stand in contact with hide for a sufficient time, a putrefactive action takes place, due to the action of bacteria upon the organic matter of the hides. The lime will now have acquired the property of softening the epidermal layer in which the hair-roots are situated, so that the hair can be easily removed. In addition to this, it will exert a solvent action upon the hide itself. The exact nature of the products of the combined action of the bacteria and lime upon the hide is not known, but one thing is certain, that ammonia is always formed together with ammo-compounds of uncertain constitution. It may be said, speaking generally, that the amount of ammonia in a liquor is proportional to its age; the older it is, the more ammonia is present in it. As the solvent action of a liquor increases with the age, and ammonia itself has a solvent action, it follows that the ammonia will afford a standard by which the activity of a liquor may be judged. It is, therefore, of importance to the tanner to know the amount present in the "limes" with some degree of accuracy. The estimation of ammonia in such a liquor appears at first sight to be a simple matter, the method which naturally suggests itself is that of distillation in an ordinary Kjeldahl's ammonia

the true neutralisation-value of 100 c.c. N/50 gallic acid. This corresponds to absorption by 1 grm. of dry gallic acid of 125 c.c. N/5 baryta. Parker and Payne give 1 grm. dry gallic acid = 177·75 c.c. N/5 alkali ("Collegium," 1904, p. 267). This figure would correspond to the neutralisation of 5·69 eq. of alkali, by 1 eq. of gallic acid—obviously an impossible result, and presumably a clerical error.

2. *Protocatechuic acid.*—Some experiments were now made with N/50 protocatechuic acid (3·08 grms. per litre) with a view to determining the solubility of its barium precipitate, and also in the hope of confirming the above view of the constitution of these precipitates. It was found, however, that in aqueous solutions, no precipitate was produced, and that although alcohol did produce precipitation it by no means completed it, and that larger quantities of alcohol resulted merely in the baryta being thrown out of solution.

In a similar way, N/5 sugar-lime gave no precipitate with protocatechuic acid, and the addition of alcohol, even in small quantities, resulted in the precipitation of lime. It is by no means certain, though not improbable that free protocatechuic acid exists in natural tanning materials, but in any case it is a derivative of all catechol tannins, and its behaviour may probably be taken as typical.

3. *Digallic acid.*—These experiments were made with a commercial sample of pure gallotannic acid. The moisture was estimated (12 per cent.) at 100° C., and a N/50 solution made up, assuming the rest to be digallic acid (7·318 grms. per litre). If no alcohol was used, the neutralisation values varied between 50 and 60, and increased with standing:—

Stood.	Neutralisation value.
0 hours	49·0
24 ,,	54·3
36 ,,	59·5

As the filtrate oxidised on exposure to air, it was concluded that precipitation was not complete, and hence alcohol was again used. It is, of course, possible that this imperfect precipitation was due to the gallic acid which is present as a constant impurity. The neutralisation values now varied between 60 and 70, and still increased with the time of standing.

The effect of precipitating hot, and of heating was noticed, and after trying various times and conditions it was found that the results converged to a consistent neutralisation value of 76·0 after 1½ hours heating on the water-bath. As also observed with gallic acid, hot precipitation and subsequent heating was an advantage as regards rapid filtration. Concordant results were not obtained under any other conditions.

It was noted that, if the filtration be carried out immediately after precipitation, the results approximate to 60, which would correspond to the saturation of all the six hydroxyl groups of digallic acid; but that if the mixture be allowed to stand or is heated, the value increases. This is best explained on the assumption that the digallic acid is hydrolysed by the action of the baryta, and that 2 mols. of gallic acid being produced, the true neutralisation-value approximates now to 80, the lower number actually found being due to the non-tannin impurities present in the sample; since any gallic acid present would be estimated along with that produced by hydrolysis and would not cause very serious error.

Experiments with N/5 sugar-lime.

1. *Gallic acid.*—Some preliminary experiments with varying excess fully bore out the remarks made in case of baryta as to the unreliability of using large excesses, both on account of co-precipitation and from the magnitude of the error which is involved in small differences in titration.

When no alcohol was used, the filtrate was easily oxidisable on exposure to air, though perhaps to a less extent than in the case of baryta, and hence the addition of alcohol was again tried. The error due to co-precipitation was, however, much more considerable in this case than with baryta, and was perceptible even when the alcohol was diminished to comparatively small quantities, the neutralisation values decreasing with the decrease of alcohol from 50 towards 40.

The actual results are as follows:—

Precipitation hot, and mixture heated half an hour, 150 c.c. of gallic acid solution and 100 c.c. of sugar-lime (N/5).

Added alcohol.	Neutralisation value.
50 c.c.	49·2
40 c.c.	47·9
30 c.c.	46·7
20 c.c.	45·5
10 c.c.	44·1
5 c.c.	13·6
(Precipitation cold and mixture not heated.)	
(Filtered at once.) 50 c.c.	47·0
(After standing two or three days with occasional shaking.) 50 c.c.	49·3
50 c.c. water and no alcohol	42·0

The results confirmed the view that the real neutralisation value is 40, corresponding to the saturation of all hydroxyl groups; but we have not yet succeeded in the case of sugar-lime of eliminating at the same time both the errors of co-precipitation and of solubility.

Some experiments were made using cane-sugar syrup in place of alcohol, in the hope of rendering the precipitate insoluble by virtue of its alcoholic structure, and at the same time abolishing co-precipitation, but the result showed that sugar to have a very peculiar effect on the lime precipitation, changing its colour, bringing a great deal of it into solution, making the filtrate deep yellow and much more easily oxidisable, and rendering the end-point of the titration indefinite. The results showed also a considerable increase in the neutralisation value, which rose to 49·2. What this means is difficult to see, but the sugar evidently introduces another unknown chemical change, and still further complication in the method, and is therefore best avoided altogether. Experiments with sugar-baryta fully bore out the above observations, quite similar effects being observed.

2. *Protocatechuic acid* was not experimented with quantitatively with sugar-lime for similar reasons to those which prevented its titration with baryta (v.s.).

3. *Digallic acid.*—It was thought desirable to confirm the view as to the hydrolysis of digallic acid by alkalis by making a few experiments with sugar-lime in addition to those with baryta. No alcohol was used. The results show neutralisation values of about 50 when the mixture is filtered and titrated at once, and that this increases with time and with heating until the figure reaches 74·8, which is obtained after two hours' heating on the water-bath. This fully bears out the theory that the digallic acid is, as one would expect, hydrolysed by the lime to 2 mols. of gallic acid, and the near agreement between the figures obtained when the reaction is complete for both baryta and lime, is an interesting confirmation of the idea that the discrepancy from the theoretical 80 is due to the impurity of the sample.

Further experiments.

Some experiments have also been made with the tannin of quebracho. An aqueous solution of the partially-purified tannin was made, and by repeated filtration through the candle was made clear.

1. 50 c.c. contained 0·2124 grm. soluble matter. 150 c.c. when mixed with 100 c.c. N/5 sugar-lime gave a reddish-brown precipitate, which was filtered at once with the usual apparatus. The filtrate was deep yellow, and easily oxidisable, with precipitation. The result showed that 100 c.c. of the solution absorbed 21·85 c.c. of N/5 alkali (*i.e.*, 1 grm. dry substance = 51·43 c.c. sugar-lime).

2. The same quantities of tannin and baryta solution were now mixed, and, as it was noticed that the filtrate was as yellow as before, the solution was made up to 300 c.c. with alcohol, and filtered. The filtrate was now decidedly less yellow, but the colour and oxidisability were still present. The result showed 100 c.c. tannin solution = 23·21 c.c. N/5 baryta, *i.e.*, 1 grm. dry substance = 54·21 c.c. N/5 baryta.

3. A further experiment, in which the sugar-lime (100 c.c.) was added to the hot tannin solution (150 c.c.) and

top of the tube. Over the top of B is placed the inverted head of a thistle funnel, the aperture where the stem was connected having been carefully sealed. This acts as a distributor for the liquid which is carried up tube B, causing it to run back evenly over the broken glass contained in the tube. The tube A is connected with U-tubes, containing sulphuric acid and caustic soda, to remove any ammonia and carbon dioxide contained in the laboratory air (as shown in Fig. 2), the other outlet of the boiling-tube being connected to a U-tube containing normal acid, which in turn is connected to the vacuum pump. It is advisable to have a spray catcher (a bulb containing glass beads) attached to the normal acid tube, in order that there may be no loss when air is rapidly drawn through the acid.

The estimation of ammonia is carried out in the same way as in the previous method. The filled tube is placed in the water-bath raised to 90° C., and the ammoniacal liquor introduced through A, a filter-funnel being attached for this purpose, and slight suction applied at the outlet tube to facilitate the operation. It is found convenient to use 50 c.c. of lime-liquor and absorb the ammonia in 30 to 40 c.c. of N/50 sulphuric acid, but the strength of the latter should be increased if very old lime liquors are being examined. When the experiment is in progress, the liquor is continuously raised to the top of tube B, thrown back by the thistle-funnel upon the broken glass and runs to the bottom of the tube. In this way a continuous circulation of the liquor takes place. It was proved that all the ammonia was driven off from known quantities of ammonium salts in 30 minutes, and that on repeating the determination several times with the same lime-liquor consistent results were obtained. There is no difficulty caused by frothing, as the thistle-funnel breaks any bubbles which are formed, and so does away with this source of trouble. Beyond the preliminary work of fixing up the apparatus there is not much trouble in carrying out the determination by this method. A point which specially commends it to a chemist in a tannery is that after having been started, the experiment requires no further attention until the half hour is completed and the final titration of the acid has to be made. Obviously, if preferred, air can be forced instead of sucked through the apparatus.

DISCUSSION.

Mr. THORP WHITAKER said he was much impressed by the similarity of the useful apparatus described, to the Soxhlet extractor. They were alike in working continuously.

Mr. T. FAIRLEY thought the method might turn out to be of use in the estimation of ammonia in many cases where heat was undesirable. In the estimation of ammonia in urine he had known it necessary to let the urine stand six or seven days over sulphuric acid. If fermentation set in, the decomposition of urea might result, with consequent error. Any method, therefore, which gave hopes of differentiating between ammonia originally present in bodies and that formed from derivatives of ammonia during the process of treatment with alkali and distillation, would be welcome.

Mr. D. MCCANDLISH mentioned that the air was freed from carbon dioxide before passing through the apparatus, in order to prevent deposition of calcium carbonate on the broken glass. If this took place it would necessitate constant cleaning of the apparatus.

Prof. H. R. PROCTER said that a larger amount of broken glass might be useful. The idea of raising a liquid by a current of air could be applied to several methods. He thought the old method for the determination of small quantities of ammonia was now quite discredited.

ENGLISH PATENTS.

Tanks [Settling] for the purpose of producing a liquid free from suspended solids. J. Fieldhouse, London. Eng. Pat. 2520, Feb. 8, 1905.

THE tank consists of two parts—an inner one, cylindrical in shape and conical at the bottom, which is surrounded by an outer circular tank divided into two or more radial compartments and also conical at the bottom. The inner tank serves as a distributing chamber, and communicates by separate conduits with the outer tanks, which serve as settling chambers. Sludge valves are provided at the bottom of the tanks, the one at the bottom of the inner tank being protected by a cone-shaped arrangement which prevents deposition of sludge on the sloping walls of the lower part of the tank. From the outer tank the clear liquid flows under scum boards over a sill into a collecting channel, which leads to the discharge pipe. The scum boards are movable, and when lowered allow the scum to be periodically run off through a separate valved channel.—W. P. S.

Disintegrating, drying and mixing machine. H. L. M. Mundy, J. R. Broadley, and H. S. Rhodes, Leeds. Eng. Pat. 4426, March 3, 1905.

THE materials to be treated are placed in a horizontal cylindrical vessel supported by a hollow shaft on trunnions, and surrounded by an outer, double-walled, horizontal cylinder, forming a heating jacket. Either, or both of the cylinders may be rotated, and in the same or in opposite directions. The inner cylinder is provided with arms or beaters which may be attached either to the interior of the cylinder, or to the shaft, and also with a conveyor, or with rakes, for the purpose of removing the material when treated. The materials are charged and the vapours evolved escape, either through the hollow shaft and trunnions, or through special openings in the ends of the cylinder.—W. H. C.

High temperatures; Apparatus for measuring ——. A. F. Spooner, London. From La Compagnie pour la Fabr. des Compteurs et Materiel d'Usines à Gaz, and C. Fery, Paris. Eng. Pat. 5668, March 17, 1905.

THE invention relates to the high temperature measuring apparatus described in Eng. Pat. 18,382 of 1904 (this J., 1905, 210), which consists of a thermo-electric telescope and a recording galvanometer. A number of movable sector-shaped screens are placed in front of the mirror which concentrates the heat rays upon the thermo-couple. The screens can be moved by a screw so that any desired sector-shaped fraction of the surface of the mirror can be exposed to the heat rays. The position of the screens is indicated by a pointer on a graduated circle, and the instrument is calibrated for different ranges of temperature. For comparatively low temperature observations a large portion of the surface of the mirror is used, and for higher ranges of temperature correspondingly smaller fractions of the surface of the mirror are left uncovered by the screens. In this way the whole range of temperatures which can be measured by the same instrument is increased.—W. H. C.

UNITED STATES PATENTS.

Separating-machine. H. Baldwin, Youngstown, Ohio. U.S. Pat. 812,972, Feb. 20, 1906.

THE materials to be separated are delivered into a feeding-

placed just inside a tapering chamber near its larger , which has openings at the same end for the discharge the coarser and heavier particles, and at the smaller for the lighter and finer ones. A blast of air is intro- ed with a whirling motion into the larger end by an rnal fan; the air carrying forward the lighter particles ses through the apparatus, leaves at the smaller end is returned to the fan. The internal feeding fan is losed by a "peripheral wall" provided with an adjust- s opening, through which the materials to be treated directed into the whirling air current.—W. H. C.

er-press. S. Thurstensen, Assignor to H. Vogt lachine Co., Louisville, Ky. U.S. Pat. 813,121, eb. 20, 1906.

s claim is for a filter-press into which the material to iltered is fed by a rotating worm or screw, which passes ig the whole length of the press through openings ged near the upper end of each plate. The plates ribbed and covered by filter-screens attached to the es, and any undue pressure on the latter is avoided projections or "hubs," which extend through the le length of the press.—W. H. C.

FRENCH PATENTS.

er for pulp. L. C. Trent. Fr. Pat. 358,538, Oct. 14, 1905.

GERMAN PATENTS.

uids under pressure; Device for the filtration of ——. Grosz and Ganz und Co., Akt.-Ges. Ger. Pat. 3,135, Nov. 7, 1902.

filtering device consists of a flat slab of porous ter-stone" covered by a sheet of filter-paper, which eld in place upon the filter-stone by the inflowing d.—A. S.

ring [Photographic developers, &c.]; Apparatus —— *with exclusion of air.* P. Dinglinger. Ger. t. 162,821, Aug. 28, 1904.

apparatus consists of two bottles fitted air-tight on r side of a stopper. The stopper has two holes gh which tubes pass, the upper end of one tube flush with the upper side, and the lower end of the tube flush with the lower side of the stopper. One e tubes contains paper-pulp, glass-wool or the like, acts as a filter. One of the bottles is filled with the d to be filtered, the different parts of the apparatus itted together, and the whole is reversed, when the d flows through the filter into the other bottle. The ratus is recommended for the filtration of photographic lopers.—A. S.

ensation mist; Process for the prevention of ——. J. Ephraim. Ger. Pat. 163,370, Nov. 10, 1903.

he condensation of vapour, the formation of fine frequently offers difficulties, as the extremely fine cles of liquid of which the mist is composed, pass gh the condenser unchanged. According to the nt invention, the gaseous mixture containing the mist is warmed until the latter has partially dis- ared, and is then again cooled. In this way the particles of liquid are converted into vapour, which, bsequent cooling, condenses to larger drops that are ed by the condenser. The operations may be ted as often as is necessary.—A. S.

orating apparatus. S. Duffner. Ger. Pat. 163,444, March 9, 1904.

Invention relates to evaporating apparatus, in which ylindrical heating units are arranged in tiers, with rtical heating tubes of one unit disposed directly the corresponding tubes in the unit below. Accord- ing to the present patent the heating units increase or decrease, or otherwise vary in diameter from the lowest one upwards, and are so arranged that sufficient space is left between them and the walls of the evaporator for the free downward movement of the liquid being evaporated, whereby, it is claimed, effective circulation is ensured.—A. S.

Coal-testing in America. Times, Eng. Supp., March 7, 1906.

THE United States Government has, with the sanction of Congress, decided to continue the work of testing the coals and lignites of the various States. This work was begun at St. Louis, during the exhibition, under the supervision of the Director of the United States Geological Survey. Congress has made the necessary appropriation for the present year, and it is probable that coal-testing will become one of the permanent duties of the Geological Survey. The mines are sampled under the rules prescribed by the Geological Survey and the American Chemical Society. When the coal is received at the plant, and as it is unloaded, it is sampled by taking small quantities at frequent intervals from the conveying apparatus, the coal in the meantime having been passed through rolls and reduced to a uniform size—1½ ins., and smaller. From the conveyors the coal is transferred to storage bins, and as drawn from these for testing purposes, at different portions of the plant, it is again sampled for analysis. Some of the conclusions of the preliminary report are as follows: (1) When coal is converted into gas and used in a gas engine, its average efficiency for power purposes is from 100 to 150 per cent. greater than when used under boilers. (2) The poorer grades of coal, rated according to their steam-raising qualities, give better results in the gas producer than the higher grades of steam coals. (3) Lignites used in the gas producer, in power-raising efficiency are equal to or better than steam coals used under boilers. (4) Many coals high in sulphur or ash can be materially improved for steaming, coking, or briquetting purposes by washing. (5) Some non-coking coals can be made to produce a fair quality of coke by an addition of coal-tar pitch to the charge of coal. A comparative statement of some of the results obtained at the coal-testing plant in the generation of power (1) by the boiler and steam engine, and (2) by the producer and gas engine, shows a saving in favour of the latter method (eliminating any possible differences of cost of installation and of operation) of more than 50 per cent. in every instance, and in one case the amount of coal consumed per horse-power per hour by the boiler plant was nearly three times that used in the producer. [T.R.]

ENGLISH PATENTS.

Filaments for electric incandescent lamps; Manufacture of incandescing ——. A. Just and F. Hanaman, Budapest, and Ver. Elektricitäts Act.-Ges., Ujpest, Hungary. Eng. Pat. 11,949, June 7, 1904.

SEE Addition of June 10, 1905, to Fr. Pat. 347,661 of 1904; this J., 1905, 1220.—T. F. B.

Nickel; Production of ——. H. S. Elworthy, St. Albans, and E. H. Williamson, London. Eng. Pat. 7714, April 11, 1905.

NICKEL oxide or other nickel compound is first reduced by heating at 400° C. in hydrogen, water-gas or other reducing gas, and the metallic nickel produced is then further heated at 1200° C. in an atmosphere of hydrogen or other inert gas for some time. The porous and coherent mass is then crushed to grains of the required size, which may be used as the active material for converting oxides of carbon and hydrogen into methane, according to Eng. Pats. 12,461, of 1902, and 14,333 of 1904 (this J., 1903, 900; 1905, 1006).—A. G. L.

United States Patents.

Gas producing and consuming apparatus; Power ——, C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 812,194, Feb. 13, 1906.

This system for the production and consumption of power-gas comprises a gas-producer, from which the gas is led by a pipe, which passes through a cooling vessel containing water, to a gas engine. The products of combustion are taken from the engine by a pipe, which also passes through the cooling vessel, and are returned to the producer. Means are also provided for mixing with the products of combustion, after they have passed through the cooling vessel, air from the atmosphere, and steam from the water vaporised in the cooling of the products of combustion.—W. C. H.

Gas; Apparatus for producing — —. C. Marconnet, Paris. U.S. Pat. 813,726, Feb. 27, 1906.

See Fr. Pat. 340,075 of 1904; this J., 1905, 745.—T.F.B.

Gas washer and scrubber; Combined — —. L. P. Lowe, San Francisco, Cal. U.S. Pat. 812,217, Feb. 13, 1906.

The combined gas washer and scrubber consists of an L-shaped shell. The horizontal portion is provided with an overflow, and with a gas-inlet which extends below the level of the overflow. It is divided into two chambers by a transverse partition, and the vertical portion—or scrubber—is also divided into two chambers by a vertical partition. The shell of the vertical portion, next to the horizontal portion, extends into the latter, but not to the bottom. The gas enters the horizontal portion—or washer—passes over the transverse partition in it, and up the first chamber of the vertical portion to the top, from which it is conducted by a pipe to the bottom of the second chamber; and in each of these chambers a spray is provided.—W. C. H.

Gas purifier. L. P. Lowe, San Francisco, Cal. U.S. Pat. 812,218, Feb. 13, 1906.

The purifier consists of a casing divided vertically into a horizontal series of chambers; each chamber is provided with a vertical partition dividing it into two compartments, which are connected at the bottom. At the bottom of each chamber is a door, opposite to the vertical partition. Movable supports are arranged in each compartment for purifying material. Over the chambers, and parallel to them is a pipe, which communicates with the chambers by valved connections; valves are also arranged in the pipe over each partition. By this system the gas is passed in succession through the chambers.—W. C. H.

French Patents.

Combustible gaseous mixture; Process and apparatus for producing a ——. C. K. Harding. Fr. Pat. 358,620, Oct. 18, 1905.

See U.S. Pat. 803,534 of 1905; this J., 1906, 170.—T.F.B.

Filament; [Electric furnace for making] An indestructible —— *for lighting and heating.* G. Michaud and E. Delasson. Second Addition, dated Sept. 30, 1905, to Fr. Pat. 346,307, Sept. 17, 1904. XII., page 271.

German Patents.

Lignite and the like; Process for briquetting — *by means of magnesium oxychloride (magnesia cement) produced within the same.* A. Eckl. Ger. Pat. 163,365, Oct. 22, 1903.

The dry lignite is impregnated with hydrochloric acid gas, and then mixed with a paste of magnesia and water. —A. S.

Retort; Vertical—— for the manufacture of coal gas. J. Hasse. Ger. Pat. 163,533, July 24, 1903.

The gas-outlet pipe extends centrally through the retort and is provided with openings through which the gas passes from the retort into the pipe. The retort is narrower at the top than at the bottom, whilst the gas-outlet pipe tapers in the reverse manner. In the closing device at the bottom of the retort, are one or more channels through which water-gas, oil-gas, carburetting agents, or the like may be introduced and mixed with the coal-gas produced in the retort. The chief advantage of this form of retort is that the shape and size of the annular retort chamber can be altered at will by replacing the gas-outlet pipe by another of different form.—A. S.

Retort; Vertical —— for carbonising peat. F. Sellnow. Ger. Pat. 165,266, Sept. 30, 1903.

The retort is heated by means of an outer heating jacket, a central vertical tube, and two transverse tubes at the top and bottom respectively, all communicating with one another and with the chimney. On the under side of the lower transverse heating tube are openings through which a strong draught is created by the chimney. The gaseous and tarry decomposition products formed above this heating tube are thus sucked down through the layer of hot peat-charcoal below the heating tube, before escaping to the chimney.—A. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 216.)

Hydroxybenzoic acids; Some oxidation products of the ——. *II.* A. G. Perkin. Chem. Soc. Trans., 1906, **89**, 251—261.

The present paper deals with the oxidation products obtained from gallic acid by the action of potassium persulphate in presence of dilute and of strong sulphuric acid (see this J., 1905, 1087). In dilute sulphuric acid solution, the chief oxidation product consists of a pale brown substance, which, after being purified by crystallisation from pyridine, forms small, pale yellow, prismatic needles, which do not melt below 360° C. The compound, flavellagic acid, $C_{14}H_8O_9$, yields a penta-acetyl derivative melting at 317°—319° C. On treatment with boiling potassium hydroxide solution, it yields a compound, $C_{13}H_8O_8$, closely resembling the pentahydroxydiphenylmethylolid obtained in a similar manner from ellagic acid and which is, therefore, considered to be the corresponding hexahydroxy compound. The following formula is given for flavellagic acid:—

Flavellagic acid closely resembles ellagic acid, but has a somewhat yellower appearance, whilst its solution in alkali

has a well-marked green tint. When treated with nitric acid containing nitrous acid it gives, on subsequent dilution, a blood-red coloration (Griessmayer reaction), which has long been considered as characteristic of ellagic acid. It dyes mordanted wool in shades similar to, but stronger than those produced by ellagic acid, *viz.*, on chromium mordant, yellowish-olive; on aluminium, pale greenish-yellow; on tin, pale yellow; and on iron, dark olive-brown.

By the oxidation of gallic acid, dissolved in concentrated sulphuric acid, a mixture of ellagic and flavellagic acids is produced.—A. S.

Diazo-compounds from diamines (o-, m-, and p-Diamines; benzidine). L. Vignon. Bull. Soc. Chim., 1906, **35**, 126—129.

THE author endeavoured to combine the tetrazo-compounds of *m*- and *p*-phenylenediamine with aniline to form diazoamino compounds of the type $C_6H_4(N_2.NHC_6H_5)_2$ but without success. The action of 2 mols. of diazobenzene solution on 1 mol. of *o*-, *m*- and *p*-phenylenediamine respectively in presence of excess of potassium carbonate and a large quantity of alcohol was then investigated, in the hope that the diazo groups might be transferred from the one nucleus to the other. With *o*-phenylenediamine a tarry unstable mass was obtained, which evolved much nitrogen with acids. It could not be purified or analysed, but the author considers that it is probably $C_6H_4(NH.N_2.C_6H_5)_2$. With *m*-phenylenediamine a smoother reaction was observed. In presence of sodium acetate a red precipitate was obtained, which gradually became tarry and formed a reddish-brown magma. On washing with water and crystallising from alcohol, reddish-yellow crystals of Chrysoidine were obtained. The author considers that these were formed according to the following equations:—

$$2C_6N_2.N_2Cl + C_6H_4(NH_2)_2 = C_6H_4(NH.N_2.C_6H_5)_2 + 2HCl \text{ and}$$
$$C_6H_4(NH.N_2.C_6H_5)_2 + H_2O = C_6H_5N_2.C_6H_3(NH_2)_2 + C_6H_5OH + N_2.$$

In presence of *p*-phenylenediamine, diazobenzene solutions decomposed violently. The author has obtained a series of new derivatives, which he will describe later, by combination of tetrazotised benzidine with aniline.—E. F.

Diaminoanthraquinones. E. Noelting and W. Wortmann. Ber., 1906, **39**, 637—640.

MENTION is made in Beilstein's "Handbuch der organ. Chem." of the following diamino compounds, some of which form the subject of the present investigation:—(1) *a*-Diaminoanthraquinone (Anthracene Orange) melting at 236° C., obtained by Boettger and Petersen from dinitroanthraquinone; (2) *β*-diaminoanthraquinone prepared from dinitroanthraquinone according to Fritzsche; (3) 1.2-diaminoanthraquinone obtained from alizarin and ammonia, which has been proved to be an imide and not a diamino compound, the true 1.2-derivative being formed by nitrating the ester of 1-aminoanthraquinonecarbamic acid and subjecting the product to hydrolysis and reduction; (4) 1.5-diaminoanthraquinone obtained by Roemer; and (5) 1.4-diaminoanthraquinone. A 2.6-derivative melting at 310°—312° C. has also been obtained by heating the corresponding disulphonic acid with ammonia.

The dinitroanthraquinone obtained by Roemer by the action of nitric acid on a solution of anthraquinone in strong sulphuric acid is said to be a mixture of the 1.5-derivative, the *a*-derivative described by Boettger and Petersen and a *δ*-derivative. By reducing this compound with sodium sulphide and treating the product with sulphuric acid, the authors obtained a soluble and an insoluble portion, from which they isolated respectively the 1.8- and 1.5-diamino compounds. The former melts at 262° C., is sparingly soluble in ether, but dissolves readily in other solvents; whilst the latter melts at 319° C., and yields anthrarufin when diazotised. They, however, failed to obtain evidence of the existence of the *a*-compound described by Boettger and Petersen. From the dinitroanthraquinone prepared by Fritzsche by heating anthracene with dilute nitric acid, the authors by the action of reducing agents obtained 2.7-diaminoanthraquinone, which crystallises from alcohol in orange-yellow needles melting above 330° C., and yields iso-anthraflavic acid on diazotisation. For the production of the 1.4-derivative, *a*-aminoanthraquinone was acetylated, nitrated, hydrolysed and reduced, or its oxamic acid was nitrated in sulphuric acid solution and reduced with sodium sulphide in an alkaline solution. The tetra compound was obtained by nitrating the dioxamic acid of 1.5-diaminoanthraquinone suspended in strong sulphuric acid and reducing the dinitro compound. It crystallises in reddish-brown needles melting at 332° C. Attempts to produce triaminoanthraquinone from the diamino derivative by nitration led to the formation of dinitrodiamino compounds.—D. B.

Morin; Synthesis of ——. St. v. Kostanecki, V. Lampe and J. Tambor. Ber., 1906, **39**, 625—628.

MORIN (1.3.2′.4′.tetrahydroxyflavonol) was prepared synthetically in small quantity by heating 2′-hydroxy-4′.6′.2.4-tetramethylchalkone,

$$(CH_3O)_2(OH)C_6H_2.CH{:}CH.C_6H_3(OCH_3)_2,$$

with dilute acids in alcoholic solution; converting the 1.3.2′.4′-tetramethylflavanone,

$$(CH_3O)_2.C_6H_2\langle \begin{matrix} O \\ CO.CH_2 \end{matrix} \rangle CH.C_6H_3(OCH_3)_2,$$

into *a*-isonitroso-1.3.2′.4′-tetramethoxyflavanone,

$$(CH_3O)_2.C_6H_2\langle \begin{matrix} O \\ CO.C{:}N(OH) \end{matrix} \rangle CH.C_6H_3(OCH_3)_2$$

by means of amyl nitrite and hydrochloric acid; and then boiling the latter substance with hydriodic acid (sp. gr., 1.9). It is obtained from dilute alcohol as a light yellow crystalline powder, m. pt., 290° C., which dissolves in concentrated sulphuric acid with a light yellow, strongly fluorescent colour. A direct comparison with the natural product showed the identity of the two substances.—H. L.

Triphenylmethane dyestuffs united by a glutaconic aldehyde chain; Influence of methyl groups on the shade of ——. F. Reitzenstein and J. Rothschild. J. prakt. Chem., 1906, **73**, 192—206.

By treating triphenylmethane dyestuff leucobases with dinitrophenylpyridine chloride according to Zincke's method (Annalen **333**, 314), dinitraniline is formed together with substances such as that represented by the formula:—

$$[(CH_3)(NH_2)C_6H_3]_2{:}CH.C_6H_4.N{:}CH.CH{:}CH.CH{:}CH.NH_2Cl.C_6H_4.CH{:}[C_6H_3(NH_2)(CH_3)]_2$$

in which two triphenylmethane dyestuff nuclei are coupled together by the glutaconic aldehyde chain. The condensation products are stated to produce brighter and stronger shades than an equal quantity of the original dyestuffs. The dyeing power is weakened by the introduction of methyl groups in the *o*-position. (See Reitzenstein and Runge, J. prakt. Chem., **71**, 57.)—H. L.

Persian berry colour. U.S. Customs Decision, Jan. 26, 1906.

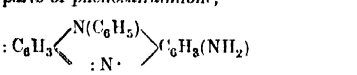
THE claim of the importer that sulphonated Persian berry colour is dutiable at ½*c.* per lb. under paragraph 22 of the tariff was overruled. The article in question is used for colouring food products, and the Board expressed the view that it was dutiable at 20 per cent. *ad valorem* under section 6 as a "manufactured article, unenumerated."

[T.R.] R. W. M.

ENGLISH PATENTS.

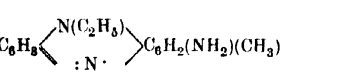
Dye; Process for the manufacture of a yellow sulphur —— [*Sulphide dyestuff*]. Chem. Fabr. vorm. Weiler-ter-Meer, Uerdingen-on-Rhine, Germany. Eng. Pat. 5449, March 15, 1905. Under Int. Conv., March 23, 1904.

SEE Ger. Pat. 157,862 of 1904; this J., 1905, 615.—T. F. B.



Indigo preparations; Manufacture of ——. O. Imray, London. From Farbw. vorm. Meister, Lucius und Brüning, Hoechst-on-Maine, Germany. Eng. Pat. 7390, April 7, 1905.

FINELY-DIVIDED indigo is mixed, preferably whilst moist,



with a saccharide soluble in water and useful or non-injurious in a fermentation vat, the saccharide being of such concentration that it prevents or hinders the growth of micro-organisms such as moulds, &c., which might damage the dyestuff when the product is stored. A product is thus obtained which is more readily miscible than pure indigo with the liquid of the dye-vat. The manufacture may be carried out in many ways, for instance, by mixing indigo paste with syrup, glucose, molasses, &c., and evaporating *in vacuo* or in cans or drums to a highly concentrated paste or solid. For example, 800 parts by weight of indigo are used with 500 to 2000 parts by weight of molasses to produce pastes of 40 to 60 per cent. strength; or indigo cakes are pressed, by preference hydraulically, and the product stirred in a kneading machine with molasses, melted glucose, &c. This process may also be applied to tolyl-indigos, halogenated indigos and their homologues.—E. F.

Dyestuffs [*Sulphide dyestuffs*]; *Manufacture of red, dark red to violet sulphurised* ——. O. Imray, London. From Farbw. vorm. Meister, Lucius und Brüning, Hoechst-on-Maine, Germany. Eng. Pat. 14,543, July 14, 1905.

HYDROXYLATED azines, or their alkyl, aryl, sulphonic, carboxylic and like derivatives, or their sulphurised derivatives, are heated with alkali polysulphide in presence of copper or of copper compounds. The effect of the copper is such that the shade of the dyestuff which is produced is much redder, whilst at least equally clear, and, therefore, more valuable, than if no copper is present; also, the resulting dyestuffs are much faster to light. The reaction is carried out either by the so-called melt-process, in which case it is advantageous to use a reflux condenser to maintain a constant temperature and concentration, or by boiling an aqueous or alcoholic solution of the material and the sulphide, or a solution of the sulphide with the material in suspension. By preference an enamelled or lead-lined vessel is used, as iron influences the shade. Copper vessels are not very practical as an indefinite amount of copper enters into reaction. For example, 15 parts of the hydrochloride of 2-amino-2'-hydroxyphenazine are heated with 83 parts of crystallised sodium sulphide, 38 parts of sulphur and 10·5 parts of crystallised copper sulphate dissolved in 20 parts of hot water. The mixture is first evaporated till the temperature attains 110° C.; a reflux condenser is then attached and heating continued for about five hours. The product dyes in bluish copper-red shades from a sulphide bath. Again, for example, 15 parts of phenosafraninone,

are heated gradually to about 135° C., whilst stirring, with 85 parts of crystallised sodium sulphide, 37·5 parts of sulphur and a quantity of copper sulphide paste corresponding to 10·5 parts of crystallised copper sulphate. This dyestuff yields strong reddish-violet shades, very fast to light. If the phenosafraninone be replaced by the ethosafraninone

from *p*-nitrosophenol and *m*-monoethyltoluylenediamine, a Bordeaux red dyestuff is obtained, said to be of previously unattained clearness and beauty, and very fast to light.—E. F.

Polyazo colours [*Azo dyestuffs*]; *Manufacture of* ——. R. B. Ransford, Upper Norwood. From L. Cassella und Co., Frankfort on Maine, Germany. Eng. Pat. 13,804, July 4, 1905.

SEE U.S. Pat. 807,119 of 1905: this J., 1906, 65.—T. F. B.

Zinc-formaldehyde hydrosulphite; *Manufacture of* ——. J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 81, Jan. 1, 1906.

ACCORDING to Eng. Pat. 7592 of 1905 (this J., 1905, 1299 and 1300), a zinc-formaldehyde sulphoxylate, soluble with difficulty in water, can be obtained by the interaction of zinc dust, sulphur dioxide and an aqueous formaldehyde solution at about 100° C., or by stirring for a considerable time in the cold. According to the present patent a readily soluble zinc-formaldehyde hydrosulphite is obtained by the interaction of the above-mentioned components, with cooling, or with avoidance of external heating, if the reaction is stopped before the difficultly soluble zinc-formaldehyde sulphoxylate separates. For example, 357·5 parts of zinc dust are suspended in 2000 parts of a 15 per cent. aqueous formaldehyde solution and a current of sulphur dioxide is passed in, with stirring, until the increase in weight is about 640 parts. The temperature is preferably maintained at about 20° C. by cooling, and should not in any case exceed 50° C. The liquid is then filtered from the residue of zinc dust and evaporated to a syrup.—E. F.

UNITED STATES PATENTS.

Dye and process of making same; Red azo ——. G. Kalischer, Frankfort on Maine, Germany, Assignor to Cassella Colour Co., New York. U.S. Pat. 813,155, Feb. 20, 1906.

ONE mol. of an aromatic diazonium compound is combined, in alkaline solution, with 1 mol. of 5-hydroxynaphthodiaminobenzaldehydin-7-sulphonic acid (see U.S. Pat. 807,117 of 1905; this J., 1906, 65). The dyestuff is soluble in water giving a red solution, and in sulphuric acid to a bluish-red solution.—T. F. B.

Dye [*Sulphide dyestuff*] *and process of making same; Orange-yellow sulphur* ——. R. Gley, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 813,643, Feb. 27, 1906.

FRENCH PATENTS.

Dyestuffs of the anthracene series; Production of ——. Soc. Anon. des Produits F. Bayer et Cie. Second Addition, dated Sept. 7, 1905, to Fr. Pat. 343,608 of March 29, 1904. Under Int. Conv., Nov. 21, 1904.

YELLOW dyestuffs are obtained by treating 1.3-dihalogeno-2-aminoanthraquinones with metallic salts in presence of strongly alkaline substances such as alkali hydroxides, sodium amide, &c. The new dyestuffs dissolve in alkalis in presence of reducing agents, forming a blue vat which dyes unmordanted cotton in blue shades turning to yellow by the action of the air. For example, a mixture of 100 kilos. of 1.3-dibromo-2-aminoanthraquinone, 1000 kilos. of nitrobenzene, 5 kilos. of cupric chloride and 40 kilos. of sodium hydroxide is heated to 150° C. for two to four hours until the quantity of yellow dyestuff no longer increases. The melt is allowed to cool to 100° C., and the precipitate filtered off and washed with nitrobenzene, alcohol, and dilute hydrochloric acid. It may contain small quantities of the blue dyestuff described in the original patent, which can be separated, as it crystallises out from a mixture of equal parts of sulphuric acid of 66° B. and 60° B. respectively, in which the yellow dyestuff remains dissolved. Its solution in sodium hydroxide solution dyes cotton in blue shades turning to brownish-yellow in the air. The nitrobenzene in the above method of preparation may be replaced by other diluents such as naphthalene.—E. F.

Dyestuffs of the anthracene series; Production of new ——. Soc. Farbenfabriken vorm. F. Bayer und Co. Fr. Pat. 358,271, Oct. 4, 1905. Under Int. Conv., Feb. 11, 1905.

IT is already known that by treating dinitroanthrarufindisulphonic acid with alkali sulphides in alkaline solution, the nitro-groups are reduced in a normal manner, diaminoanthrarufindisulphonic acid being formed. This substance is a blue dyestuff, known commercially as "Alizarinsaphirol B." According to the present patent, if dinitroanthrarufindisulphonic acid is treated with alkali sulphide in neutral or weakly acid solution, an entirely different

dyestuff is obtained which yields very pure green shades on unmordanted wool. This same product may also be produced by other methods, as follows:—When dinitroanthrarufindisulphonic acid is treated with hydrogen sulphide in neutral or weakly acid solution, a new product is obtained, dyeing wool in violet shades, which the patentees call "the intermediate product." When this intermediate product is heated with alkali sulphides or hydrosulphides it forms the above-mentioned green dyestuff very readily. The latter is also obtained by prolonging the action of hydrogen sulphide on dinitroanthrarufindisulphonic acid in neutral or weakly acid solution, or by treating the intermediate product with hydrogen sulphide. The green dyestuff forms an addition product with hydrogen sulphide. This is also produced by prolonging still further the action of hydrogen sulphide on dinitroanthrarufindisulphonic acid in neutral or weakly acid solution, or on the intermediate product. It is readily converted into the green dyestuff; for instance, by heating with water. The new green dyestuff may also be obtained by the action of thiosulphuric acid or its salts on dinitroanthrarufindisulphonic acid in neutral or acid solution. This reaction is accelerated by the addition of an alkali sulphite. The new dyestuff is probably formed by simultaneous reduction and introduction of sulphur into the molecule. It forms a green sodium salt, only very slightly soluble in dilute sodium hydroxide solution, by means of which it may be purified and separated from diaminoanthrarufindisulphonic acid. It dyes unmordanted wool in green shades from an acid bath, and chrome-mordanted wool in yellowish-green shades. For example 10 kilos. of the sodium salt of dinitroanthrarufindisulphonic acid are dissolved in 700 litres of hot water and 10 kilos. of 50 per cent. acetic acid. A solution of 25 kilos. of crystallised sodium sulphide in 100 litres of water is then added at 75° C., with stirring. At first, whilst the liquid is still acid, the intermediate product is formed, the solution assuming a violet colour. When the acid is saturated this is converted, during the second stage of the operation, into the green dyestuff. The liquid becomes greenish-blue and the dyestuff separates in the form of small green needles. The intermediate product may be salted out from its solutions by means of potassium chloride, and after isolation in this manner may be reduced separately.—E. F.

Indigo white and its homologues; Production of chlorinated ——. Badische Anilin und Soda Fabrik. Fr. Pat. 358,864, Oct. 25, 1905. Under Int. Conv., Sept. 20, 1905.

Titanium; Manufacture of compounds of ——, *and their application in dyeing.* F. Erban. Chem.-Zeit., 1906, 30, 145—146.

In referring to the preparation of titanium hydroxide from rutile, the author gives an account of a method adopted about ten years ago, when this substance first attracted practical interest owing to its property of combining with dyestuffs. It consists in melting the ore with sodium hydroxide, lixiviating the mass with water, washing the residue free from alkali, dissolving it in hydrochloric acid, and treating the solution with alkali to precipitate the titanium as hydroxide. The product is freed from iron by adding sodium sulphide, washing the precipitate and treating it with sulphurous acid. It is then converted into the double oxalate of titanium and ammonium by treatment with oxalic acid and ammonium oxalate. Thirty parts of rutile containing 80—90 per cent. of titanic acid gave 120 parts of "oxalate."

By mordanting cotton with tannin and titanium previous to dyeing with basic dyestuffs, Kearns and Barnes (this J., 1897, 44) obtained fast colours. Dreher (this J., 1902, 1329), however, asserts that the dyeings on tanned leather with titanium salts are too pale in colour to be of practical value, a statement which is in disagreement with the author, who finds that these compounds act more efficiently than mordants consisting of tannin and antimony. For the production of yellow and orange shades fast to rubbing and washing, he recommends the use of a yellow bottom composed of tannin and titanium shaded with Auramine G or O, Acridine Orange or similar dyestuffs. Fast scarlets may be obtained by dyeing Safranine, Rhodamine, Acridine Red or Pyronine on the same bottom. Methylene Violet and Heliotrope give purple shades, Capri Blue, Thionine Blue, Nile Blue and Setoglaucine Green and Methylene Green olive colours. Titanium may also be applied as mordant on cotton in the form of hydroxide, but the colours obtained present no striking characteristics. When dyed on a tannin and titanium ground, the fastness of Gallocyanines is greatly increased.—D. B.

Sulphide dyestuffs as discharge colours on α-Naphthylamine Claret; Printing of ——. F. Iwanowski. Z. Farben-Ind., 1906, 5, 85—86.

A "fairly dark" blue discharge on α-Naphthylamine Claret may, it is stated, be produced with Immedial Indone R conc. and Rongalit C by means of the following printing colour: 80 grms. of Immedial Indone R conc., 40 grms. of caustic soda of 41° B., 40 grms. of glycerin, 370 grms. of alkaline thickening, 50 grms. of china clay, 260 grms. of Rongalit C, and 100 grms. of water. The alkaline thickening is prepared with 400 grms. of gum (1:1), 100 grms. of dextrin, 470 grms. of caustic soda (41° B.), and 30 grms. of turpentine. The goods are printed, steamed for 15 minutes in the absence of air, washed off in cold water, and soaped.—H. L.

Silk Yarn; Imitation ——. U.S. Customs Decision.

The United States Circuit Court of Appeals, January 16, 1906, held that artificial silk yarn, which in texture, quality and use resembles equally silk and cotton yarns, but being in fact produced from short fibre cotton, is not dutiable by similitude as "silk yarn" at 30 per cent. *ad valorem*. In view of the fact that the yarn consists of cellulose, the Court held it to be dutiable by similitude as "cotton yarn" under paragraph 302. This decision overrules both the United States Circuit Court and the Board of General Appraisers. The Treasury Department January 31, 1906, has acquiesced in this decision.

Chlorine; Action of silent electric discharge on ——. F. Russ. VII., page 264.

English Patents.

Steaming apparatus; Continuous open fabric ——. J. Wood, Ramsbottom, Lancs. Eng. Pat. 1547, Jan. 26, 1905.

The fabric is supported in the steaming chamber in festoons by rods or tubes carried on travelling chains. At the feeding end of the steam chamber the fabric is moved by a pair of nip rollers, which lower it in festoons between the supporting rods. These nip rollers may be readily disengaged and withdrawn by mechanism which is described. An improved festooning arrangement is described, consisting of a swinging guide moved periodically by each rod supporting the fabric as it is carried forward by the endless chain. The fabric may enter and leave at the bottom of the steaming chamber, to enable a greater density of steam to be more conveniently obtained. In any case the fabric enters over suitable steam-heated rollers. The steam may be produced by boiling water, in a well on the floor of the chamber, by means of closed or perforated steam pipes. The steam may be removed by down-take pipes ending near the top of the chamber, and arranged against the inner face of the walls, and similar up-take pipes for the steam may also be used. The rods or pipes supporting the fabric

can be partially rotated, so that all parts of the fabric may be completely exposed to the steam. This is effected by means of star-wheels attached to the ends of the rods, which engage on pins connected with cast-iron supports, on which the star-wheels slide.—E. F.

Shaded effects on fabrics; Method and apparatus for producing —— by padding. Farbwerke vorm. Meister, Lucius und Brüning, Hoechst on Maine, Germany. Eng. Pat. 10,195, May 15, 1905.

The invention relates to a padding process for printing fabrics with stripes of colour, so as to produce rainbow effects, and consists in applying the colours or mordants to a well wrapped roller of a padding machine, in such a manner that they merge into one another in unnterrupted gradations, and then transferring them by the pressure of a second roller to the fabric, which passes through the machine. For supplying the wrapped roller with the different solutions, endless bands are used, such as strips of felt, distributed in large numbers over the entire width of the machine, which, by rubbing against the roller, convey to it the colours from a series of vessels below. In another device the colour trough of the machine is divided into separate compartments, each containing one of the solutions, which are conveyed to the wrapped roller by a divided roller rotating in the trough, and having vertical slits to accommodate the partitions separating the different compartments.—D. B.

Galvanisers' waste products; Treatment of —— for the recovery of metal and the formation of other substances [Fireproofing solution and pigment]. S. E. Sanders. Eng. Pat. 4334, March 2, 1905. X., page 268.

Paper, textile fabrics or the like; Coating —— with viscose or mixtures thereof with pigments, and apparatus therefor. L. Lilienfeld and V. Tedesko. Eng. Pat. 5214, March 13, 1905. VI., page 263.

United States Patents.

Substances; Apparatus for degreasing ——. H. Roeske, Assignor to E. Printz, Philadelphia, Pa. U.S. Pat. 810,223, Jan. 16, 1906.

A tank, containing supports for the materials to be treated, is connected by two pipes with the top and bottom respectively of a condenser. Above the supports a propeller is mounted so as to be rotatable in opposite directions. Driven in one of these, it draws air or vapour from the tank to the upper pipe, when the materials are being treated, by a method of partial immersion, in the grease-solvent employed; moved in the opposite direction it forces air and the vaporised solvent through the lower pipe to the condenser, after the greater part of the solvent has been withdrawn from the tank.—E. B.

Potash leaching apparatus [for raw wool]. E. F. Bornhardt, Leisnig, Germany. U.S. Pat. 813,078, Feb. 20, 1906.

The raw wool is fed by rakes into a channel having a perforated bottom, secured over a reservoir containing the washing fluid, and divided into compartments. Sprinkler pipes, supplied by pumps with liquid from the reservoir, are arranged over the channel from the bottom of which the liquid is returned. The compartments into which the reservoir is divided have communicating openings through which the liquid flows from one to the other, the flow being controlled by the influx of water to the last compartment, in which the height of the liquid is regulated by a float. Pressing rollers receive the washed wool from the end of the channel.—E. S.

Fabrics; Process of ageing dyed ——. P. F. Vogel, St. Louis, Mo., Assignor to W. F. Calmore, Philadelphia, Pa. U.S. Pat. 810,312, Jan. 16, 1906.

Fabrics, which have been "subjected to the action of an oxidisable dye," are removed from the bath in which they have been immersed, and are exposed to air, the temperature of which is gradually first increased and then decreased until it has become normal, when they are removed to a chamber in which the ageing is completed, by continuously moving them through an atmosphere at or below the normal temperature.—E. B.

Fabrics; Process of oxidising ——. B. Cleff, Rauenthal, Germany, Assignor to the Susquehanna Silk Mills, New York. U.S. Pat. 810,394, Jan. 23, 1906.

Tissues, after being immersed in a bath containing a salt of aniline or an analogous compound and suitable oxidising compounds, are placed in a drying apparatus in which the oxidation is started. They are then introduced for a relatively short time into a highly heated and moist atmosphere in a closed chamber, where the oxidation is completed.—E. B.

Waterproof compound. O. H. Nowak, Assignor to E. Smith, Chicago, Ill. U.S. Pat. 809,731, Jan. 9, 1906.

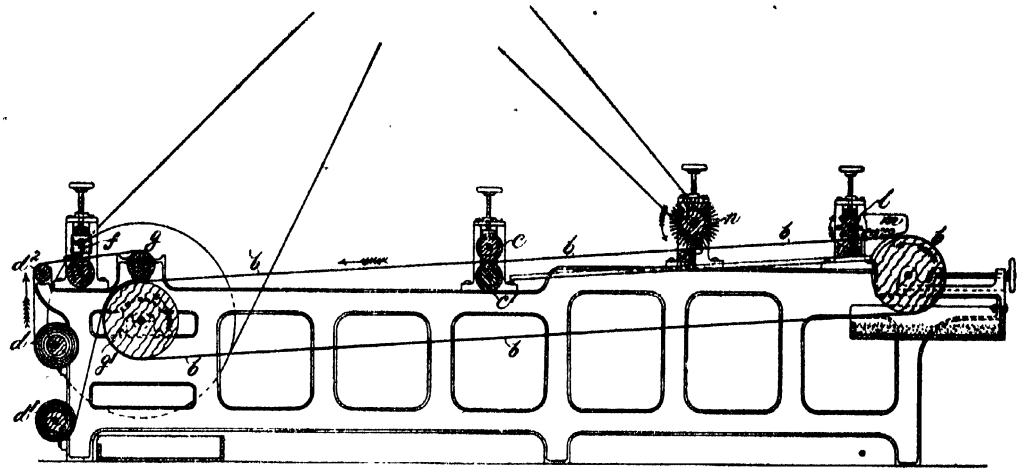
The claim is for a waterproofing mixture composed of a dihydroxynaphthylmethane compound, soluble in water, caseïn or other albuminoid or "adhesive," with or without a solvent for the latter, and a "colouring ingredient." The mixture is applied in aqueous solution.—E. B.

Materials or articles resistant to water and chemicals; Process for rendering ——. C. Kochmann and J. Kaufmann, Berlin. U.S. Pat. 813,218, Feb. 20, 1906.

See Eng. Pat. 16,744 of 1905; this J., 1905, 1225.—T.F.B.

French Patents.

Silk; Process of making brilliant threads similar to ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 350,442, Dec. 30, 1904.



See Eng. Pat. 28,733 of 1904; this J., 1905, 1299.—T.F.B.

Silk charged with tin compounds; Rendering —— resistant to destructive atmospheric agencies, and to perspiration. Soc. Anon. Coop. per la Stagionatura e l'Assaggio delle Sete ed Affini. Fr. Pat. 358,033, Sept. 26, 1905.

To render them more resistant to light, heat, "atmospheric agents," and to the soiling action of perspiration and chlorides, silk yarns and tissues, charged with tin compounds, are treated, after dyeing, with thiourea, quinol (hydroquinone), or a derivative of one of these compounds, quinol- (hydroquinone-) sulphonic acid being mentioned as especially suitable for the purpose. Silk tissues in the pure condition may also be "finished" with the same compounds to enable them to resist staining with chlorides and perspiration. The compounds are applied in solution, in the free state or in the form of salts. They possess the advantage, compared with thiocyanates (sulphocyanides), the use of which has been claimed for the same object (Eng. Pat. 25,728 of 1904; this J., 1905, 129), of not being susceptible to discoloration through contact with iron.—E. B.

Tissues; Machine for coating —— with finely divided materials. The Barnwell Machine Co., Ltd. Fr. Pat. 358,209, Oct. 2, 1905.

This apparatus, designed to effect the coating, in a continuous manner, of textile tissues with layers of finely divided materials, is constructed as follows:—An endless travelling apron, *b*, (*see* figure), driven in the direction indicated by the arrow, receives at a convenient point, *m*, in its course, the finely divided material with which the tissue is to be covered, which is deposited in a rough layer from a fluted cylinder, *l*, revolving in a box with a slit in its bottom. The material is evenly spread by a revolving brush, *n*, and is then pressed down upon the apron by two cylinders, c, c^1. The tissue to be coated is drawn from a roller *d*, to a roller, d^1, passing, on its way to the latter, successively over a roller, d^2, under a device, *f*, where a solution of indiarubber in solvent naphtha, or a similar adhesive solution, is applied to its surface, and, finally, between two pressure rollers, g, g^1. Here, the tissue and apron being brought into contact,

the layer of finely divided material is transferred from the latter to the prepared surface of the former.—E. B.

Textile tissues and wood; Use of non-hygroscopic compounds [Borate and phosphate of zinc] in rendering —— non-inflammable. H. Rose. Fr. Pat. 350,378, Dec. 7, 1904.

Textile tissues, wood and similar materials, are rendered non-inflammable by precipitating upon them zinc phosphate, zinc borate, or a mixture of both compounds. These are applied in ammoniacal solution, and become deposited in and upon the materials as the ammonia is volatilised during the process of drying the materials. The compounds employed, do not, it is stated, effloresce or absorb moisture from the air.—E. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

Paper, textile fabrics or the like; Coating —— with viscose or mixtures thereof with pigments, and apparatus therefor. L. Lilienfeld and V. Tedesko. Vienna. Eng. Pat. 5214, March 13, 1905.

In order to obtain uniform coatings on continuous supports, the paper, to which the viscose has been applied, is passed round a supporting roller, beside or above which revolves a distributing roller at a suitable speed in a direction contrary to that in which the paper is travelling, a doctor or scraper being applied to the periphery of the distributing roller to remove the excess of viscose taken from the coated surface by the roller.—D. B.

German Patents.

Dyeing leather; Process of ——. Act.-Ges. f. Anilinfabr. Ger. Pat. 164,504, June 5, 1904.

Leather is dyed by immersion in a solution of an aminoliphenylaminesulphonic acid and an oxidising agent, with or without addition of another dyestuff; the liphenylamine derivative is obtained by condensing *o*-nitrochlorobenzenesulphonic acid (NO_2:SO_3H:Cl = 1:3:4) with *m*-phenylenediamine, chloro-*m*-phenylenediamine, or *m*-toluylenediamine, and reducing the product. Grey-blue to blue-black shades are obtained on chrome leather, and grey-black on ordinary leather by this method.

—T. F. B.

Dyeing leather with sulphide dyestuffs; Process of ——. L. Cassella und Co. Ger. Pat. 163,621, June 18, 1904.

The present specification deals with a process of dyeing leather with sulphide dyestuffs without the use of an alkali sulphide as solvent, the solvent used in the present case is a solution of a formaldehyde-hydrosulphite compound.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 219.)

Arsenic from hydrochloric acid; Removal of ——, for use in the Marsh-Berzelius method. A. R. Ling and T. Rendle. XXIII., page 285.

Sodium carbonate and hydroxide; Densities of solutions of ——. R. Wegscheider. Monatsh. f. Chem. 1906, 27, 13—30.

The author has recalculated his formulæ (this J. 1905, 730), as he found that some of Lunge's densities were based on water at 4° C., and others not. He has corrected the latter accordingly, and the resulting formulæ are, for sodium carbonate:—

$$d_t = d_{(w)t} + (0{\cdot}053348 - 0{\cdot}0^4 5650t + 0{\cdot}0^6 3603t^2)N_t - (0{\cdot}0010962 - 0{\cdot}0^5 3583t + 0{\cdot}0^7 1873t^2)N_t^2$$

or

$$d_t = d_{(w)t} + (0{\cdot}0103829 - 0{\cdot}0^4 15527t + 0{\cdot}0^7 643t^2)P + (0{\cdot}0^4 3689 + 0{\cdot}0^6 1534t - 0{\cdot}0^8 865t^2)P^2,$$

and for sodium hydroxide

$$d_t = d_{(w)t} + (0{\cdot}0116027 - 0{\cdot}0^4 25111t + 0{\cdot}0^6 10222t^2)P - (0{\cdot}0^4 10817 - 0{\cdot}0^6 367 48t + 0{\cdot}0^8 2034t^2)P^2.$$

For discussion of the limits of agreement with observations the original must be consulted.—J. T. D.

Bismuth, Peroxides of ——. I. Oxidation of bismuth compounds by gaseous chlorine in presence of potassium hydroxide solution; the so-called "bismuthic acid" and the so-called "bismuth tetroxide dihydrate." A. Gutbier and R. Bünz. Z. anorg. Chem., 1906, 48, 162—184.

The authors made an exhaustive investigation on the action of gaseous chlorine on bismuth compounds in presence of potassium hydroxide solution, Deichler's experiments (this J., 1899, 616) being repeated. It was found that for the formation of peroxides of bismuth, the presence of alkali and its nature and concentration are of importance. It is only in presence of potassium hydroxide that compounds are formed, which yield yellow to red coloured products on treatment with concentrated nitric acid. It was found that those products which yielded the largest quantity of the red-coloured peroxide on treatment with nitric acid, contained the greatest proportion of active oxygen. Notwithstanding numerous attempts, the authors were unable, by the action of

chlorine on bismuth compounds, in presence of potassium hydroxide, to obtain uniform products or to isolate from the reaction-products definite chemical compounds. They are, therefore, unable to confirm previous statements as to the existence of "bismuthic acid" and "bismuth tetroxide dihydrate."—A. S.

Bismuth; Peroxides of ——. *II. Oxidation of bismuth oxide by electrolytic chlorine in presence of potassium hydroxide, and the so-called "potassium bismuthate."* A. Gutbier and R. Bünz. Z. anorg. Chem., 1906, **48**, 204—206.

Deichler, in 1899 (this J., 1899, 616), stated that the hitherto unknown "potassium bismuthate, $KBiO_3$," is formed when a mixture of bismuth oxide, potassium hydroxide solution, and potassium chloride is electrolysed. The authors have repeated Deichler's experiments, but have never succeeded in obtaining a homogeneous substance; the product of the electrolysis is not a "potassium bismuthate," but a mixture of compounds, as previously described (see preceding abstract). On treating the product with hot, concentrated nitric acid, there is obtained not "bismuthic acid" as stated by Deichler, but a mixture of peroxides of bismuth.—A. S.

Phosphorus sulphides. H. Giran. Comptes rend., 1906, **142**, 398—400.

The author heated to a high temperature in sealed tubes, mixtures in various proportions of sulphur and phosphorus, and determined their solidifying points. There were four maxima on the resulting curve, at 167°, 296°, 272°, and 314° C., corresponding to the four compounds P_4S_3, P_2S_3, P_2S_5, and PS_4, and four minima indicating eutectics near in composition to P_2S, PS, PS_2, and PS_3.—J. T. D.

Sulphur, sulphate; The system ——. K. Brückner. Monatsh. f. Chem., 1906, **27**, 49—58.

The author has systematically examined the action of sulphur on metallic sulphates, when heated with them in a covered porcelain crucible, or when its vapour is passed over the red-hot salts. The alkali and alkaline-earth sulphates all yield mixtures of sulphide, thiosulphate and polysulphide, probably formed by the following reactions:—

$2M_2SO_4 + S = 2M_2SO_3 + SO_2$; $4M_2SO_3 = M_2S + 3M_2SO_4$;
$M_2SO_3 + S = M_2S_2O_3$; $4M_2S_2O_3 = M_2S_5 + 3M_2SO_4$.

The sulphates of magnesium, beryllium, and aluminium practically do not react with sulphur. The sulphates of other metals all yield sulphides, but in some cases the sulphide and oxide react and yield the metal (bismuth, lead, antimony), and in some cases the oxide itself is formed (uranium).—J. T. D.

Chlorine; Action of the silent electric discharge on ——. F. Russ. Monatsh. f. Chem., 1905, **26**, 627—646.

Kellner, in 1891, patented a process for increasing the bleaching effect of chlorine by subjecting it to the action of the silent electric discharge (Eng. Pat. 22,438 of 1891; this J., 1892, 354). Mellor, in 1904, found that chlorine, which had been subjected to the electric discharge, showed a shorter induction period in the reaction between hydrogen and chlorine under the influence of light than ordinary chlorine (see Chem. Soc. Proc., 1904, **20**, 140, 196). The author has investigated this "activation" of chlorine, using as a basis of measurement the action of the chlorine on benzene. It was found that the effect is due to the combined action of ultra-violet light rays and the silent electric discharge, and is much less pronounced if one of these factors be suppressed. The rate of "activation" of the chlorine is greater in a quartz vessel than in a glass one, the former being penetrated more readily by the ultra-violet rays. Chlorine dried by means of sulphuric acid or phosphorus pentoxide is not so susceptible to the effect of the electric discharge or ultra-violet rays as ordinary moist chlorine. The active chlorine retains its activity for long periods at the ordinary temperature, but is rendered inactive by heating, by the passage of electric sparks, or by treatment with water. (See also Fr. Pat. 352,198 of 1905; this J., 1905, 892.)—A. S.

French Patent.

Cupric chloride; Manufacture of ——, *and its transformation into cupric sulphate.* G. Darier. Fr. Pat. 350,421, Dec. 22, 1904.

Copper turnings and water are subjected in a closed stone vessel (having the usual inlets and outlets) to the action of chlorine gas. The action is feeble at first, but becomes vigorous owing to the formation of cuprous chloride, which quickly absorbs chlorine, with rise of temperature, to form the cupric salt, the solution of which is withdrawn and crystallised. By heating the crystallised cupric chloride with strong sulphuric acid, in a suitable vessel connected to a receiver for collection of the hydrochloric acid evolved, cupric sulphate is formed.—E. S.

German Patents.

Hydrochloric acid containing arsenic; Process for the purification of ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 164,355, April 15, 1904.

The process consists in treating the impure acid with compounds of vanadium dioxide. When an indigo blue, sulphuric acid or hydrochloric acid solution of vanadium dioxide is added to hydrochloric acid containing arsenic, metallic arsenic is immediately precipitated, especially if the acid be warm. The blue colour of the vanadium dioxide compounds changes to the green of vanadium sesquioxide compounds. In practice the hydrochloric acid gas from the salt-cake pans or furnaces is led through a concentrated hydrochloric acid solution of vanadium dioxide contained in an earthenware vessel, perforated plates being provided to ensure intimate contact between liquid and gas. When the vanadium solution is exhausted, the separated arsenic is filtered off, and the vanadium sesquioxide re-converted into vanadium dioxide electrolytically.—A. S.

Sulphuric acid obtained by the contact process; Method for the clarification and purification of ——. M. Liebig. Ger. Pat. 164,722, July 24, 1904.

Sulphuric acid manufactured by the contact process is dark-coloured, probably owing to organic impurities. According to this invention the acid is treated at the ordinary temperature with a metallic peroxide, such as lead peroxide or barium dioxide, and then passed through a suitable filter, *e.g.*, a sand-filter.—A. S.

Carnallite and other haloid double salts of the alkaline-earths; Apparatus for the continuous treatment of fused —— by electrolysis. E. Haag and F. Glinicke. Ger. Pat. 163,413, Jan. 20, 1904. XI*A*., page 271.

Sodium chromate; Electrolytic manufacture of —— from chrome iron ore. Chem. Fabr. in Billwärder vorm. Heil und Sthamer A.-G. Ger. Pat. 163,541, Feb. 28, 1904. XI*A*., page 271.

Ammonia-soda manufacture; Process for the [electrolytic] treatment of the waste solutions of —— with recovery of brine for use over again. A. Riedel. Ger. Pat. 164,726, March 8, 1904. XI*A*., page 271.

Cyanamide; Process for preparing —— from sodium-cyanamide solutions. Deutsche Gold- und Silberscheide-Anstalt vorm. Roessler. Ger. Pat. 164,724, March 17, 1904.

SODIUM-CYANAMIDE solution is mixed with sulphuric acid in sufficient quantity to render it neutral or very faintly acid, the concentrations of the solution and of the acid being so adjusted that the total quantity of water present is not greater than that which can be fixed by the sodium sulphate produced, to form Glauber's salt. The cake of Glauber's salt and cyanamide is extracted with absolute alcohol or ether, and the cyanamide is recovered from the solution by crystallisation. A. S.

Sulphuretted hydrogen and finely divided sulphur; Process of Producing ——. P. Mochalle. Ger. Pat. 164,322, April 12, 1904.

SUGAR (100 grms.) is melted with sulphur (5 to 10 grms.), and heated for ten minutes; the melt is allowed to cool, and is then broken up. On treatment with water, hydrogen sulphide is evolved, and sulphur, in a finely divided state, separates. The melt may, if desired, be dissolved in sodium carbonate solution, evaporated to dryness, and then treated with water.—T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 219.)

Potters' materials; Plasticity of ——. J. W. Mellor. Trans. Eng. Ceramic Soc., 1905-6, **5**, 72—73.

THE author heated separately ground felspar and ground Cornish stone with water, under great pressure (below 75 atmospheres) in sealed tubes for a few days, at from 250° to 300°. Four important facts were noticed. First, the plasticity of the materials was increased, and the new plasticity was not of the pseudo or temporary character produced by the addition of foreign materials like soft soap, tannin, gums, &c. Second, the outlines of the particles, under the microscope, had lost their clear, sharp definition, and become more or less irregular and blurred. Cushman found the same difference in a less degree between felspar ground in cold water and felspar ground dry. Third, the outlines could be more readily stained with Safranine or with Malachite Green than before the action. Fourth, the water in which the materials were heated, after the action, contained a quantity of soluble salts. This agrees with an experiment of Daubrée's, in which a solution of potassium silicate was obtained by the prolonged action of water upon ground felspar.

The author has applied the same treatment to other bodies with the following results:—With ground flint, there was little, if any, perceptible difference before and after treatment. The plasticity of china clay was slightly improved, while ground earthenware and china pitchers "became relatively quite plastic." He points out that only those materials were made appreciably plastic that contain alkalis in combination with silica and alumina, and considers that liquid water and not steam is the potent agent. The process also works better if the water is changed, probably because this prevents the recombination of the soluble materials with the bodies from which they have been removed.—W. C. H.

Porcelain body and its toughness; Relation between the composition of a ——. E. Ogden. Trans. Amer. Ceramic Soc., 1905, **7**, 370—396.

A LARGE number of mixtures were made from the following raw materials:—Brandywine felspar, Golding's flint, English ball clay, English china clay, and English whiting. All the porcelains were burnt at the temperature of cone 10. It was found that an increase in the RO fluxes (alkalis and alkaline-earths) increased the translucency and fineness of structure. The greatest toughness was shown with 0·25 RO, the toughness decreasing as the RO fluxes increase; if part of the RO consisted of lime, an increase in stoniness and toughness was noted. For the same RO content, an increase in clay increased the fineness of structure and degree of vitrification, but rendered the porcelain more brittle.—A. G. L.

China bodies in the enamel kiln; Cause and prevention of the brown stain in ——. B. Moore. Trans. Eng. Ceramic Soc., 1905—6, **5**, 37—41.

BROWN patches and blotches sometimes appear when the ware is fired in the enamel kiln, although when taken from both the biscuit and glost ovens it may have looked sound and good (often, however, of a greenish tint). The defect appears to have first occurred in the Longton district about 25 years ago. Chemical analysis of defective pieces did not indicate anything abnormal to account for the stains. The author took as a normal china body:—44 parts of bone ash, 30 of stone, and 26 of clay. Experiments with every variety of bone procurable, did not show the cause of the stains, and with a dry buff variety of stone, green-coloured ware was always obtained, and the tint was improved, towards white, by an increase of this constituent. Brown-stained ware was, however, always obtained when the stone was decreased, and the clay increased, for example, with a mixture of bone, 44; stone, 23·5; and clay, 32·5 parts.

The author discusses three factors that influenced the introduction of such a body composition, *viz.*:—1. The use of a very dry stone. 2 Too much clay compared with stone. 3. An improper system of mixing—the most important of all.

The use of a very dry stone became prevalent about 30 years ago, and, as the china body seemed deficient in plasticity, an increased amount of clay was employed, and a body of the type: 44 parts of bone, 28 of stone, and 28 of clay came to be used. With regard to mixing, the change from the slip kiln to the press, diminished the chances of good mixing which arose in the case of the slip kiln. Further, in many cases, the second "ark" in the slip house is not large enough to hold the whole of the charge of bone, stone and clay, fed into the first ark or "rough pot," so that if any material is taken out of the second ark before all the charge in the first has been "blunged," the slip cannot be uniform.

The author considers that the green colour is due to a ferrous phosphate, which changes in the kiln to a ferric phosphate. From some experiments made with mixtures of bone ash and silica and fired at an "easy" and a full heat, and from the losses in weight after firing, it was found that the phosphoric acid displaced by silica, appeared to distribute itself among the bases present, when the materials were well mixed, and not fired in layers. Consequently this distribution would be most likely to occur in pressed ware, which is said to be nearly always the case in practice; pressed ware shows a darker colour than cast ware.—W. C. H.

Glazes; Cornwall stone and felspar in raw lead ——. L. B. Coulter. Trans. Amer. Ceramic Soc., 1905, **7**, 356—369.

IT is found that raw lead glazes shrink less in drying and burning when Cornwall stone is used as an ingredient than with felspar, the reason being that when the latter is used, additional alumina in the form of clay must be supplied, and that the clay has a high drying and burning shrinkage. If the Cornwall stone or felspar is used merely as a source of alkali, the first produces the more fusible glaze for a low requirement of alkali, whilst, if much alkali is needed, felspar gives a more fusible glaze. This arises from the

fact that in the Cornwall stone the alkaline-earths and alkalis are already more or less combined with the alumina and silica, and hence fuse more readily than is the case with felspar, to which additional silica and alumina must be added; on the other hand, if much alkali is wanted, the quantities of alumina and silica added, if it is introduced as Cornwall stone, are so high as to give a refractory glaze. The cost of Cornwall stone glazes exceeds that of felspar glazes by about 2 or 3 per cent. (in the United States).—A. G. L.

Glazes; Solubilities of metallic oxides in ——. I. and II. C. E. Ramsden. Trans. Eng. Ceramic Soc., 1905–6, **5**, 1—23.

GLAZES are mixtures of various silicates and borates and cannot be regarded as definite chemical compounds. The physical characteristics of a glaze are those of a solid solution. The section of a piece of glazed ware shows three layers—(*a*) an outer skin of clear glaze, (*b*) an intermediate layer consisting of glaze and body mixed in varying proportions and (*c*) the body itself. As in the case of the aqueous solution of a salt, so in the case of a glaze to which an excess of a metallic oxide has been added; after cooling, there is no evidence at present as to what are the relative proportions of oxide which has been dissolved and then again separated, and oxide which has been undissolved all through the experiment. Further, in the case of glazes, the colouring matter which has been dissolved may separate, not as free oxide, but combined with some constituents of the glaze. The amount of metallic oxide that a glaze can take up whilst still remaining clear depends upon (*a*) the chemical composition of the glaze, (*b*) the physical properties of the glaze, such as viscosity, fluidity, &c., (*c*) the physical condition of the chromatic oxide, (*d*) the temperature to which it is subjected, and (*e*) the rate of cooling.

The object of the investigation was to gain information on these points, and also to note the effect of variations of the glaze formula, and of temperature on the colour obtained; the effect of variations of the amount of metallic oxide used, and what volatilisation of it, if any, occurred. Twelve series of glazes, maturing at about 1050° C., were made, the proportions of the constituents being varied in the individual members of each series. The glazes ranged from the comparatively simple mixtures of litharge and silica to more complex forms containing sodium carbonate, lime, boric acid, &c.; wherever possible they were compounded "raw," only those containing alkalis and boric acid being fritted. Definite percentages of oxides of nickel, manganese, chromium, copper, iron, cobalt and uranium were introduced (only the first and second are considered in this paper). At least three different mixtures of each oxide were made with each glaze, and fired at 1000°, 1050°, and 1100° C.; the cooling curves are given for each temperature, the last being steeper than either of the others. All the trials with plumbic glazes were fired under fire-clay boxes, smeared with a particular glaze ($1{\cdot}0PbO$; $0{\cdot}1Al_2O_3$; $1{\cdot}2SiO_2$); and the leadless trials under boxes smeared with a glaze of the following composition:—

$$\left.\begin{matrix}0{\cdot}6Na_2O\\0{\cdot}4CaO\end{matrix}\right\}\ \left\{\begin{matrix}0{\cdot}1Al_2O_3\\0{\cdot}5B_2O_3\end{matrix}\right.\ \left\{\begin{matrix}2{\cdot}5SiO_2\\\end{matrix}\right.$$

I. Nickel oxide.—The solubility of this oxide, in glazes maturing at a temperature not exceeding 1100° C., never exceeds 1 per cent. of the protoxide, but varies with the composition of the glaze. In lead glazes the amount of nickel oxide dissolved can be increased by raising the acidity to 1·5 molecular part, by increasing the content of silica, and also in the same way with alkali glazes, and an increase of temperature in both cases seems to increase the solubility. In both lead and alkali glazes the solubility is increased by substituting boric acid for silica, while maintaining the high acidity; but the molecular ratio of silica to boric acid must never be less than 2 to 1, or opalescence will occur, even with moderately quick cooling. The solubility is also increased by the addition of a small quantity of tin oxide, not exceeding 2 per cent., to a lead glaze; the increased solubility is probably due to the solution of a small quantity of tin oxide in the glaze, the acidity of which is thus increased. In both lead and alkali glazes an increase in alumina decreases the solubility of the nickel oxide, and raising the firing temperature does not counteract its effect; on the other hand, devitrification may occur if the alumina content is decreased too much. To ensure solubility in the absence of R_2O bases, the PbO must not be less than 0·7 of a molecular part; if the PbO exceeds that amount, the solubility may be increased by replacing a portion of it by other RO bases, such as lime, zinc oxide, and, in some cases, magnesia. Though no single oxide is as powerful a solvent as lead oxide, yet a mixture of bases is better than any one alone. Zinc oxide increases the solubility in a very distinct way, and may replace lead oxide up to 0·2 of a molecular part. The solubility is also increased by replacing lead oxide and other RO bases by alkalis.

It was found from the trials that the best results were obtained at a firing temperature of 1050°; in most cases at 1100° C. dark spots occurred, due to local separation of the nickel oxide. These separations are less likely to occur when the rate of cooling is rapid. With lead glazes the colour was straw-brown, except when magnesia was present, when the colour became distinctly green, especially at 1100° C. The alkali glazes were grey, but an increase of nickel oxide, alumina, or boric acid in them converted the colour to brown. No volatilisation of nickel oxide was detected in these experiments.

II. Manganese oxide.—In this set of experiments, manganese carbonate was used in amounts equivalent to 1, 2, and 4 per cent of the monoxide, and with the glazes used, the amounts dissolved varied between these extremes, at temperatures below 1100° C. The solubility is increased by altering the composition of the glaze in the same ways as described for nickel oxide, with two exceptions. Unlike nickel oxide, the solubility of manganese oxide is not affected by the addition of alumina to an alkali glaze. In both the oxides considered, the decrease in solubility that accompanies the increase of alumina, may be due to the increased viscosity of the glaze by alumina. In the case of manganese oxide, the replacement of part of the silica by boric acid does not increase the solubility of the oxide. Though firing at 1050° increased the amount of oxide dissolved, better colours were obtained at 1000° C., and, as before, coloured separations are less likely to occur when the rate of cooling is rapid. The colour of the glazes with manganese oxide, generally claret-brown, is considerably modified by alteration in the composition of the glazes, and of the firing temperature. An increase of silica, or the presence of litharge, zinc oxide or lime, gave pink tints, but alumina and boric acid gave brown tints. The only indication of volatilisation was that some of the glazes, containing 4 per cent. of manganese monoxide, were coated with a film, apparently of condensed manganese oxide.

The colouring matter is the most expensive component of "majolica" glazes; hence these experiments have a practical value, in that they show the conditions necessary for the solubility of the oxide, and the conditions that affect the colour, which is generally better when the solubility is complete, whilst many defects arise from the separation in the glaze of colouring compounds and from supersaturation.—W. C. H.

[Glass] Beakers. U.S. Customs Decision, Jan. 22, 1906.

BEAKERS used for chemical purposes are dutiable at 60 per cent. *ad valorem* as "blown glass ware" under paragraph 100 of the present tariff. [T.R.] R. W. M.

Glassware; Chemical ——. U.S. Customs Decision, Jan. 29, 1906.

PHOTOGRAPHIC baths and glass tubing are dutiable at 60 per cent. *ad valorem* under paragraph 100, as "blown glassware," and evaporating dishes, the edges of which had been ground and polished, are dutiable at the same rate and the same paragraph as "ground glassware." [T.R.]

ENGLISH PATENT.

Clay or similar materials; Drying of various substances, such as ——. T. M. Stocker, St. Austell, Cornwall. Eng. Pat. 2102, Feb. 2, 1905.

THE invention consists essentially in securing a more even heating of the drying chamber by arranging that the air necessary for the combustion of the producer or other gas in the flues below the drying chamber, enters by a number of ports distributed along these flues. The flues may be constructed according to the inventor's Eng. Pat. 2097 of 1905 (this J., 1906, 219).—A. G. L.

FRENCH PATENT.

[*Ceramic objects.*] *Use in the ceramic industry of earths occurring in alluvial deposits, either naturally of special composition, or else artificially mixed.* J. Dessane. First Addition, dated Sept. 27, 1905, to Fr. Pat. 354,201, May 9, 1905 (this J., 1905, 1110).

IN order to do away with the grinding of the worked clay, as described in the main patent, which grinding is necessary only to incorporate uncombined particles of iron oxide and of silica with the mass, the clay is purified from these particles by levigation as usual. The resulting loss of about 15 per cent. of the material is more than counterbalanced by the gain due to avoiding grinding, requiring a lower temperature for the burning and giving higher value to the finished article.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 220.)

Bauxite; Advantages of —— as a refractory material. A. J. Aubrey. Eng. and Mining J., 1906, **81**, 217–218.

THE advantages of bauxite as a refractory material for lining open-hearth furnaces, rotary cement kilns and lead-refining furnaces are discussed. It is stated that a lining of bauxite, 6 in. thick, in a cement kiln was in good condition after ten months' continuous service, and that, as a lining for lead-refining furnaces, bauxite lasts from five to six times as long as firebrick.—A. S.

UNITED STATES PATENTS

Dust in roads; Process for the prevention and laying of ——. W. M. Sandison, Ayton, Scotland, Assignor to H. G. McKerrow, Newton, Mass. U.S. Pat. 813,389, Feb. 20, 1906.

SEE Eng. Pat. 18,904 of 1904; this J., 1905, 443.—T. F. B.

Cement-kiln; Oscillating ——. B. E. Eldred, Bronxville, N.Y., Assignor to Combustion Utilities Co., New York, N.Y. U.S. Pat. 812,834, Feb. 20, 1906.

THE cement-kiln consists of an inclined barrel, lined with refractory material, of greater lateral than vertical diameter, and which can be automatically rocked. The kiln tapers from the lower end, at which there is arranged an exterior furnace with grate and ash-pit, to the higher end, which communicates with a stack and feed for the raw material. A conduit fitted with a fan-blower is also arranged so as to return products of combustion from the stack end to the ash-pit below the grate.—A. G. L.

Cement; Production of ——. B. Grau, Kratzwieck, Germany. U.S. Pat. 813,965, Feb. 27, 1906.

SEE Fr. Pat. 343,152 of 1904; this J., 1904, 985.—T. F. B.

FRENCH PATENTS.

Building material; Silico-calcareous ——. C. de la Roche. Fr. Pat. 350,340, Nov. 23, 1904.

SEE Eng. Pat. 25,884 of 1904; this J., 1905, 1233.—T.F.B.

Textile tissues and wood; Use of non-hygroscopic compounds [Borate and phosphate of zinc] in rendering —— non-inflammable. H. Rose. Fr. Pat. 350,378, Dec. 7, 1904. V., page 263.

Wood; Process of caulking —— during impregnation or dyeing. G. Kron. Fr. Pat. 358,602, Oct. 17, 1905. Under Int. Conv., Jan. 9, 1905.

SEE Eng. Pat. 20,791 of 1905; this J., 1906, 122.—T.F.B.

Fireproofing combustible materials; Solution for ——. The Fire-Resisting Corporation, Ltd. Fr. Pat. 358,736, Oct. 21, 1905. Under Int. Conv., March 13, 1905.

SEE Eng. Pat. 5209 of 1905; this J., 1906, 182.—T. F. B.

Stone and pavements; Manufacture of artificial —— E. Philippe. Fr. Pat. 350,439. Dec. 30, 1904.

FOR making artificial stone, 1000 litres of sea-sand, and 500 of calcined magnesia are mixed with 75 litres of a magnesium chloride solution at 34° B., containing 1 per cent. by weight of calcined alum, 2 of zinc carbonate, 3 of lead acetate, and 2 of mercuric chloride, and with 25 litres of a solution of zinc sulphate at 12° B. For pavements, wall-facings, &c., 25 litres of soft sawdust, 2 of crushed stone, &c., and 9 of magnesia are mixed with sufficient of the above two liquids to give a semi-liquid paste.—A. G. L.

Furnace with generator gas as fuel, for roasting limestone, dolomite and other analogous materials. E. Schmatolla. First Addition, dated Sept. 26, 1905, to Fr. Pat. 352,549, Feb. 17, 1905.

THE improvement in the furnace described in the main patent (compare Eng. Pat. 4245 of 1905; this J., 1905, 925) consists in distributing the gas by bringing the latter through a channel to the middle of the base of the furnace, the channel then dividing into others arranged in a cross, star or T-form. These channels end in the ascending ones. A portion of the gas is introduced into the interior of the furnace by a central channel ascending directly from the middle of the base of the furnace.—B. N.

Silicon carbide; Process of making solid moulded forms of ——. Gebr. Siemens und Co. Fr. Pat. 358,599, Oct. 17, 1905.

SEE Eng. Pat. 21,347 of 1905; this J., 1906, 122.—T. F. B.

Cement; Manufacture of impermeable and acid-resisting ——. R. Liebold. First Addition, dated Oct. 5, 1905, to Fr. Pat. 345,421, Aug. 8, 1904 (this J., 1905, 31).

IN the present modification the impregnation of the burnt but unground cement with a solution of a fatty material is made whilst the cement is still warm (at about 50° C.), the water used for dissolving the fatty material being quickly driven off by the heat contained in the cement, which latter can consequently be ground immediately after the impregnation. Suitable fatty materials are ½ per cent. of Japan wax or ¼ per cent. of fatty acids (stearine) dissolved in a hot alkaline solution.—A. G. L.

X.—METALLURGY.

(*Continued from page* 222.)

Blende and precipitated zinc sulphide; Roasting of ——. J. Krutwig. Congrès de Chim. Pharm., Liège, Sec. II., 419.

WHEN blende or precipitated zinc sulphide is heated in a stream of air, decomposition begins about 450° C. with the former, and 327° C. with the latter; in a stream of oxygen the respective temperatures are 366° and 280° C. At temperatures above these, the decomposition of the precipitated sulphide is always more rapid, and proceeds farther than that of blende, and is, indeed, more rapid in air than that of blende in oxygen. In no case is the proportion of sulphate formed considerable; its absolute amount increases with the temperature, though but slightly (to 6—8 per cent.), but the ratio of sulphate to oxide is smaller at high than at low temperatures. This is

fact that in the Cornwall stone the alkaline-earths and alkalis are already more or less combined with the alumina and silica, and hence fuse more readily than is the case with felspar, to which additional silica and alumina must be added; on the other hand, if much alkali is wanted, the quantities of alumina and silica added, if it is introduced as Cornwall stone, are so high as to give a refractory glaze. The cost of Cornwall stone glazes exceeds that of felspar glazes by about 2 or 3 per cent. (in the United States).—A. G. L.

Glazes; Solubilities of metallic oxides in ——. I. and II. C. E. Ramsden. Trans. Eng. Ceramic Soc., 1905–6, **5**, 1—23.

GLAZES are mixtures of various silicates and borates and cannot be regarded as definite chemical compounds. The physical characteristics of a glaze are those of a solid solution. The section of a piece of glazed ware shows three layers—(*a*) an outer skin of clear glaze, (*b*) an intermediate layer consisting of glaze and body mixed in varying proportions and (*c*) the body itself. As in the case of the aqueous solution of a salt, so in the case of a glaze to which an excess of a metallic oxide has been added; after cooling, there is no evidence at present as to what are the relative proportions of oxide which has been dissolved and then again separated, and oxide which has been undissolved all through the experiment. Further, in the case of glazes, the colouring matter which has been dissolved may separate, not as free oxide, but combined with some constituents of the glaze. The amount of metallic oxide that a glaze can take up whilst still remaining clear depends upon (*a*) the chemical composition of the glaze, (*b*) the physical properties of the glaze, such as viscosity, fluidity, &c., (*c*) the physical condition of the chromatic oxide, (*d*) the temperature to which it is subjected, and (*e*) the rate of cooling.

The object of the investigation was to gain information on these points, and also to note the effect of variations of the glaze formula, and of temperature on the colour obtained; the effect of variations of the amount of metallic oxide used, and what volatilisation of it, if any, occurred. Twelve series of glazes, maturing at about 1050° C., were made, the proportions of the constituents being varied in the individual members of each series. The glazes ranged from the comparatively simple mixtures of litharge and silica to more complex forms containing sodium carbonate, lime, boric acid, &c.; wherever possible they were compounded "raw," only those containing alkalis and boric acid being fritted. Definite percentages of oxides of nickel, manganese, chromium, copper, iron, cobalt and uranium were introduced (only the first and second are considered in this paper). At least three different mixtures of each oxide were made with each glaze, and fired at 1000°, 1050°, and 1100° C.; the cooling curves are given for each temperature, the last being steeper than either of the others. All the trials with plumbic glazes were fired under fire-clay boxes, smeared with a particular glaze ($1{\cdot}0PbO$; $0{\cdot}1Al_2O_3$; $1{\cdot}2SiO_2$); and the leadless trials under boxes smeared with a glaze of the following composition:—

$$\left.\begin{matrix}0{\cdot}6Na_2O\\0{\cdot}4CaO\end{matrix}\right\}\ \left\{\begin{matrix}0{\cdot}1Al_2O_3\\0{\cdot}5B_2O_3\end{matrix}\right.\ \left\{\begin{matrix}2{\cdot}5SiO_2\\\end{matrix}\right.$$

I. Nickel oxide.—The solubility of this oxide, in glazes maturing at a temperature not exceeding 1100° C., never exceeds 1 per cent. of the protoxide, but varies with the composition of the glaze. In lead glazes the amount of nickel oxide dissolved can be increased by raising the acidity to 1·5 molecular part, by increasing the content of silica, and also in the same way with alkali glazes, and an increase of temperature in both cases seems to increase the solubility. In both lead and alkali glazes the solubility is increased by substituting boric acid for silica, while maintaining the high acidity; but the molecular ratio of silica to boric acid must never be less than 2 to 1, or opalescence will occur, even with moderately quick cooling. The solubility is also increased by the addition of a small quantity of tin oxide, not exceeding 2 per cent., to a lead glaze; the increased solubility is probably due to the solution of a small quantity of tin oxide in the glaze, the acidity of which is thus increased. In both lead and alkali glazes an increase in alumina decreases the solubility of the nickel oxide, and raising the firing temperature does not counteract its effect; on the other hand, devitrification may occur if the alumina content is decreased too much. To ensure solubility in the absence of R_2O bases, the PbO must not be less than 0·7 of a molecular part; if the PbO exceeds that amount, the solubility may be increased by replacing a portion of it by other RO bases, such as lime, zinc oxide, and, in some cases, magnesia. Though no single oxide is as powerful a solvent as lead oxide, yet a mixture of bases is better than any one alone. Zinc oxide increases the solubility in a very distinct way, and may replace lead oxide up to 0·2 of a molecular part. The solubility is also increased by replacing lead oxide and other RO bases by alkalis.

It was found from the trials that the best results were obtained at a firing temperature of 1050°; in most cases at 1100° C. dark spots occurred, due to local separation of the nickel oxide. These separations are less likely to occur when the rate of cooling is rapid. With lead glazes the colour was straw-brown, except when magnesia was present, when the colour became distinctly green, especially at 1100° C. The alkali glazes were grey, but an increase of nickel oxide, alumina, or boric acid in them converted the colour to brown. No volatilisation of nickel oxide was detected in these experiments.

II. Manganese oxide.—In this set of experiments, manganese carbonate was used in amounts equivalent to 1, 2, and 4 per cent of the monoxide, and with the glazes used, the amounts dissolved varied between these extremes, at temperatures below 1100° C. The solubility is increased by altering the composition of the glaze in the same ways as described for nickel oxide, with two exceptions. Unlike nickel oxide, the solubility of manganese oxide is not affected by the addition of alumina to an alkali glaze. In both the oxides considered, the decrease in solubility that accompanies the increase of alumina, may be due to the increased viscosity of the glaze by alumina. In the case of manganese oxide, the replacement of part of the silica by boric acid does not increase the solubility of the oxide. Though firing at 1050° increased the amount of oxide dissolved, better colours were obtained at 1000° C., and, as before, coloured separations are less likely to occur when the rate of cooling is rapid. The colour of the glazes with manganese oxide, generally claret-brown, is considerably modified by alteration in the composition of the glazes, and of the firing temperature. An increase of silica, or the presence of litharge, zinc oxide or lime, gave pink tints, but alumina and boric acid gave brown tints. The only indication of volatilisation was that some of the glazes, containing 4 per cent. of manganese monoxide, were coated with a film, apparently of condensed manganese oxide.

The colouring matter is the most expensive component of "majolica" glazes; hence these experiments have a practical value, in that they show the conditions necessary for the solubility of the oxide, and the conditions that affect the colour, which is generally better when the solubility is complete, whilst many defects arise from the separation in the glaze of colouring compounds and from supersaturation.—W. C. H.

[Glass] Beakers. U.S. Customs Decision, Jan. 22, 1906.

BEAKERS used for chemical purposes are dutiable at 60 per cent. *ad valorem* as "blown glass ware" under paragraph 100 of the present tariff. [T.R.] R. W. M.

Glassware; Chemical ——. U.S. Customs Decision, Jan. 29, 1906.

PHOTOGRAPHIC baths and glass tubing are dutiable at 60 per cent. *ad valorem* under paragraph 100, as "blown glassware," and evaporating dishes, the edges of which had been ground and polished, are dutiable at the same rate and the same paragraph as "ground glassware." [T.R.]
R. W. M.

the boiling being prolonged, or more flux added, if found necessary, until a proper fireproofing solution is obtained. This is then drawn off, and the heating of the residue continued until the latter is dry, when it is "bruised" to a powder, from which metallic zinc is removed by sifting. The final residue, consisting of zinc oxide and chloride, &c., is used as a fireproof paint. The addition of lime may be omitted if the solution obtained is sufficiently clear without it.—A. G. L.

Slag; Apparatus for disintegrating ——. G. K. Hamfeldt, Beaver, Pa., U.S.A. Eng. Pat. 22,932, Nov. 8, 1905.

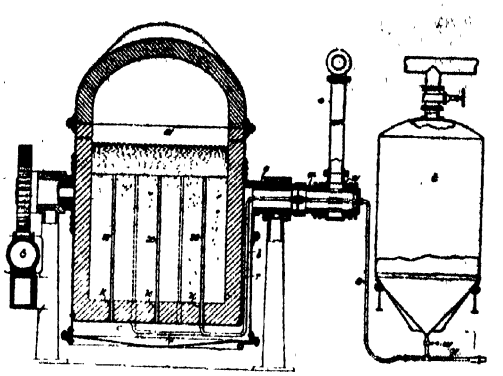
THE molten slag while flowing in a tube or conduit is subjected to the action of a stream of water moving in the same direction, whereby it is thrown laterally outwards against the walls of the tube and completely disintegrated. —J. H. C.

UNITED STATES PATENTS.

Iron ore; Process of reducing ——. G. M. Westman, New York. U.S. Pat. 812,247, Feb 13, 1906.

WATER is sprayed into a current of air, and the air is then heated to vaporise the water. The mixed air and steam are passed through incandescent coke mixed with limestone, whereby a mixture of carbon monoxide and hydrogen, free from sulphur, is formed. The proportion of air to steam is so regulated that the temperature of the gaseous mixture produced is about 1100° C., and this mixture is caused to act upon the ore to be reduced in presence of a small percentage of carbon.—A. S.

Manganese steel; Process of treating [toughening] ——. W. Brinton, High Bridge, N.J., Assignor to Taylor Iron and Steel Co., New Jersey. U.S. Pat. 812,811, Feb. 20, 1906.



THE invention relates to a method of toughening manganese-steel. The steel is cast into its finished shape, allowed to solidify to a point at which it can be handled, and then covered with sand to check the cooling and to retain within the casting a part of its original heat, corresponding to a temperature of from 150° to 1000° F., according to the size, character and design of the article. At this point the steel is placed in a furnace previously heated to a temperature substantially corresponding to that of the article, heated rapidly to a predetermined temperature above a forging temperature, and then quickly cooled by immersing it in water.—A. S.

Metals [Iron and steel]; Process of treating ——. H. H. Goodsell, Indiana Harbor, Ind. U.S. Pat. 813,206, Feb. 20, 1906.

PLATES of sheet iron and steel are passed through a volatile liquid, dried by aid of heat, and then subjected to the action of a body of vapour heated unequally in different portions thereof, the plates being first exposed to portions of vapour at a relatively low temperature (400° F.) and then to portions of successively higher temperature (up to 900°—1200° F.). The plates are finally allowed to gradually cool in the open air.—A. S.

Smelting and converting ores; Process and apparatus for ——. A. M. Day, Butte, Mont. U.S. Pats. 812,186 and 812,785, Feb. 13, 1906.

THE apparatus consists of a smelting vessel, *a*, provided with a wind-box, *c*, and tuyères, *k*, and mounted on trunnions. One of the trunnions, *e*, is hollow, and communicates through the passage, *l*, with the wind-box, *c*. This trunnion has a detachable extension, *m*, which turns in the sleeve, *n*, on the main air-supply or blast-pipe, *o*. There is also a number of closed receptacles, *t*, for holding "fluent material" (fuel, fluxes, silicious materials), each of which is connected at the top with a source of compressed air, and has at the bottom a valve-controlled connection, *w*, with an auxiliary blast-pipe, *v*. The auxiliary blast-pipes are connected with flexible pipes, *s*, joined inside the trunnion extension, to pipes, *r*, leading to some of the tuyères. The process consists in covering the charge of ore with a molten substance containing sufficient heat to start the fusion of the charge, supplying air under

pressure from the main blast-pipe, *o*, through some of the tuyères to the top of the ore-charge, and injecting with separate and distinct air-blasts, fuel, fluxes and silicious materials from closed reservoirs, *t*. The tuyères are formed with fusible extensions, *x*, so that the blasts of air, &c., are still injected near the "melting-level" as the fusion of the ore-charge proceeds downwards.—A. S.

Ores; Process of treating ——. E. W. Arnold, Assignor to V. Selna, San Francisco, Cal. U.S. Pat. 812,473, Feb. 13, 1906.

THE process consists in "heating a body of ore to incandescence by directing into and against the ore a blast of a suitable hydrocarbon, and impregnating the incandescent ore with a mixture of chlorine gas and charcoal-fumes, in the proportion of about 2 parts of chlorine to 1 part of charcoal-fumes."—A. S.

Precious metals; Apparatus for treating slimes, &c., for the recovery of ——. C. Gluyas, Johannesburg, Transvaal. U.S. Pat. 812,418, Feb. 13, 1906.

THE apparatus consists of a series of elevating-wheels, each wheel being provided with a number of sets of elevating buckets, into which the material is fed in succession. Interposed between the different elevating-wheels are aërating devices consisting of a number of "superposed helically-disposed launders."—A. S.

Aluminium; Method of granulating ——. W. Hoskins, Lagrange, Ill. U.S. Pat. 812,493, Feb. 13, 1906.

ALUMINIUM and other metals, the oxides of which have a high melting point, are granulated by forcing an oxidising gas into the molten metal whilst subjecting the latter to mechanical stirring or agitation. As the mass cools, it solidifies in the form of superficially oxidised particles. —A. S.

Titanium; Process of combining —— with other metals. F. E. Canda, New York, Assignor to Chrome Steel Works, Chrome, N.J. U.S. Pat. 813,278, Feb. 20, 1906.

TITANIUM-BEARING material, and the material which is to be combined with titanium, are melted separately, and the molten substances poured simultaneously into a suitable receptacle. For example, titanium is combined with iron or steel by melting ferro-titaninm by the action of an electric current and adding it to the iron or steel which has been melted separately.—A. S.

Soldering compound. A. R. Hussey, Chicago, Ill. U.S. Pat. 812,494, Feb. 13, 1906.

SOFT soldering metal, composed, for example, of 1 part of tin and 3 parts of lead, is granulated, mixed with beeswax impregnated with zinc chloride, formed into bars or sticks, and coated with a skin of metal, *e.g.*, tinfoil, fusible at a moderate temperature. The beeswax may be hardened by admixture with resin.—A. S.

Coal; Apparatus for making artificial —— [*from slag*]. C. L. Mansfeldt, Munhall, and D. Cubbage, Swissvale, Pa. U.S. Pat. 812,650, Feb. 16, 1906.

See Eng. Pat. 22,932 of 1905; preceding these.—T. F. B.

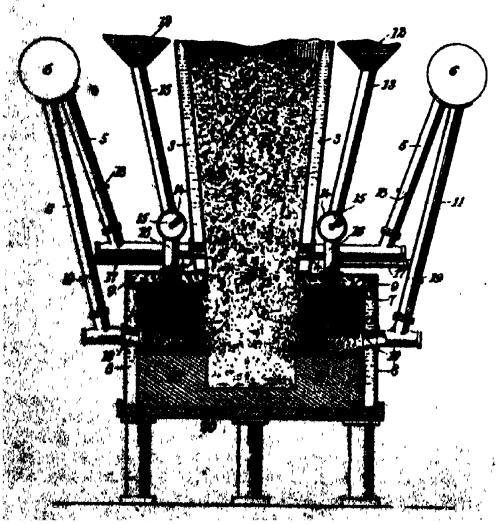
FRENCH PATENTS.

Coal; Manufacture of —— *and fusion or reduction of iron or other materials or metals.* E. T. Zohrab. Fr. Pat. 358,710, Oct. 21, 1905. Under Int. Conv., Oct. 21, 1904.

See Eng. Pat. 22,688 of 1904; this J., 1905, 1019.—T. F. B.

Phosphatic manure [*from slag*]; *Assimilable* ——. F. Laur. Fr. Pat. 350,443, Dec. 31, 1904. XV., page 275.

Ores with calcareous gangue; Process of concentrating low-grade ——. J. de Coppet. Fr. Pat. 358,089, Oct. 6, 1905.



THE ore is first roasted and then exposed to the atmosphere, whereby the lime formed on roasting falls to a fine powder, which can be separated more or less completely by sifting.—A. S.

Cooling and drying of large volumes of moist air [*for blast-furnaces*]; *Continuous process for* ——. Masch. Anst. Humboldt. Fr. Pat. 358,512, Oct. 14, 1905.

THE moist air is first passed, under considerable pressure, through a cooling chamber, the cooling coils of which have becomed covered with ice, and through which the cooling medium is not circulating. The ice is melted and the air is partially cooled, and is then passed at a lower pressure through other cooling chambers through the coils of which the cooling agent is circulating. The remaining moisture is desposited on the coils as ice, and the cooled, dried air passes away. By a system of valves and dampers the direction of the air through the series of coolers can be varied, so that, while some are working actively as coolers, others are having the ice melted by the incoming air. Further claim is made for utilising the heat of the waste gases from a blast-furnace or from gas-engines to liberate the ammonia used as the refrigerating medium from the water by which it has been absorbed after it has effected the cooling.—W. H. C.

Furnace; Blast ——. W. Kemp. Fr. Pat. 358,645, Oct. 18, 1905. Under Int. Conv., June 30, 1905.

THE furnace is shown in cross-section in the accompanying diagram. It consists of an ore-chamber surrounded by a water-jacket, 3, and disposed above a fuel-chamber, 7, which is also surrounded by a water-jacket, 8, 9, and extends the whole length of the furnace. Two sets of

tuyères, 4, and 10, respectively, are provided, connected separately to the blast-pipes, 5, by the pipes, 6, and 11, having dampers, 18, and 16. The hearth, 20, has, on either side, walls, 21, of refractory material. In starting the furnace some wood is set on fire in the fuel-chamber, the blast is started, and coal is gradually introduced from the hoppers, 12, through the pipes, 13, and 14, the latter being provided with screw-conveyors, 15, which feed the coal through the pipes, 16, into the fuel-chamber. The pipes, 16, are connected to pipes, 11, by tubes, 17, so that a downward current of air passes through 16, and prevents the coal becoming ignited before it reaches the fuel-chamber. When the coal in the fuel-chamber is heated to incandescence, ore is fed in at the top of the furnace, and gradually forms a heap in the middle of the fuel-chamber, so that when the furnace is in operation, the ore is reduced without becoming admixed with the fuel. When the ore to be reduced, contains sulphur, the dampers, 18, are opened to a suitable extent, and the sulphur is burnt by the blast entering the furnace through tuyères, 4, before the ore reaches the fuel-chamber.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 223.)

(A.)—ELECTRO-CHEMISTRY.

Nitrogen combustion; Theory of ——. P. A. Guyé. Chem. Ind., 1906, **29**, 85—88.

WHEN nitrogen and oxygen unite at the temperature of the electric arc, nitric oxide is the product, which, when its temperature falls below 500°—600° C., unites with more oxygen to form nitrogen peroxide. From this are formed by well known and purely chemical reactions nitric acid or nitrates. The reaction $N_2+O_2 \rightleftarrows 2NO$ is reversible, and the higher the temperature the more rapidly is equilibrium attained in the direction of formation of NO; so that the most favourable conditions for yield of product are found in extremely high momentary arc-temperatures followed by extremely rapid cooling. These conditions are reached in practice by passing a stream of air through the arc or by causing the arc continually to change its position. The most favourable results yet attained give a yield of 800—900 kilos. of nitric acid per kilowatt-year at the arc, which probably means, allowing for dissociation during cooling, 500 kilos. per kilowatt-year of actual yield. Under favourable conditions for electric generation, this would work out to about 12 frs. per 100 kilos. of nitric acid; and, as the present price of that amount is, as acid, 45 frs., and as nitre, 35 frs., there is a reasonable prospect of nitric acid being profitably produced by the new process. The author points out that in manufacturing crude calcium cyanamide, the necessary nitrogen is often obtained from liquid air, the oxygen of which is then a waste product. If this oxygen were applied to enrich the air subjected to the influence of the electric arc, the yield of nitric oxide would be increased; thus the manufacture of calcium cyanamide and that of nitric acid might be carried on concurrently more economically than either separately.—J. T. D.

Hydrogen peroxide and other compounds; Note on the formation of —— *by means of the Tesla-discharge.* A. Findlay. Z. Elektrochem., 1906, **12**, 129.

As Nernst has stated (Z. Elektrochem., 1905, **11**, 710) that hydrogen peroxide could not be detected when an electric spark is passed through a mixture of oxygen and water vapour, the author records some preliminary experiments in which hydrogen peroxide was formed by a Tesla brush-discharge through water vapour. Oxides of nitrogen are produced from nitrogen and oxygen, ammonia from nitrogen and hydrogen, and hydrazine from ammonia and nitrogen under similar conditions.—J. T. D.

Thiosulphates; Electrolytic formation of ——. Levi and Voghera. Atti. R. Accad. dei Lincei Roma, 1905 (Ser. 5), **14**, 433; Z. Elektrochem., 1906, **12**, 131.

It is shown that upon electrolysis of mixed solutions of sulphides and sulphites, thiosulphates are produced. This is ascribed to reaction at the anode between the ions as they are discharged.

$$SO_3'' + S'' + 2\oplus = S_2O_3''.$$

The best results are obtained in a cell without diaphragm, and when the electrolysis is carried out at 25° C. The variation of the current density between 16·6 and 33·3 ampères per sq. dm. does not appear to influence the yield. A current efficiency of from 9 to 16·6 per cent. was obtained in the different experiments.—R. S. H.

Metals, especially gold and palladium; Determination of —— by electric conductivity measurements. J. Donau. XXIII., page 285.

Bismuth; Peroxides of ——. *II. Oxidation of bismuth oxide by electrolytic chlorine in presence of potassium hydroxide, and the so-called "potassium bismuthate."* A. Gutbier and R. Bünz. VII., page 264.

Chlorine; Action of silent electric discharge on ——. F. Russ. VII., page 264.

Electrolysis of water; Apparatus for the ——. K. J. Vareille, Levallois-Perret, France. Eng. Pat. 20,217, Oct. 6, 1905.

SEE Fr. Pat. 355,652 of 1905; this J., 1905, 1240.—T.F.B.

UNITED STATES PATENTS.

Furnace; Electric ——. J. E. Ober, Schenectady, N.Y., Assignor to General Electric Co., N.Y. U.S. Pat. 812,801, Feb. 13, 1906.

THE furnace comprises a carbon tube, with two cylindrical end portions, and an intermediate portion of less diameter, heated by the passage of the current through its wall. A sheath is formed by wrapping paper around the end portions, and the space between the intermediate portion of the tube and the paper is filled with a sintered mass of finely-divided titanium carbide, which is non-hygroscopic and refractory. A packing of heat-resisting material, such as coke, surrounds the carbide and the end portions of the tube.—B. N.

Flour; Method of [electrically] treating ——. J. E. Mitchell, Assignor to Alsop Process Co. U.S. Pat. 812,764, Feb. 13, 1906. XVIII*A*., page 278.

Bleaching liquors; Apparatus for [electrolytically] preparing ——. F. L. Bartelt, Bristol. U.S. Pat. 813,688, Feb. 27, 1906.

SEE Eng. Pat. 16,185 of 1904; this J., 1905, 678.—T. F. B.

FRENCH PATENTS.

Filament; [Electric furnace for making] an indestructible —— for lighting and heating. G. Michaud and E. Delasson. Second Addition, dated Sept. 30, 1905, to Fr. Pat. 346,307, Sept. 17, 1904 (this J., 1905, 125, 612 and 1057).

THIS addition relates to an electric furnace for fusing the materials employed in making the filaments. The furnace consists of a base or block in which is sunk a carbon crucible, in which the materials are fused. One electrode passes up into the crucible through the bottom, and the other is arranged to hang down into the crucible. The materials are supplied from a feeding hopper, and the fused material is drawn out in the form of a filament by means of a rod. The success of the operation requires that the fluidity of each composition is determined and the rate of drawing adapted to it. The materials specified are alumina, lime, silica or magnesia, rendered conductors by an addition of carbon, vanadium, osmium or tantalum, and the quality of the radiation is determined by an addition of an oxide, such as chromium oxide.—W.C.H.

Chlorates and perchlorates; Electrolytic manufacture of alkali ——. M. Couleru. Fr. Pat. 358,798, Oct. 24, 1905.

SEE U.S. Pat. 788,631 of 1905; this J., 1905, 620.—T.F.B.

GERMAN PATENTS.

Electrodes of alkaline accumulators; Employment of cellulose derivatives for the separation of the ——. Kölner Akkumulatorenwerke Gottfried Hagen. Ger. Pat. 165,233, Aug. 3, 1904.

THE electrodes of alkaline accumulators are separated by an intermediate layer or layers of artificial silk, prepared by precipitating a cuprammonium solution of cellulose with sulphuric acid.—A. S.

Carnallite and other haloid double salts of the alkaline-earths; Apparatus for the continuous treatment of fused —— by electrolysis. E. Haag and F. Glinicke. Ger. Pat. 163,413, Jan. 20, 1904.

THE invention relates to improvements in apparatus for the electrolysis of fused carnallite and other haloid double salts of the alkaline-earths, in which provision is made for the separate discharge of the liberated metals and the gaseous decomposition products. The chamber in which the molten decomposition products collect is provided with an overflow tube for the escape of the light metal, and also, at the bottom, with grooves or passages through which the residue passes into a receptacle, from which it is continuously discharged by means of a siphon-tube. —A. S.

Sodium chromate; Electrolytic manufacture of —— from chrome iron ore. Chem. Fabr. in Billwärder vorm. Hell und Sthamer A.-G. Ger. Pat. 163,541, Feb. 28, 1904.

A FUSED mixture of chrome iron ore and caustic soda is electrolysed and air is simultaneously introduced, whereby it is stated sodium peroxide is formed and acts as an oxygen-carrier.—A. S.

Ammonia-soda manufacture; Process for the [electrolytic] treatment of the waste solutions of —— with recovery of brine for use over again. A. Riedel. Ger. Pat. 164,726, March 8, 1904.

THE waste solutions are mixed with strong brine, and electrolysed for the decomposition of the calcium chloride into calcium hydroxide and chlorine. The residual salt solution is used again in the process for dissolving further quantities of salt.—A. S.

(*B.*)—ELECTRO-METALLURGY.

Strontium; Preparation and properties of ——. Guntz and Rœderer. Comptes rend., 1906, **142**, 400—401.

THE authors have prepared strontium by a method exactly analagous to that for barium (this J., 1906, 80), as a silver white metal, readily tarnishing in air, melting at 800° C. It readily decomposes water or alcohol in the cold. Its heat of oxidation is intermediate between those of barium and calcium.—J. T. D.

ENGLISH PATENT.

Smelting of ores, iron sand and the like; [Electric] Method of and apparatus for ——. T. S. Anderson, Sheffield. Eng. Pat. 6001, March 22, 1905.

VERTICALLY adjustable and water-jacketed electrodes are provided within the furnace and electro-magnets below the floor of the furnace. The current passes in succession through the electrodes, the air-space between the electrode and the slag-line, the slag, and the molten metal; and returns through a wire which has its terminal at the base of the furnace. The current is regulated by varying the breadth of the air-space. The ore is made to fall between the electrodes, where it is melted; it then falls into a receiver from which it may be withdrawn through a tapping hole.—J. H. C.

UNITED STATES PATENT.

Metals of the earthy alkalies: Process for the electrolytic production of ——. C. Suter and B. Redlich, Ratibor, Germany. U.S. Pat. 813,532, Feb. 27, 1906.

SEE Eng. Pat. 26,655 of 1903; this J., 1903, 1299.—T.F.B.

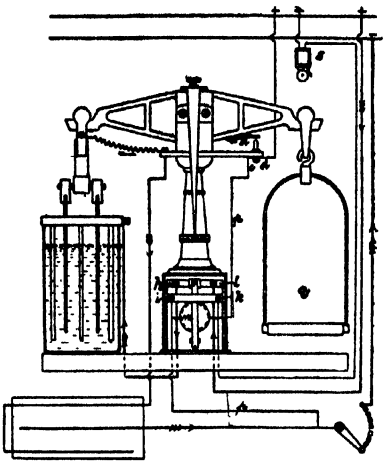
FRENCH PATENTS.

Nickel or its alloys; Manufacture of —— [*electrically*]. G. H. Gin. First Addition, dated Sept. 26, 1905, to Fr. Pat. 344,202, June 22, 1904 (this J., 1904, 1098).

THE process described in the main patent is extended to the production of other metals or alloys free from carbon, such as chromium, manganese, tungsten, molybdenum, ferro-chromium, ferro-tungsten, &c. The outer vessel of the electric furnace is formed from a basic silicate of the metal to be obtained, and the electrodes of a silicide of the same metal. The final slag may be used for the regeneration of the reducing silicide.—B. N.

Carborundum or boron carbide; Manufacture of formed or moulded articles of ——. F. Bölling. First Addition, dated Sept. 30, 1905, to Fr. Pat. 353,017, Mar. 29, 1905 (this J., 1905, 976).

INSTEAD of heating articles of pure carbon in a bed of carborundum or of boron carbide, as described in the principal patent, the carbon articles are now heated in cavities made in pieces of carborundum or of boron carbide. In this way the silicon or boron penetrates the carbon more thoroughly, and the surface is less altered, any factory marks, &c., on the latter not being effaced.—A. G. L.



Carborundum or boron carbide; Manufacture of formed or moulded articles of ——. F. Bölling. Second Addition, dated Sept. 30, 1905, to Fr. Pat. 353,017, March 29, 1905 (this J., 1905, 976).

THE modification consists in heating the articles made of pure carbon in a bed consisting of a mixture of sand and carbon, or of boric acid and carbon, instead of in a bed of carborundum or boron carbide, as described in the principal patent.—A. G. L.

GERMAN PATENT.

Voltametric balance for obtaining a definite weight of deposit in electrolytic baths, an electro-magnet being used as current interruptor. H. Helbig. Ger. Pat. 162,591, March 17, 1904.

THE apparatus is shown in the accompanying figure, the normal path of the current being indicated by the arrows. When weights are placed in the scale-pan, *q*, the projecting piece, *a*, on one arm of the balance is brought down on to the contact piece, *c d*, forming a circuit, *p*, in which the electro-magnet, *m*, is included. As soon as the weight of the electrolytic deposit is sufficient to bring the balance back to the normal position, the circuit, *p*, of the electro-magnet is opened, and by release of the armature of the magnet, the main circuit is broken by rupture of the contact between *k* and *l*, whilst

simultaneously by means of the contacts, *i*, *h*, a circuit including the bell, *s*, is formed.—A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 224.)

Cod-liver oil and other fish oils; Examination of ——. II. R. T. Thomson and H. Dunlop. Paper read before Scottish Section Soc. Chem. Ind., Jan. 16, 1906. 1—8.

IN a former paper (this J., 1905, 741) the authors showed that the refractive index had no independent value as a test of the purity of cod-liver oil, and they now describe experiments to show that it throws no additional light on the effect of oxidation. A sample of cod-liver oil that had been kept for three years in a bottle, from which the air was not entirely excluded, gave the following results:—Iodine value (Wijs) 156·5; butyro-refractometer reading at 25° C., 80·3; saponification value, 191·4; specific gravity at 15° C., 0·9368; free acid, as oleic acid, 1·24 per cent.; Reichert-Wollny value, 2·0. If the Reichert and saponification values of this oil were alone taken into account, the presence of a small amount of an oil such as porpoise oil would be indicated, but the iodine value and specific gravity show that oxidation has taken place. In the authors' experience the Reichert-Wollny value for fresh cod-liver oil is less than 1, but in a partially oxidised oil it may exceed 3. In the colour test with sulphuric acid, this partially oxidised oil gave only a brown coloration, and not the characteristic reaction. A sample of fresh seal oil gave the following results:—Iodine value (Wijs) 162·6; butyro-refractometer reading at 25° C., 76·2; saponification value, 190·0; unsaponifiable matter, 0·24 per cent.; sp. gr. at 15° C., 0·9267; free acid, as oleic acid, 0·29 per cent.; specific rotatory power, - 0·19; Reichert-Wollny value, 0·6; molecular equivalent of fatty acids, 284·0. This oil of undoubted purity, gave a distinct violet coloration with sulphuric acid, both before and after stirring, whilst the fatty acids also gave a similar though more fugitive coloration. The same reaction was also given by this oil after being kept for two months in a closed bottle. Fish oils generally become darker on saponification, but this was not the case with the seal oil. The authors' general conclusion is that seal oil might be added in large proportion to cod-liver oil without risk of detection by analytical methods.—C. A. M.

Oils; Behaviour of vegetable —— with regard to polarised light. M. A. Rakusin. Chem.-Zeit., 1906, 30, 143—144.

THE author asserts that Walden's work on this subject has been forgotten. (See, however, Lewkowitsch, "Oils, Fats and Waxes," p. 210.) He has examined 24 vegetable

oils in a Soleil-Ventzke apparatus and has observed marked rotation in the following cases:—Castor oil, +8 to +8·65°; croton oil, +14·5° to +16·4°; sesamé oil, 1·9° to 2·4°; and laurel oil, +14·4°. The values of the first three oils agree well with those obtained by Walden, and in the author's opinion +8° may be regarded as a constant for castor-oil. The rotations were determined in a 200 mm. tube, whilst that of the semi-solid laurel oil was determined in an ether solution in a 50 mm. tube. It was found that the rotation of this oil was not due to chlorophyll, for an ethereal solution of chlorophyll was opaque to polarised light, even in a dilution of 1:3200. The following results were obtained with the other oils, a 200 mm. tube being used except where otherwise stated:—Olive oil, +0·2°; arachis oil, —0·4°; almond oil, —0·1°; rape oil, —0·1° to —0·2°; back mustard seed oil, —0·1° (in 100 mm. tube); cottonseed oil, —0·1°; hemp seed oil +0·1° (in 100 mm. tube); linseed oil, +0·2° (in 100 mm. tube); cameline oil, —0·1°; poppy oil, +0·1°; walnut oil, +0·15; sunflower oil, +0·1°; cacao butter (50 per cent. solution in benzene) +0·1° (×2); cocoa-nut oil (50 per cent. solution in benzene), +0·19° (×2); palm oil, +0·1° (×2); reseda oil +0·6°; and jasmine oil +0·9°. The high values of the two last oils were attributed to the presence of essential oils.—C. A. M.

Cottonseed Oil and Oil Cake trade of Marseilles. For. Off. Ann. Ser., No. 3534.

COTTONSEED oil imports at Marseilles during 1905 reached a net total of 32,448,588 kilos.; of these 32,282,968 kilos. came from America, 80,253 kilos. from the United Kingdom, and 85,367 kilos. from other countries. During 1904 less than half this amount was imported—15,003,403 kilos.—whereof 13,384,415 kilos. came from America, 1,323,846 kilos. from the United Kingdom, and 295,142 kilos. from other sources. Imports from America show an increase from an average of 13,500,000 kilos. for the three preceding years to 32,282,968 kilos., whereas imports from the United Kingdom fell from an average of 1,250,000 to 80,253 kilos.

During 1905, 179,700 tons of oil-cake were produced at Marseilles. Of this amount 58,000 tons were made from shelled earthnuts from Bombay, Coromandel and Mozambique, 42,000 tons from copra, 24,000 tons from the residue of gingelly seed imported from India and Africa, 20,000 tons from unshelled earthnuts. Other kinds of oil cake included those manufactured from the residues of white gingelly from the Levant, 1,800 tons; linseed, 7,200 tons; rape seed and colza, 200 tons; Egyptian cotton seed, 11,000 tons; poppy seed from India and the Levant, 2,200 tons; castor oil from India and the Levant, 9,600 tons; palm kernels, 1,400 tons; mowra and others, 2,300 tons.

Marseilles imported from foreign countries 29,800 tons of oil cake made from Russian colza and 3000 tons of other kinds, a total of 32,800 tons against 33,000 tons for 1904. Northern France, Germany and Scandinavia are the best buyers of the Marseilles earthnut cake. The South of France consumes a considerable quantity of oil-cake for manure, used in raising early vegetables.

[T.R.]

Oleic Acid. U.S. Customs Decision, Jan. 18, 1906.

THE United States Circuit Court affirmed a decision of the Board of General Appraisers, which held oleic acid or red oil to be dutiable at 25 per cent. *ad valorem* under paragraph 1 of the tariff as an "acid not specially provided for." In view of the fact that the evidence showed other uses for the article than soap making, the claim of the importer for free entry as an "oil commonly used in soap making and fit only for such use" under paragraph 568 was overruled. [T.R.] R. W. M.

ENGLISH PATENTS.

Fats, fat oils, resins and the like; Purification of ——. C. Fresenius, Offenbach a/Main, Germany. Eng. Pat. 10,387, May 17, 1905.

SEE Fr. Pat. 354,810 of 1905; this J., 1905, 1117.—T. F. B.

[*Castor*] *Ricinus oil product; Manufacture of* ——. Oelwerke Stern-Sonneborn, Akt.-ges., Hamburg, Germany. Eng. Pat. 24,935, Dec. 1, 1905. Under Int. Conv., Dec. 9, 1904.

CASTOR oil is heated in an autoclave or closed boiler under pressure until it will mix with mineral oil in any proportion. The most suitable temperature is 260° to 300° C., with a pressure of 4 to 6 atmos., the time required being about 10 hours. It is stated that there is no risk of forming a gum-like product as in methods where the oil is distilled.—C. A. M.

[*Castor*] *Ricinus oil product; Manufacture of* ——. Oelwerke Stern-Sonneborn, Akt.-ges., Hamburg, Germany. Eng. Pat. 24,936, Dec. 1, 1905. Under Int. Conv., Dec. 9, 1904.

CLAIM is made for a modification of the method described in the preceding patent. It consists in heating the oil beneath a reflux condenser, suitable conditions being a temperature of 260° to 300° C. and a pressure of 4 to 6 atmos.—C. A. M.

UNITED STATES PATENT.

Lead compounds; Dry method of preparing ——. J. P. Neville, Oakland, Cal. U.S. Pat. 812,357, Feb. 13, 1906.

THIS invention relates to a dry method of preparing white lead, red lead, and litharge for commercial use, and consists in subjecting the material to the action of a pulveriser so as to reduce it to a powder, the latter being then withdrawn from the pulveriser by air suction. The flowing body of air is impregnated with a gas, such as ozone, "to oxidise and eliminate all foreign substances and such acetate of lead as may be contained in the powdered carbonate carried by the body of air." The dust-laden air is discharged into an "arrester," wherein the heavier particles of lead carbonate are deposited, and the air is finally discharged into a "collector" to finally free it from any particles of carbonate still suspended in it.—B. N.

FRENCH PATENT.

Lakes [from azo dyestuffs] suitable as substitutes for Chrome Yellow; Process for preparing yellow ——. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 350,431, Dec. 28, 1904.

(*B.*)—RESINS, VARNISHES.

Gutta-percha Resin. U.S. Customs Decision, Jan. 11, 1906.

RESIN extracted from gutta-percha for the purpose of purifying the latter, is dutiable under section 6 of the tariff at 20 per cent. *ad valorem* as a "manufactured article unenumerated." The claims of the importer for free entry as "crude resin," and at 10 per cent. *ad valorem* as an "unmanufactured article unenumerated" were overruled. [T.R.] R. W. M.

UNITED STATES PATENT.

Turpentine; Process of refining ——. G. O. Gilmer, Assignor to American Turpentine and Tar Co., Ltd., New Orleans, La. U.S. Pat. 813,088, Feb. 20, 1906.

THE crude turpentine, obtained by the distillation of turpentine-bearing wood, is allowed to settle and the pyroligneous acid and other liquids of greater specific gravity than turpentine are drawn off. The separated turpentine is then mixed with about 50 per cent. of pure water and the mixture is distilled at such a temperature, above that of boiling water, that both are vaporised together. The vapours are condensed and separated, and the turpentine is treated with sufficient lime-water or other liquid alkali to neutralise the acids present, and air is blown through the liquid to aërate and agitate it. After settling, the turpentine is again separated and distilled with water at a temperature of approximately 335° F., the vapours are condensed and the turpentine is finally separated by settling and decantation from the water that has distilled over with it.—W. H. C.

(*C.*)—INDIA-RUBBER, ETC.

Latex; New East African —— and the product of its coagulation. E. Marckwald. Gummi-Zeit., 1906, **20**, 491—492.

THE latex, the botanical source of which is not given, had a sp. gr. of 1·0429 and the following composition:—Water lost at 100° C., 58·55; mechanical organic impurities, 2·30; mineral constituents, 0·35; resins, 32·75; rubber-like substance, 5·40; and albuminoid matter, 0·65 per cent. A sample of the product of coagulation sent to the author had an appearance somewhat similar to that of raw balata, which it also resembled in properties. The following was its composition:—Water lost at 100° C., 12·78; mechanical organic impurities, 3·82; mineral constituents, 10·94; resins, 60·17; and rubber-like substance (containing small quantities of albuminoids), 12·29 per cent. The rubber-like substance behaved normally towards solvents and precipitants, resembling rubber and not gutta-percha in not being precipitated from solution by ether.

The resins were separable into two substances, melting at about 80° C., and about 130° C. respectively. The mineral constituents included about 10 per cent. of alum used in the coagulation process. The coagulation product as prepared by the author (*a*) by dilution of the latex, and boiling, (*b*) by the addition of 5 per cent. acetic acid to the latex, had the following compositions respectively, after washing and drying:—

	Product (*a*).	Product (*b*).
	Per cent.	Per cent.
Mineral constituents	0·83	0·80
Albuminoid matter	1·57	1·58
Resins	78·29	79·43
Rubber-like substance	19·81	18·24

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 225.)

Extractor for tanning materials. H. C. Reed. Collegium. 1906 [193], 49.

Fig.1.

THE method of using the apparatus is as follows, the parts being assembled as shown by the drawing:—

The bark or other material is introduced into the cup, B, and rests upon the wire mesh screen, 26, and prevented by it from passing to the bottom of the cup. If it is desired to extract the same at a temperature less than that of boiling water, water at the desired temperature is introduced into the vessel, A, through the funnel, 13, and pipes, 11 and 9, or cold water may be thus introduced to the vessel and the temperature thereafter raised by a heater placed under the bottom of the vessel, A. The water is then run into the vessel until it overflows through the faucet, 20, thus surrounding the cup, B, with water at any desired temperature not exceeding 212° F. Water can be introduced into the cup, B, by pouring it into the same or by closing the overflow faucet, 20, and allowing the water to rise in the vessel until it shall overflow the edge of the cup, B, or by means of an inverted vessel filled with water, the open mouth of which dips below the level of the water in cup, B, and which automatically replenishes the water in cup, B, at a rate equivalent to the lowering of the level of the water therein. The water percolates through the material in the cup carrying the soluble matters therefrom through the screen to the bottom. When the water in the cup rises above the top of the siphon, the solution in the bottom of the cup will flow through the siphon and may be drawn off through the faucet, 17. The rapidity of percolation and outward flow through the siphon, is controlled at the faucet, 17.

If it be now desired to extract by means of condensed steam, the faucet, 10, is opened and the water in the vessel is drawn down to the desired level indicated by the gauge glass, 12. The faucet, 10, is then closed and the condenser attached to the top of the vessel, A. Heat is applied to the bottom of the vessel, A, and the steam from the water therein passes through the partition, 22,

and around the cup, B, into the condenser, whence the condensed water drops back into the cup, B, upon the contained material. The cup, B, is thus gradually filled by the water until the siphon is covered, when the liquor is siphoned out of the bottom of the cup in the manner described. If continuous extraction be desired, the faucet, 17, is kept closed and the cock, 16, opened to the desired extent, thus maintaining circulation through the apparatus.

It has been found advantageous to vary the size of the cup with the bulk of the material to be extracted, and for this reason cups of the style shown in Fig. 2 were designed. When small amounts of material are extracted, a greater mechanical action results from the use of a cup of a size only sufficiently large to comfortably contain it, and better extraction results.

Tanning materials; Action of formaldehyde on ——. [*Differentiation of pyrogallol and protocatechuic groups.*] E. Stiasny. Pharm. Centralh., 1906, **47**, 27.

By boiling 50 c.c. of the clear decoction of a tanning material, of the usual strength, for ten minutes under a reflux condenser, with 10 c.c. of hydrochloric acid solution (1·1), and 10 c.c. of formaldehyde solution (40 per cent.), protocatechuic tanning substances can be distinguished from those of the pyrogallol group. The former, including quebracho, catechu, mallet-bark, mangrove, hemlock, pine, fir, Aleppo pine, mimosa, birch, willow, palmetto, cajotta, oak bark, canaigre, kermek, *Pistacia lentiscus*, sumach, and gambier are entirely precipitated. Pyrogallol materials, such as oakwood, chestnut, galls, valonia, myrabolans either give no precipitate, or but a slight one. By allowing the reaction to proceed at normal temperatures for everal days, materials of the protocatechuic group may be separated into two classes, one of which is entirely, the other only partially, precipitated. The latter includes oak, fir, and birch barks, palmetto, sumach, and some kinds of quebracho extract. This reaction enables the adulteration of tanning materials of the protocatechuic group with those of the pyrogallol group to be detected; for instance, the presence of oakwood or chestnut wood extract in quebracho extract, but the method cannot be employed quantitatively. Tannin-containing fruits, such as divi-divi, algarobilla, teri, and bablah, give a copious precipitate due to the presence of gallic acid. Algarobilla, after the removal of the gallic acid, gives no precipitate, whereas divi-divi gives a copious one, probably of ellagic acid. Sumach, on account of its large percentage of gallic acid, falls into the protocatechuic group. After removing this, its pyrogallol characters become evident.—J. O. B.

Hydroxybenzoic acids; Some oxidation products of the ——. *II.* A. G. Perkin. IV., page 258.

Casein. U.S. Customs Decision.

The United States Circuit Court, January 18, 1906, held that certain *caseine industrielle* is free of duty as "lactarene" under paragraph 594 of the free list. The Board of General Appraisers had held the article to be dutiable at 20 per cent. *ad valorem* as a "manufactured article unenumerated" under section 6, but in view of additional testimony, showing that casein was commercially known as lactarene, the above decision was rendered. The Treasury Department, February 3, 1906, acquiesced in this decision, but on information received that the record in the case was incomplete, and that the commercial designation of casein can be shown not to be lactarene, the Department, February 12, 1906, ordered another case to be prepared for trial. (*Continued from page* 130.)

Nitrification: Influence of organic matter on ——. A. Müntz and E. Lainé. Comptes rend., 1906, **142**, 430—435.

The authors' experiments show that humus, in whatever abundance it may be present, is not prejudicial to nitrification, and, indeed, is rather favourable to it. Humus, however, is not necessary for nitrification can be produced in soils poor in organic matter. The humus seems to aid the multiplication of nitrifying organisms, and as a rule a soil contains more active organisms and is more prone to enter into nitrification as it contains more humus.

—J. T. D.

French Patent.

Phosphatic manure [from slag]; Assimilable ——. F. Laur. Fr. Pat. 350,443, Dec. 31, 1904.

Molten slag, as it flows from a metallurgical or other furnace, is received in a supplementary furnace or in a heated receptacle, in which it is mixed with powdered natural phosphates, such as coprolites, phosphorites, &c. It is stated that the tricalcium and dicalcium phosphates are decomposed by the silica in the slag, new and more fusible silicates being formed, whilst the phosphoric acid present is rendered soluble and assimilable by plants. The product obtained may be granulated and powdered.

XVI.—SUGAR, STARCH, GUM, Etc.

(*Continued from page* 227.)

Sugar cane experiments in the Leeward Islands. Report on experiments conducted at Antigua and St. Kitts in the season 1904-5. Part I. Experiments with varieties of sugar cane. The Imperial Department of Agriculture for the West Indies, 1905.

Experiments on the cultivation and selection of improved varieties of the sugar cane have been conducted at the experiment stations in Antigua and St. Kitts. The canes were cultivated throughout in the same manner as the ordinary crop of the estate so as to give results closely comparable with those obtained by the planter. The severe drought in Antigua, however, was such as to cause the sugar crop to drop from the normal 13,000 tons to 7,800 tons. The rainfall in St. Kitts, though heavier than in Antigua, was irregular and gave varying results on the different estates. In Antigua the following canes stand out as specially worthy of attention:—B. 156, Sealy Seedling, B. 306, B. 208, D. 74, D. 95 and D. 109, both as plant canes and ratoons. At St. Kitts the best results were obtained with Caledonian Queen or White Transparent; B. 208 and B. 147 were satisfactory, and D. 74 and D. 116 are recommended for cautious planting. B. 208, heads the list of canes grown as ratoons with a yield of 30 tons per acre, and 8·508 lb. of sugar in the juice (per Imperial gall.), and the opinion is expressed that this cane may be generally introduced at St. Kitts to occupy a useful position with the Caledonian Queen and B. 147. There was an almost complete absence of rotten canes, a result directly traceable to the introduction of new varieties of cane. In order to ascertain whether any of the 35 varieties under experimental cultivation exhibited any evidences of abnormal quotients of purity due to high polarisation, juice from each variety grown at Cassada Garden was examined by the Clerget method, using the factor 144. Six of these show what may be regarded as abnormally high apparent purities, namely Red Ribbon, Queensland Creole, D. 74, D. 89, D. 99 and D. 116. During the recent dry season, considerable trouble has been experienced from "gum" which appears to be worse when the normal development and ripening of canes are arrested.

In the following table the results are given of those varieties which gave most satisfactory results:—

No.	Name of cane.	Direct polarisation.	Polarisation due to sucrose — Clerget.	Apparent sucrose lbs. per gall.	True sucrose lbs. per gall.	Difference between true sucrose and apparent sucrose.	Apparent purity.	True purity.	Difference between true purity and apparent purity.

Indian cane jaggeries; Use of saturation in the refining of ——. B. Ryznar. Z. Zuckerind. in Böhmen, 1906, **30**, 233—258.

THE process of double carbonatation and saturation, followed by a sulphitation of the thick juice, as practised in the beet sugar industry, may be applied with advantage in the refining of Indian cane jaggeries. The experiments of the author, based on analyses of the scums and juices at each stage have led him to recommend the following treatment for this class of raw sugar:—The jaggery is melted to a juice of 20° B. It is then warmed or cooled to a temperature of 45°—50° C. and is treated without delay with a quantity of milk of lime, equal to 4·5 per cent. of calcium oxide on the weight of the raw jaggery. The juice is saturated with carbon dioxide until it possesses a residual alkalinity equal to 0·06 grm. of lime per 100 c.c.; it is then heated to 60° C. and filtered. For the second carbonatation, 1 per cent. of lime, calculated on the original jaggery, is added, the juice is rapidly saturated until neutral, heated to 70° C. and filtered; it is then boiled, filtered again, and concentrated to a density of 25°—30° B. If the acidity of the thick juice exceed 0·03 per cent., calculated as calcium oxide, lime is added to reduce it to that degree of acidity, and sulphur dioxide is then passed in until the acidity, expressed as calcium oxide, reaches 0·06 per cent. After that, the juice is boiled and refined in the usual way. According to the analyses, the above treatment effected the removal of 27·86 per cent. of the total non-sugar constituents of the jaggery (30·58 per cent. of the organic and 18·62 per cent. of the mineral impurities) and eliminated 74·74 per cent. of the colouring matter. The bulk of the purification is effected by the first saturation, but the other treatments cannot be omitted without loss of efficiency, since the precipitation of certain coloured impurities, *e.g.*, basic calcium glucinate, requires the close observance of certain conditions of alkalinity and temperature only obtainable by double saturation.—J. F. B.

Sugars; Action of secondary asymmetric hydrazines [*Ethylphenylhydrazine*] *on* ——. R. Ofner. Monatsh. Chem. 1906, **27**, 75—80.

NEUBERG (this J., 1902, 506) stated that methylphenylhydrazine only yields osazones with ketose sugars and not with aldoses, but the author (this J., 1905, 47) and Ost (this J., 1905, 935) have shown that such is not the case. The author has now studied the action of ethylphenylhydrazine on levulose and dextrose.

An osazone is prepared from levulose by treating a solution of 3·6 grms. of the sugar in 15 c.c. of water with 8·2 grms. of ethylphenylhydrazine, 8 c.c. of 50 per cent. acetic acid, and 2 c.c. of alchool. An oil is formed after a few minutes which crystallises after a few hours. The osazone crystallises from 50 per cent. alcohol as fine yellow needles melting at 143° C., yield 60 per cent. The same osazone is formed from dextrose by treating 1·8 grms. of the sugar dissolved in 12 c.c. of water with 4·2 grms. of the hydrazine, 4 c.c. of glacial acetic acid and 3 c.c. of alcohol at the ordinary temperature, for about 20 hours; yield 55—60 per cent. If the mixture be heated, the osazone can be separated in the crystalline form after only two to three hours.

Dextrose ethylphenylhydrazone is prepared by heating 5·4 grms. of dextrose with 30 c.c. of 90 per cent. alcohol and 4·3 grms. of the hydrazine. After evaporation *in vacuo* at the ordinary temperature, the syrup begins to crystallise in about two days. The crystals retain alcohol of crystallisation and soften at 80° C., but if the alcohol be removed, the substance melts fairly sharply at 116°—118° C.; yield 60—70 per cent.—J. F. B.

Worts and sugar solutions; Determination of extract in ——. H. van Laer. XXIII., page 286.

Sugar bounties and excise tariff; Australian ——. Bd. of Trade J., March 8, 1906.

AN Act of the Australian Commonwealth, entitled the "Sugar Bounty Act, 1905" (No. 23 of 1905), was assented to on the 21st December, 1905. This Act provides that after 1st January, 1907, there shall be paid out of the Consolidated Revenue Fund to every grower of white-grown cane or beet within the Commonwealth, a bounty on all such cane or beet delivered for manufacture after that date and before the 1st January, 1913, at the following rates:—

Sugar cane.—6s. per ton calculated on cane giving 10 per cent. of sugar, to be increased or decreased proportionately according to any variation from this standard.

Beet.—60s. per ton on the actual sugar-yielding contents of the beet.

It is further provided, however, that the rates payable on all such cane or beet delivered during the years 1911 and 1912 shall be respectively two-thirds and one-third of the aforesaid rates.

The "Excise Tariff, 1905" (No. 24 of 1905), which was assented to by the Federal Parliament on the same day, *viz.*, 21st December, 1905, as the Sugar Bounty Act of 1905, provides that the excise duty imposed on sugar by the excise tarift of 1902 shall be increased from 3s. to 4s. per cwt. of manufactured sugar from 1st January, 1907, to 1st January, 1913, provided that the excise duty payable on sugar produced from cane delivered for manufacture in 1911 and 1912 shall be two-thirds and one-third of the above rate respectively. [T.R.]

UNITED STATES PATENT.

Starch; Process of preparing soluble ——. A. F. J. S. and H. A. R. A. Haake, Hamburg, Germany. U.S. Pat. 813,647, Feb. 27, 1906.

SEE Eng. Pat. 885 of 1903; this J., 1903, 754.—T. F. B.

FRENCH PATENTS.

Sugar; Process of refining ——. K. Dorant. Fr. Pat. 358,659, Oct. 19, 1905.

RAW sugar of good quality is treated with a limited, predetermined quantity of water so that the exterior portions only of the crystals are dissolved, whilst the central portions remain undissolved. It is stated that in this manner the

whole of the impurities are obtained in the melted syrup, and that the undissolved residue consists of perfectly pure sugar. The syrup is separated and refined in the usual manner, whilst the residual crystals are collected and used for making clairce syrup or for other purposes. —J. F. B.

Wood; Rotary digester for the saccharification of ——. Comp. indust. des alcools de l'Ardèche. Fr. Pat. 358,696, Oct. 20, 1905.

THE digestor for converting wood-wastes, such as sawdust, into fermentable sugar consists of a horizontal rotary cylinder with circular plates forming the two ends. The cylinder is mounted on a hollow shaft through which steam is supplied to a series of heating tubes disposed parallel to the axis and arranged at various distances from the same at points on circles concentric with the wall of the cylinder. The heating tubes project through the ends of the drum, and are connected by a radial steam pipe outside the digester with the central steam supply on the one side, and by a similar series of radial pipes with a central condensed water outlet on the other side. At the exit side of the apparatus each heating tube is provided with a cock, the handle of which is operated automatically by fixed pins placed at the highest point of rotation. Thus the heating pipes are opened for a moment and closed automatically during each revolution, so that the water which has condensed in the pipes is regularly discharged.—J. F. B.

Starches and dextrins; Manufacture of phonograph records from ——. Comp. gen. de phonographes, cinématographes et appareils de précision. First Addition, dated Oct. 10, 1905, to Fr. Pat. 358,366, Oct. 9, 1905 (this J. 1906, 227).

IN addition to starches and dextrins, other amylaceous materials, such as meals of cereals and leguminous seeds or glutens may be employed for moulding discs and cylinders. An addition of formaldehyde, tannin, gallic acid or salicylic acid may be used with advantage for antiseptic purposes. A better agglutination may be obtained by mixing sodium carbonate, alumina or magnesia or their salts with the starchy materials employed. —J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

(*Continued from page* 230.)

Fungi [*Glœosporium*]; *Formation of sporulating yeast-like forms of* ——. P. Viala and P. Pacottet. Comptes rend., 1906, **142**, 458—461.

THE formation of endogenous spores similar to ascospores has been regarded as a characteristic of true yeasts and mycoderma, serving to distinguish them from the yeast-like forms of the filamentous mould fungi. The authors' studies on the parasitic fungi which cause the anthracnosis of the vine and the plane tree (species of *Glœosporium*), show, however, that these fungi also possess this property. In saccharine media the fine, filamentous mycelium soon becomes divided by cross walls and breaks up after a time into cells which multiply by budding like yeasts, and continue to do so when transplanted to fresh media. These cells stand morphologically midway between those of *S. apiculatus* and *S. ellipsoideus*; they produce small quantities of alcohol, and form endospores under the same conditions as the true Saccharomycetes. These yeast-like cells can be slowly re-transformed into the original mould fungus by suitable treatment. This observation re-opens the question enunciated by Pasteur, whether the wild and industrial yeasts are not really forms originally derived from mould fungi, which have become fixed more or less permanently in their present state.—J. F. B.

Yeast species; Influence of formaldehyde on the reproductive energy, the fermentative energy and the generation period of various ——. J. Hirsch. Allg. Z. Bierbrau u. Malzfab., 1905, **33**, 351; Z. ges. Brauw., 1906, **29**, 118.

VARIOUS species of yeast, including Saaz, Frohberg and Logos culture yeasts and certain wild yeasts, were digested for one hour at 20° C. with varying proportions of commercial formalin; the yeasts were then separated in a centrifugal machine and stirred up with water, and known quantities of cells were cultivated in a medium composed of cane sugar and yeast water. Very small quantities of formaldehyde were found to have a stimulating influence on the reproductive energies of the yeasts at 3° C., with the exception of Saaz yeast. As a general rule the fermentative energies reached their maximum points when the reproductive energies were beginning to be affected adversely. As soon as reproduction and fermentation began to be inhibited by the increasing proportions of formaldehyde employed, the invertive power of the yeasts towards cane sugar rose considerably, the increase in the case of Frohberg yeast being very marked. Formaldehyde does not hinder the secretion of invertase. The proportions of formaldehyde per 100 c.c. of wort which were required to kill the yeast cells varied according to the species; thus, for Frohberg and Logos yeasts 4·5 mgrms. of formaldehyde were necessary; for *S. Pastorianus III.*, 3·1 mgrms.; for Saaz yeast and *S. ellipsoideus I.*, 2·8 mgrms. The time of action necessary for the death of all the cells varied with the temperature; in the case of Frohberg yeast the necessary duration of action was 30 minutes at 18° C., 45 minutes at 25° C., and 35 minutes at 37° C. As regards the generation period the culture yeasts were more resistant to formaldehyde than the wild yeasts; very small doses of formaldehyde shortened the period between one generation and the next.—J. F. B.

Ozone; Physiological action of —— *on* [*Organisms*]. W. Sigmund. Centrabl. Bakt. II., 1905, **14**, 400; Z. ges. Brauw, 1906, **29**, 133—134.

THE author has studied the action of ozone on enzymes, fermentative processes and bacteria. All the enzymes studied, *viz.*, diastase, emulsin, pepsin, invertase, ptyalin, pancreatin and rennet, suffered a decrease in their activity, which differed in degree not only with the different enzymes but also with one and the same enzyme. The degree of inhibition was found to depend on the quantity of ozone, on the velocity of the current of ozonised air or oxygen, and on the time of action, also on the degree of purity of the enzyme and on the concentration and quantity of the enzyme solution. A destruction of the diastase in 50 c.c. of malt extract was effected in six hours by the passage of a current of ozonised air at a velocity of 1·5 litre per hour, the proportion of ozone (O_3) in the air being 1 mgrm. per litre, *i.e.*, a total quantity of 9 mgrms. of ozone. The action of ozone on invertase in more dilute solutions was more intense. The fermentative power of yeast was distinctly weakened by the action of ozone to an extent varying greatly with the intensity of ozonisation. Small quantities of ozone had a relatively slight effect on the fermentative power, corresponding to the large proportion of organic matter contained in the yeast, and which had first to be acted on; larger quantities of ozone lowered the fermentative power considerably, at all events when measured by the action on cane sugar. In none of these experiments was the combined fermentative power of the yeast towards cane sugar [invertase and zymase] destroyed completely. As regards the influence of ozone on acetification, excluding the direct oxidation of the alcohol by the ozone, it was found, under the conditions studied, that the development and activity of the acetifying bacteria were only temporarily weakened or delayed; the bacteria rapidly recovered and then seemed to possess a slightly increased activity as compared with untreated bacteria.—J. F. B.

Vinegar factories; Pure cultivated bacteria in ——. W. Henneberg. Centralbl. Bakt. [Abth. 2], 1905, **14**, 661; Z. ges. Brauw., 1906, **29**, 117.

HITHERTO the employment of pure cultures of acetifying bacteria has not been applied in vinegar making by the German "quick-vinegar" process. The author has, however, now isolated two species of these bacteria, and has been working one of them on an industrial scale for three months. The vinegar is produced at a strength of 11·5 per cent. and is perfectly clear and rich in bouquet. The culture is being supplied to the factories working the

"quick vinegar" process for the purpose of starting their acetifiers. The author is also preparing pure cultures of wine-vinegar bacteria for similar purposes.—J. F. B.

Malting industry of Germany. Bd. of Trade J., March 8, 1906.

THE quantity of barley and other grain used for brewing purposes in Germany amounted to 796,408 tons in 1901, 745,805 tons in 1902, and 771,169 tons in 1905. Malt substitutes used in Germany (such substitutes are illegal in Bavaria) amounted to 14,962 tons in 1901, 13,444 tons in 1902, and 13,665 tons in 1903.

The hops grown in the German Empire in 1905 amounted to 607,000 centners. In Germany hops are, in most instances, not sufficiently dried till they pass into the hands of the dealer, who puts them into the required condition. In some instances hops are sent out sun- or air-dried for immediate use to local brewers.

[T.R.]

ENGLISH PATENTS.

Diastase; Production of pure ——. S. Fränkel, Strassburg, Germany. Eng. Pat. 5845, March 20, 1905.

A COLD water extract of malt is sterilised by filtration through a clay or other suitable filter; it is then fermented by a pure culture of Logos or Frohberg yeast, preferably under vacuum. The yeast ferments the sugars and higher carbohydrates, and removes a large proportion of the nitrogenous matters from the solution, but does not diminish the diastatic power. The fermented liquid is filtered and evaporated at a low temperature *in vacuo*; the product is finally freed from all dialysable bodies and is dried by evaporation *in vacuo*.—J. F. B.

Brewing and other purposes; Manufacture from grain of material for use in ——. E. C. Schrottky, Calcutta. Eng. Pat. 21,754, Oct. 25, 1905.

RAW or previously steamed grain is treated with a glucose solution and pressed brewers' yeast in the proportion of about 4 parts of each constituent per 100 parts of grain. The mixture is fermented at about 115° F. for two to three days, drained, and the grain washed with water at 120° F., again drained and covered over. Here it remains for two days at 120°—150° F. The grain is then either steamed for use or dried. Such modified grain is mashed with malt for brewing purposes, or employed for the preparation of food products. (See also Eng. Pat. 23,277 of 1904; this J., 1905, 1248.)—J. F. B.

(A.)—FOODS.

Silk-fibroin; Formation of a dipeptide by the hydrolysis of ——. E. Fischer and E. Abderhalden. Ber., 1906, **39**, 752—760.

SILK-FIBROIN was treated with an excess of 70 per cent. sulphuric acid for five days at 18° C., the solution was freed from sulphuric acid and concentrated under reduced pressure. For purification, the product was digested for eight days with active pancreatic juice, and the tyrosine so produced was removed by crystallisation. For the separation of the dipeptides from the amino-acids, advantage was taken of the ease with which the ethylic esters of the latter are volatilised. The product, after the removal of the tyrosine, was esterified by the action of alcohol and gaseous hydrogen chloride. When the alcoholic solution was distilled, the esters of the amino-acids, mainly glycocol and alanine, were removed in the distillate. The residue was treated with dry ammonia gas to convert the dipeptides into the diketopiperazine derivatives, which are readily crystallisable. In this manner the authors obtained a fairly high yield of a dipeptide derivative identical with glycyl *d*-alanine anhydride prepared synthetically. This anhydride was split up on hydrolysis into a mixture of glycyl-*d*-alanine and *d*-alanyl-glycine and may have been derived from either of these dipeptides in the crude product. There is reason, however, to believe that the dipeptides produced by the hydrolysis of silk fibroin consist mainly of glycyl-*d*-alanine, since alanyl-glycine does not resist the action of pancreatic juice; a small quantity of glycyl-tyrosine was also found. Hydrolysis of silk by concentrated hydrochloric acid yielded the same product as was obtained by the action of sulphuric acid.—J. F. B.

Cocolio. U.S. Customs Decision, Dec. 26, 1905.

AN article invoiced as cocolio, prepared from cocoanut oil, and used as an edible fat, is dutiable at 3½ c. per lb. as "cocoa butterine." Other cocoanut oil products were held to be either dutiable as above stated when fit for food, or free of duty as "cocoanut oil" when suitable for soap making. [T.R.] R. W. M.

Albumin from vegetable substances; Process for extracting ——. F. W. Gaertner, Niagara Falls, N.Y. U.S. Pat. 813,373, Feb. 20, 1906.

VEGETABLE substances in the form of meal are digested with seven to ten times their weight of a solution of salt containing about 3·5 per cent. of salt, at a temperature of 30°—40° C. for about five hours, in order to extract the albumin. The solution is then filtered and boiled, and the coagulated albumin is collected and dried. The albumin so obtained is ground and bleached by means of a solution containing about 12 lb. of sodium peroxide, and 16 lb. of sulphuric acid per 100 galls., together with a little alkali. The bleached albumin is then washed, dried and ground to a fine powder.—J. F. B.

GERMAN PATENT.

Milk powder from whole milk; Preparation of —— H. J. Bucka, C. Hansen, and O. B. Wimmer. Ger. Pat. 164,795, May 26, 1901.

THE milk is evaporated first, *in vacuo*, in the ordinary manner, with continual agitation, until it contains from 25 to 30 per cent. of water, and then, with access of air, at a temperature below the melting point of the milk-fat until the water-content is reduced to 16—20 per cent. The evaporated milk is now powdered and further dried at the temperature mentioned, until a product containing not more than 14 per cent. of water is obtained. It is stated that in this way a milk powder is produced in which the fat is present in the form of small globules, surrounded by dried "blue milk," which prevents the fat from decomposing.—A. S.

(*B.*)—SANITATION; WATER PURIFICATION.

Sewage, A study of the process of nitrification with reference to the purification of ——. H. Chick. Roy. Soc. Proc. 1906, 77 B, 241—266.

THE objects of the present research were mainly the chemical study of the course of the nitrification occurring during the filtration of sewage, the isolation of the organisms concerned, and the study of the question of absorption of ammonia upon the surface of filtering material previous to nitrification. The investigations were carried out in Vienna and in Munich. The results obtained show that nitrification of ammonia occurs in two stages, and is due to the activity of two classes of bacteria, one producing nitrites and the second oxidising the nitrites to nitrates. The organisms belong to the same group as those concerned with nitrification in soils. That organisms so susceptible to the presence of organic matter are able to live and do their work in sewage filters may be explained by the fact that they are protected, to a certain extent, by the presence of other organisms, which view is strengthened by experimental results. The nitrifying organisms, moreover, probably live and multiply low down in the filter where the amount of organic matter is small, as porous materials, such as coke, &c., are able to retain upon their surface complicated organic substances of high molecular weight, when these are presented in solution. The nitrifying bacteria are doubtless present in very great numbers in the filters, and this may also assist them in withstanding the effect of organic matter. Experiments by other observers have shown that nitrifying organisms, if present in sufficient quantity, live in the presence of amounts of organic matter otherwise inhibiting them.

In the maturing of filters, the two stages of nitrification may be markedly separate in time, or may both develope together. This difference is reciprocally related to the greater or less ammoniacal content of the sewage. In experiments with strong sewage the inhibitory action of abundance of ammoniacal compounds presumably retarded the development of the nitrate-producer, until the nitrite-producer was sufficiently well established to be converting most of the ammonia into nitrites. There is no evidence of absorption of free and saline ammonia in coke filters without contemporaneous nitrification, and the author considers the process of nitrification, during the filtration of sewage through such filters, to be an extremely rapid biological process, requiring for its completion only the time taken for the liquid to pass through the filter (three hours or so). Temperature is shown to have a marked influence on the oxidation of sewage, a higher temperature being noticeably more favourable.

The previous conclusions are chiefly drawn from experiments with continuous filters, but filters working as contact beds were also investigated, and found to be less efficient. The advantages of the continuous method would seem to lie in the much more complete aeration and efficient diffusion, and also in the stratified distribution in the filter of the different stages of the purification. Simple mechanical treatment would meet any difficulties due to clogging which might be met with in the practical employment of continuous filters, as it would probably occur in the superficial layers of the filter bed. In the case of contact beds, however, clogging necessitates the cleansing of the whole bed. The method of continuous filtration would, therefore, appear to be the most advantageous method of purifying sewage.—W. P. S.

Sulphates; Determination of —— in drinking waters. F. Raschig. XXIII., page 286.

ENGLISH PATENTS.

Sewage, trade effluents, and other foul or polluted waters; Treatment of ——. H. Spivey, Heckmondwike, Yorks. Eng. Pat. 12,481, June 16, 1905.

THE sewage is passed into a closed tank, the upper part of which is separated from the lower by a gauze partition, forming a chamber which is filled with filtering material such as coke, shingle, charcoal or the like. The liquid portion of the sewage is forced through this filter by the head of water behind it, and is then conducted to a second similar tank, and so on until it is sufficiently clear. The solids contained in the sewage collect at the bottom of the tank or tanks, whence they are conveyed by a rotating scraper into a vertical screw conveyor by which they are raised above the level of the sewage admitted to the tank and then discharged. The filtering material may be periodically cleansed by forcing water through it from the top at a high pressure, a valve being provided for this purpose.—W. P. S.

Water or other liquids; Apparatus for the treatment of —— with powdered materials. Maignen's "Filtre Rapide" and "Anti-Calcaire" Co., Ltd., and A. A. Ellis, London. Eng. Pat. 15,527, July 28, 1905.

IN water-softening apparatus, in which powdered materials are fed into the water from a reservoir by means of blades rotated in the reservoir by a water-wheel which is turned by the flow of the water to be treated; it has been found that, as the supply of powder in the reservoir decreases, the resistance offered to the motion of the wheel is lessened. The result is, that for the same rate of flow, the wheel moves faster and the proportion of the powder to the water is increased. To overcome this defect, the opening by which the powder leaves the reservoir is slowly closed by a slide. An eccentric placed on the shaft of the water-wheel, imparts a reciprocating motion to a rocking lever,

which in turn actuates a pawl, and rotates a toothed wheel. The motion of the latter, after being geared down, operates a screw which slowly closes the slide. When the reservoir has to be refilled, the slide is opened again and the whole operation is repeated.—W. H. C.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page* 232.)

ENGLISH PATENTS.

Paper-making apparatus. A. J. Boult, London. From O. Moritz, Pasing, Germany, and T. Moritz, Schlöglmühl, Austria. Eng. Pat. 10,880, May 24, 1905.

WHEN the width of the paper which is being made, is less than the full width of the travelling machine wire, an adjustment of the width of the suction boxes is necessary in order to prevent air being drawn through the uncovered portions of the wire. According to this invention two bands of flexible material are provided above each side of the suction box, these bands passing over pulleys capable of being moved nearer to or further from the centre of the machine, after the manner of deckle straps. The flexible bands are kept, by the suction, in intimate contact with the portions of the travelling band uncovered by paper and make a tight joint between the edge of the paper and the edge of the suction box. —J. F. B.

Pulps; Production of white —— from natural vegetable matter or from coloured or dyed waste material for use in Paper making. A. Gagedois, Donn, France. Eng. Pat. 14,385, July 12, 1905.

SEE Addition of Oct. 17, 1904, to Fr. Pat. 306,278 of 1900; this J., 1905, 344.—T. F. B.

Paper, textile fabrics or the like; Coating —— with viscose or mixtures thereof with pigments, and apparatus therefor. L. Lilienfeld and V. Tedesko. Eng. Pat. 5214, March 13, 1905. VI., page 263.

UNITED STATES PATENTS.

Fibre from cornstalks and analogous pithy plants; Process of preparing ——. A. G. Manns, Assignor to Food and Fibre Products Co., Chicago, Ill. U.S. Pat. 811,419, Jan. 30, 1906.

CORNSTALKS, bagasse and analogous pithy plants are first treated with hot water or steam to remove soluble constituents, and then disintegrated by digestion under pressure with a "suitable hot reducing liquor" sufficiently drastic to effect moderately rapid disintegration of the pith and filamentary cells and their separation from the connective tissue but not drastic enough to destroy them, except to a small extent. The fibre is then mechanically separated from the liquor and finally beaten.—E. F.

Cellulose solution. E. W. Friedrich, Blaton, Belgium. U.S. Pat. 813,878, Feb. 27, 1906.

SEE Fr. Pat. 357,171 of 1905; this J., 1906, 88.—T. F. B.

FRENCH PATENT.

Paper; Process for producing irregularly shaded ——. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 350,447, Oct. 31, 1904.

GERMAN PATENT.

Electrodes of alkaline accumulators; Employment of cellulose derivatives for the separation of the ——. Kölner Akkumulatorenwerke Gottfried Hagen. Ger. Pat. 165,233, Aug. 3, 1904. XI*A*., page 271.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 233.)

Veratrum album; Alkaloids of the rhizome of —— and quantitative determination of the same. G. Bredemann. Apoth.-Zeit., 1906, **21**, 41—45, 53—56. Chem. Centr., 1906, **1**, 606—608.

THE rhizome of *Veratrum album* contain quantities of total alkaloids varying from 0·19928 to 0·9328 per cent For the determination of the total alkaloids, 12 grms. of the powdered rhizome were shaken with 120 c.c. of a mixture of equal volumes of ether and chloroform, 10 c.c. of sodium hydroxide solution added, the mixture allowed to stand for three hours with frequent agitation, and then sufficient water to cause the powder to agglomerate. After allowing to settle, the ether-chloroform solution was poured off, clarified by means of calcined magnesia and three or four drops of water, and 100 c.c. filtered off. The filtrate was shaken three times with 10 c.c. of water acidified with acetic acid, and the united extracts were made alkaline, and then shaken out three times with the ether-chloroform mixture. The solution so obtained was evaporated to dryness, and the residue dried at 100° C. and weighed.

For the separation of the different alkaloids, a solution of the total alkaloids in water acidified with acetic acid, was prepared from 5 kilos. of the coarsely-powdered rhizome, in essentially the same manner as in the determination of the total alkaloids, and this aqueous solution treated according to the metaphosphoric acid process of Salzberger (Arch. Pharm., **228**, 462). The precipitate consisting of jervine and rubijervine was washed, the filtrate made strongly alkaline with ammonia, and extracted successively with ether and chloroform, which removed protoveratrine and pseudojervine respectively.

Jervine, $C_{26}H_{37}O_3N,2H_2O$, forms white acicular prisms, resembling morphine sulphate crystals; after drying, it melts at 241° C.; it is easily soluble in chloroform, moderately in alcohol, slightly soluble in ether, and almost insoluble in benzene and petroleum ether. *Rubijervine*, $C_{26}H_{43}O_2N,H_2O$, forms acicular prisms melting at 234° C., moderately soluble in hot chloroform, less soluble in alcohol, and slightly soluble in ether and petroleum ether. *Pseudojervine*, $C_{29}H_{43}O_7N$, crystallises in thin hexagonal plates, melting at 304° C., easily soluble in chloroform, slightly soluble in alcohol, almost insoluble in ether, petroleum ether and benzene. *Protoveratrine* forms small colourless, square or hexagonal plates, moderately soluble in chloroform and hot absolute alcohol, slightly soluble in cold ether, insoluble in benzene, water and petroleum ether. From the mother-liquor from protoveratrine, the author isolated a small quantity of a base (m. pt. 230°—241° C.), which crystallised from absolute alcohol in white needles grouped together in the form of balls.—A. S.

Cocaine; Action of bromine on ——. A. W. K. de Jong. Rec. trav. chim. Pays-Bas., 1905, **25**, 7. Chem. Centr., 1906, **1**, 705.

ON shaking together aqueous solutions of cocaine and bromine, or by mixing together carbon tetrachloride solutions of the two substances, and then shaking with water, a crystallisable orange-yellow oil is obtained. The crystals are soluble in ethyl acetate, insoluble in water and ether, and slightly soluble in carbon tetrachloride. They diminish in volume at 75° C., and melt at 85° C. The compound appears to have the composition, $C_{17}H_{21}O_4NHBr.Br_2$; it easily loses bromine, and on heating with water, dissolves, with formation of cocaine hydrobromide. Cinnamylcocaine yields a similar derivative with bromine.—A. S.

Kolatin: A new glucoside from kola nuts. Goris Bull. commercial, 1905, **33**, 563.

THE fresh seeds of *Sterculia kola*, besides the kolanin of Knebel, contain another glucoside, kolatin, which forms white prismatic acicular crystals, m. pt. 150° C. The

yield is from 0·3 to 0·4 per cent. The new compound is fairly soluble in water, more so in alcohol, acetone, and ethyl acetate, less so in ether, and is almost insoluble in chloroform, even when boiled therein. It is hydrolysed by sulphuric acid into dextrose, and a substance with the characters of a phenol. The latter gives a green colour reaction with ferric chloride, and is slowly coloured orange-yellow by ammonia.—J. O. B.

Lycopodium; New adulterant of ——. C. Gallois. J. Pharm. Chim., 1906, **23**, 242—244.

THE product obtained by the action of anhydrous ammonia on dry (Austrian ?) galipot resin, at a temperature near the melting point of the resin, is employed when powdered, as an adulterant of lycopodium. The admixture is not readily detected by superficial examination, and the powder flashes in the flame like the genuine drug. It is slightly soluble in alcohol, in ether and in chloroform, these solvents removing resinous matter. Pure lycopodium yields practically nothing to the same solvents. Microscopical examination at once shows that the adulterant is in the form of irregular transparent grains, with rounded angles; under the lens it is quite distinct in appearance from the characteristic spores of which lycopodium is composed.—J. O. B.

Lichens and their characteristic constituents. O. Hesse. J. prakt. Chem., 1906, **73**, 113—176.

THE author has examined the following varieties:—*Usnea longissima. Ach., Usnea barbata, var. hirta* from San Thomé (West Coast of Africa) and Sothupara (Madras), *Usnea barbata var. florida* (Hoffm.), *Alectoria implexa* (Hoffm.), *Cornicularia aculeata* (Körber), *Rocella phycopsis* (Ach.), *Rocella peruensis* (Krempelhuber) = *R. fruticosa*, Laurer = *R. cacticola* (Darbishire), *Cetraria islandica* (*L.*), including varieties from the Cavalljoch (Vorarlberg) and the Stubaital (Tyrol). A description of triethylprotocetraric acid (cetraric acid) is here given. *Parmelia tinctorum* (Despreaux), *Parmelia conspersa* (Ehrh.), *Xanthoria lychnea* (Ach.), *Gasparrinia elegans* (Lk.) Tornab. *Ochrolechia pallescens* γ. *parella* (Mass.) = *Lecanora parella* (*L.*), *Pertusaria lactea*, Nyl. *Humatomma coccineum var.* ? *Pulveraria chlorina* Ach. = *Lepraria* (*Lepra*) *chlorina* Ach. *Lepraria latebrarum* Ach. The investigation concludes with a description of parellic acid and a list of the lichens in which it is found.—F. SHDN.

Terpenes and essential oils. 76th and *77th Communications.* O. Wallach. Annalen, 1906, **345**, 127—138, 139—154.

THE 76th communication deals with new compounds obtained from β-terpineol, the work being treated under the following headings:—Action of sodium methylate on β-terpineol-nitrosochloride; the aldehyde, $C_{10}H_{14}O$; the ketone, $C_{10}H_{14}O$.

In the 77th communication the preparation of some new heptacyclic compounds is described, *viz.*, Δ′-Methylsuberene [Δ′-methyl-(1)-cycloheptene], C_8H_{14}; methylsuberanmethoxyloxime; methylsuberenone; methyl-(1)-cycloheptanone-(2)(methylsuberone); methene-cycloheptamethylene (methenesuberene); glycol from methenesuberene: suberanaldehyde; hydroxysuberancarboxylic acid; nitrosochloride from methenesuberene.—A. S.

Citronella and lemongrass oils; Ceylon ——. C. E. Sage. Chem. and Drug., 1906, **68**, 355.

THE author has examined samples of citronella and lemongrass oils distilled at the Government Experiment Station, Peradeniya, Ceylon.

Citronella oil.—The oil was of a dark orange colour, and had the following characters:—Sp. gr. at 15·5° C., 0·884; optical rotation, —3·3°; citronellal, 36 per cent.; geraniol 41 per cent.; Schimmel's test (see this J., 1904, 886), turbid solution. The fact that the oil failed to pass Schimmel's test points to the desirability of rejecting that test as a criterion of purity for citronella oil, which should be judged by its content of odorous constituents, namely, geraniol and citronellal.

Lemongrass oil.—The sample of oil examined had the sp. gr. at 15·5° C., 0·899; aldehydes (calculated as citral), 66·5 per cent.; optical rotation, —0·2°. It was not completely soluble in ten parts of 70, 80, or 90 per cent. alcohol, but formed a clear solution with an equal volume of absolute alcohol, the solution becoming turbid, however, on addition of more alcohol. The oil possessed a finer odour than East Indian lemongrass oil.—A. S.

Essential oils; New —— [*Ocotea usambarensis Engl., and Piper Volkensii, C.D.C.*]. R. Schmidt and K. Weilinger. Ber., 1906, **39**, 652—658.

THE essential oil from *Ocotea usambarensis* Engl. is found to the extent of about 0·15 per cent. in the bark. It is a thin oil of a yellow colour and a strong smell indicating the presence of cineol. It boils between 50° and 160° C. at 10 mm., sp. gr. at 20° C., 0·913; $n_D = 1·476$; α_D at 20° C. = —11° 12′; acid value, 1·2; ester value, 12·5. The following are the principal constituents:—Myristic aldehyde, 1 per cent.; cineol, 40 per cent.; *l*-terpineol, 40 per cent.; sesquiterpene, $C_{15}H_{24}$ or $C_{15}H_{26}$, 10 per cent.; esters, 4 per cent.; traces of a ketone (semi-carbazone, m. pt. 197° C.), and small quantities of terpenes.

The leaves of *Piper Volkensii*, C.D.C., contain 0·3 per cent. of an oil. This has a light brown colour and a strong but pleasant smell. It distils over almost entirely between 90° and 175° C. at 12 mm. Sp. gr. at 20° C., 0·934; $n_D = 1·5017$; $\alpha_D = -8° 24′$; ester value, 17; after acetylating, the ester value is 66. This latter is due to the presence of 14 per cent. of an alcohol, most probably citronellol. 70 per cent. of the saponified oil distilled between 135° and 148° C. at 15 mm. One-third of this fraction consisted of limene. The remainder appeared to be a methoxylated safrol, $C_{11}H_{12}O_3$. Its bromine addition compound melted at 122° C., and the original substance on regeneration boiled at 136°—140° C.; with sp. gr. at 20° C., 1·137; and $n_D = 1·5416$.—F. SHDN.

Carline thistle (*Carlina acaulis L.*); *Essential oil from* ——. F. W. Semmler. Ber., 1906, **39**, 726—731.

THE dried roots of *Carlina acaulis* yield about 2 per cent. of a heavy oil, with sp. gr. 1·0333 at 19° C.; $n_D = 1·56960$. The constituents were isolated by fractional distillation. The first constituent, amounting to 12—15 per cent. was *carlinene*, $C_{15}H_{24}$, boiling between 139° and 141° C., with sp. gr. 0·8733 at 23·8° C., and $n_D = 1·492$. These figures show carlinene to be a monocyclic, doubly unsaturated sesquiterpene. A small quantity of palmitic acid was isolated. The chief constituent is *carlina-oxide*, $C_{13}H_{10}O$, b. pt., 167°—168° C., sp. gr., 1·066 at 17° C., $n_D = 1·586$, and optically inactive. It is reduced by sodium and alcohol to tetrahydrocarlina-oxide, $C_{13}H_{14}O$, boiling at about 135° C. at 10 mm., and at about 262° C. at ordinary pressure. This product was identical with 1-phenyl-3-*a*-furyl-propane prepared synthetically, thus indicating the relative position of the carbon atoms in carlina-oxide.
—F. SHDN.

Aniseed Oil; New method of extracting ——. P. Eberhardt. Comptes rend., 1906, **142**, 407—408.

THE author finds that aniseed oil is yielded not only by the fruit, but by the leaves of the plant. The oldest leaves are gathered in the middle of the dry season and distilled with water. This does not exhaust the plant, and forms a definite addition to the yield of oil. The oil has a slightly lower solidifying point than that from the seeds, but is essentially the same substance.—J. T. D.

Acetamide; Preparation of ——. F. M. François. J. Pharm. Chim., 1906, **23**, 230—237.

THE following method gives a yield of 91·7 per cent. of the theoretical quantity of pure acetamide, compared with 28·1 per cent. obtained by the process of Roorda Smit. (Bull. Soc. Chim., 1875, **24**, 539), 1060 grms. of hard, transparent ammonium sesquicarbonate are heated on the water-bath, in a large flask, with 2000 grms. of glacial acetic acid, so as to obtain ammonium diacetate. The flask is then fitted with an earthenware stopper, pierced with three holes, and packed with asbestos fibre. One hole carries a safety tube; the second, a thermometer; and the third, a funnel-adapter, bent at an obtuse angle. All these fittings are

packed with asbestos, or luted over with plaster, and fixed with a strip of canvas saturated with gum. The bent adapter is then fitted to a sloping Liebig's condenser, having a wide inner tube and a narrow annular jacket. The lower lateral inflow tube is removed. The jacket is three-parts filled with acetic acid, b. pt. 118° C., instead of water, so as to form a condensing zone of higher boiling point than that of water; some pieces of pumice or charcoal are introduced into the acid to prevent bumping. The upper lateral outflow tube is attached to a long upright tube to serve as a condenser to keep the acid in the jacket at a constant level. The upper end of this condenser is then connected by means of a bent tube with a descending condenser, all joints being made with asbestos. The two condensers will then have the form of an inverted V. The ammonium diacetate is heated over a gas flame, distillation being regulated by the thermometer. Decomposition commences at 135°—140° C., when the distillate consists chiefly of water, with a little acetic acid; from 140° to 195° more acid, and less water is given off. When the temperature in the flask has reached 195° C., the condenser containing the acetic acid jacket is removed, and one containing dry aniline, b. pt. 183°, substituted for it. Distillation is then resumed, when the liquid which passes over between 195° and 222° contains some acetamide. As soon as the liquid in the flask has a constant b. pt. of 222° C., the process is stopped, for the residual product is pure, almost colourless acetamide. The acetic acid in the distillates may be used again in subsequent operations. The product of this method is purer than the acetamide obtained by distillation, having the constant b. pt. 222° C. to the last drop, any acetonitrile which is formed during the process being eliminated.—J. O. B.

Anilides; Influence of catalysers on the formation of ——. N. Menschutkin. Iswiestja d. Petersburger Polyt. Inst., 1905, **4**, 181—190. Chem. Centr., 1906, **1**, 551.

The author determined the rate of acetylation of aniline, *o*-, *p*- and *m*-toluidine and *m*- and *p*-xylidine both alone and in presence of different proportions of hydrochloric, hydrobromic and hydriodic acids. The method used was that of H. Goldschmidt and Wachs (Z. physik. Chem. **24**, 353). N/1-solutions of acetic acid in the respective amino compounds were treated with molecular proportions of the corresponding hydrochloride, hydrobromide, or hydriodide, and the mixtures heated at 182° C., the course of the reaction being followed by titration with barium hydroxide solution. It was found that in presence of the haloid acids, the reaction was unimolecular, but bimolecular when these acids were absent. The accelerating effect of the acids was directly proportional to the quantity present, hydriodic acid having the greatest influence and hydrochloric acid the least. In the case of the homologues of aniline the position of the methyl groups was of some importance, the rate of acetylation being retarded by the presence of a methyl group in the ortho position, but strongly accelerated by methyl groups in the meta and para positions.—A. S.

Chloral hydrate; Decomposition of — — under the influence of light and air. N. Schoorl and L. M. Van den Berg. Pharm. Weekblad, 1906, **43**, 42—47. Chem. Centr., 1906, **1**, 650.

Tubes containing (1) 1·060 grms. of chloral hydrate and 250 c.c. of oxygen, a quantity just sufficient for its complete oxidation, (2) 2 grms. of chloral hydrate and 250 c.c. of oxygen, and (3) 5 grms. of chloral hydrate, but from which the air had been previously exhausted, were exposed for several weeks to tropical sunlight, and then their contents examined. The results obtained indicate that under the influence of sunlight, in the absence of air, the decomposition of chloral hydrate alone proceeds according to the scheme: $CCl_3.CHO.H_2O \rightarrow 3HCl + 2CO$; in the presence of an insufficient quantity of oxygen for complete oxidation the following reaction also occurs: $CCl_3.CHO.H_2O + 2O \rightarrow 3HCl + 2CO_2$, or possibly, the chloral hydrate is decomposed as in the first case, whilst the carbon monoxide is further oxidised to carbon dioxide. When the amount of oxygen present is sufficient for complete oxidation, the products found indicate that the following reactions take place:—

$$CCl_3.CHO.H_2O + 2O \rightarrow 3HCl + 2CO_2,$$
$$2CCl_3.CHO.H_2O + 7O \rightarrow 3H_2O + 6Cl + 4CO_2,$$

but here again, the carbon dioxide, water and chlorine, may be due to the secondary oxidation of carbon monoxide and hydrochloric acid formed according to the first equation given above.—A. S.

Pharmaceutical substances; Influence of the incandescent gas light on some ——. N. Schoorl and L. M. Van den Berg. Pharm. Weekblad, 1906, **43**, 47—49. Chem. Centr., 1906, **1**, 696.

Different pharmaceutical substances contained in sealed tubes of white glass and of brown, so-called anactinic, glass, were exposed at about 40° C. to an incandescent gas light, at a distance of 10 cm., in a chamber protected from sunlight. The time of exposure amounted to 478 hours. Chloroform was not altered under any of the experimental conditions. Bromoform was not altered in the brown glass tubes, but in white glass it became yellow owing to separation of bromine, whilst the development of acidity indicated the formation of hydrobromic acid. Dry iodoform behaved in a similar manner to bromoform, some iodine being separated in the white glass tubes, but with a 5 per cent. alcoholic solution of iodoform, the decomposition was much more pronounced, both in the white glass and brown glass tubes; in the case of this alcoholic solution, decomposition was caused even at a distance of 2—3 m. from the source of light. From chloral hydrate, a small quantity of hydrochloric acid was formed. Resorcinol and pyrogallol suffered alteration only where the crystals were in contact with the glass, the change being caused by the combined action of the incandescent gas light and the alkali of the glass.—A. S.

Iodine; Distribution of —— between two solvents. Y. Osaka. Mem. Coll. Sci. and Eng., Kyoto, 1904—1905, **1**, 93—102. Science Abstracts, 1906, **9 A**, 119.

The distribution of iodine between two solvents, viz., aqueous alcohol and carbon bisulphide, at 25° C., was studied; with less than 47·9 per cent. of alcohol, the two solvents mentioned are practically immiscible. For a given mixture the ratio of distribution is independent of the iodine concentration and of the relative amounts of the two phases, and is nearly identical with the ratio of the solubilities of iodine in the two solvents separately. —A. S.

Bismuth; Some salts and complex salts of ——. A. Rosenheim and W. Vogelsang. Z. anorg. Chem., 1906, **48**, 205—216.

Bismuth tartrate-nitrate, $Bi(C_4H_4O_6)NO_3,5H_2O$. A solution of bismuth nitrate rendered faintly acid with nitric acid is treated with a concentrated solution of three molecular proportions of tartaric acid. After standing for some time, white prismatic crystals of bismuth tartrate-nitrate separate out. The compound is decomposed by water, with separation of a basic salt; in alkalis it dissolves to a clear solution. On adding it, in small portions, to a boiling solution of tartaric acid, it gradually dissolves, and on cooling, *bismuth bitartrate*, $Bi(C_4H_4O_6)C_4H_5O_6,2H_2O$, free from nitric acid, separates in the form of glistening needles. This salt is also decomposed by water with formation of a basic salt. *Potassium-bismuth tartrate*, $COOK.(CHOBiO)_2COOBiO,4H_2O$. This complex salt can be prepared by: (1) adding 3 mols. of crystallised bismuth nitrate in small portions to a solution of 2 mols. of tartaric acid and about 12 mols. of potassium hydroxide in five times their weight of water, and heating the mixture, when the compound separates as a micro-crystalline powder; (2) dissolving 1 mol. of bismuth bitartrate (see above) in a concentrated solution of 6 mols. of potassium hydroxide, and allowing the mixture to stand over sulphuric acid. The compound is easily soluble in water and alkalis. Another *potassium-bismuth tartrate*, corresponding to the formula,

can be obtained, although in poor yields, from a solution containing 1 mol. of tartaric acid, 1 mol. of bismuth nitrate, and 5 mols. of potassium hydroxide. After filtering, the solution is evaporated, separated from the potassium nitrate which crystallises out, and allowed to stand over sulphuric acid. The compound separates in crystalline scales, easily soluble in water. *Ammonium-bismuth tartrate*, of corresponding composition is prepared by dissolving bismuth bitartrate in excess of ammonia, and evaporating the solution, which is kept strongly alkaline by addition of ammonia. It is decomposed by water with separation of basic compounds. The following compounds have also been prepared by the author:—*Basic bismuth thiocyanate*, $Bi(OH)(CNS)_2,5H_2O$, from thiocyanic acid and excess of bismuth carbonate; *bismuth thiocyanate*, $Bi(CNS)_3,14H_2O$, from bismuth carbonate and excess of thiocyanic acid; *potassium-bismuth thiocyanate*, $K_3Bi(CNS)_6$, *sodium-bismuth thiocyanate*, $Na_3Bi(CNS)_6$, and *ammonium-bismuth thiocyanate*, $(NH_4)_3Bi(CNS)_6,5H_2O$, prepared by evaporating over sulphuric acid a solution of 1 grm.-mol. of bismuth carbonate, and about 6 grm.-mols. of alkali hydroxide or ammonia in excess of thiocyanic acid. *Bismuth acetate*, $Bi(C_2H_3O_2)_3$, may be obtained by boiling for two hours a mixture of 2 grm.-mols. of bismuth carbonate, 4 grm.-mols of mannitol, and 300 grms. of glacial acetic acid under a reflux condenser. The bismuth acetate crystallises from the cooled filtered solution in white scales.—A. S.

Mercurous iodide; New method of preparing ——. B. Szilard. Pharm. Centralh., 1906, **47**, 31.

A KNOWN weight of mercury is agitated with three times its volume of chloroform until globules disappear. An equivalent weight of iodine, previously dissolved in a large volume of chloroform, is slowly added with continuous agitation. Combination is almost instantaneous, and the greenish-yellow iodide is precipitated. A large volume of the solvent is necessary on account of the heat generated by the chemical action. The precipitate is collected by filtration, washed with boiling water, and dried in the dark. The chloroform filtrate may be employed again for the same process. The operation should preferably be conducted at night, to avoid the action of daylight on the chloroform-iodine solution, and on the mercurous iodide formed.—J. O. B.

Calcium iodomercurates. A. Duboin. Comptes rend., 1906, **142**, 395—398.

THE author has obtained by crystallisation at different temperatures from solutions of mercuric iodide in aqueous solution of calcium iodide, three salts, corresponding to the formulæ, $CaI_2.HgI_2.8H_2O$, $CaI_2.5HgI_2.8H_2O$, and $3CaI_2.4HgI_2.24H_2O$ respectively. These are distinguished by their crystalline form, but all yield insoluble compounds with many organic substances.—J. T. D.

Palladium; Colloidal nature of solution of — obtained by means of carbon monoxide. J. Donau. Monatsh. f. Chem., 1906, **27**, 71—74.

THE almost black solution obtained by passing carbon monoxide through the aqueous solution of a palladium salt has all the properties of a colloidal solution, and no doubt contains colloidal palladium.—J. T. D.

Hydrosulphides and thioacids; Volumetric determination of organic ——. P. Klason and T. Carlson. XXIII., page 287.

Carbonyl group in aldehydes, ketones, &c.; Quantitative determination of the ——. Watson Smith, jun. XXIII., page 286.

Paraldehyde. U.S. Customs Decision.

THE United States Circuit Court, Dec. 19, 1905, overruled a decision of the Board of General Appraisers which held that paraldehyde is dutiable at 55 cents per lb. as a "medicinal preparation in the preparation of which alcohol is used." The Court found that the aldehyde from which it is prepared is not derived from alcohol, but is one of the by-products resulting from the distillation of alcohol. The decision of the Court was that it is dutiable at 25 per cent. *ad valorem*, as a "medicinal preparation in the preparation of which alcohol is not used." The Treasury Department, Feb. 3, 1906, acquiesced in this decision.—R. W. M.

Safrol. U.S. Customs Decision, Jan. 30, 1906.

SAFROL is dutiable as a "distilled oil" under paragraph 3 of the tariff. —R. W. M.

Calisaya barks; Elixir of ——. U.S. Customs Decision, Jan. 26, 1906.

ASSESSMENT of duty was affirmed at 55 cents per lb. as "alcoholic medicinal preparations" under paragraph 67, on elixir of calisaya bark and elixir of calisaya bark and coca. The claim of the importer that they were dutiable at 2 dols. 25 c. per proof gallon as "alcoholic bitters," under paragraph 292, was overruled.—R. W. M.

ENGLISH PATENTS.

Theobromine; Compounds or salts of ——. F. Hoffmann-La Roche, Basel, Switzerland. Eng. Pat. 26,821, Dec. 22, 1905. Under Int. Conv., May 30, 1905.

SEE U.S. Pat. 799,764 of 1905; this J., 1905, 1082.—T. F. B.

GERMAN PATENTS.

Formaldehyde and formamide or acetamide; Process for preparing condensation products from ——. Kalle und Co., Act.-Ges. Ger. Pats. 164,610, Oct. 29, 1902, and 164,611, Nov. 15, 1902.

CONDENSATION products of the formula $R.NH.CH_2OH$ are obtained by heating formamide or acetamide with formaldehyde, preferably paraldehyde or trioxymethylene, without using a condensing agent. The products are stated to be of value as antiseptics and solvents for uric acid. If the heating be continued at a higher temperature, and particularly if 2 mols. of the acid amide are used to one of the polymerised formaldehyde, the product of condensation is methylenediformamide or methylenediacetamide.—T. F. B.

Dialkylbarbituric acids and their derivatives; Process of preparing ——. E. Merck. Ger. Pat. 163,200, March 18, 1904.

DIALKYLMALONAMINIC esters, $R_2C(CONH_2)COOK$, prepared by treating dialkylcyanoacetic esters with dilute sulphuric acid, are converted into dialkylbarbituric acids or their derivatives by condensation with urea, thiourea, or guanidine, in presence of alkaline condensing agents. —T. F. B.

Diethylmalonylcarbonyldiurea; Process of preparing ——. Chem. Fabr. von Heyden, Akt.-Ges. Ger. Pat. 165,224, July 16, 1904.

DIETHYLMALONIC esters are heated with carbonyldiurea,

$CO(NH.CO.NH_2)_2$, in presence of sodium ethylate or a similar condensing agent. The product does not yield diethylbarbituric acid when treated with 50 per cent. sulphuric acid, hence it is most probably a diethylmalonylcarbonyldiurea of the formula

$$CO:(NH.CO.NH.CO)_2:C(C_2H_5)_2.$$

—T. F. B.

Pseudoionone and its homologues; Process of preparing hydrates of ——. Knoll und Co. Ger. Pat. 164,366, May 19, 1904.

The sulphite compounds of pseudoionone or its derivatives are treated with acids (*e.g.*, sulphuric or oxalic acid, or an alkali bisulphate), when the hydrate of the sulphite compound appears to be formed. By treating these with alkalis, alkali sulphite and the hydrate of the pseudoionone derivative are formed. The hydrates are of value in perfumery.—T. F. B.

Hydrates of unsaturated organic compounds; Process of preparing ——. Knoll und Co. Ger. Pat. 165,726, Aug. 12, 1904. Addition to Ger. Pat. 164,366 (see preceding abstract).

Hydrates may be obtained from the sulphite derivatives of unsaturated organic compounds other than pseudoionone by the process described in the preceding patent. Thus hydrates of the following compounds may be prepared: — Citronellidene-acetone, carvone, citrylidene-malonic esters.—T. F. B.

Theobromine-barium and sodium salicylate; Process of preparing an easily soluble double salt of ——. Act.-Ges. f. Anilinfabr. Ger. Pat. 164,424, May 25, 1904.

Two mols. of sodium salicylate and either 1 mol. of the barium salt of theobromine, or 1 mol. each of the sodium salt of theobromine and of a soluble barium salt, are mixed in aqueous solution; on evaporating the solution the double salt is obtained in easily soluble condition. (Compare Eng. Pat. 4958 of 1905; this J., 1905, 1254.)

—T. F. B.

8-Aminotheobromine and its alkyl or aryl derivatives; Process of preparing ——. C. F. Boehringer und Soehne. Ger. Pat. 164,425, July 14, 1904. Addition to Ger. Pat. 156,900, Sept. 2, 1903. (See this J., 1905, 560.)

By treating 8-bromo- or 8-chlorotheobromine with ammonia or an aromatic or fatty amine, the corresponding derivative of 8-aminotheobromine is obtained.—T F.B.

Phenyldihydroquinazoline; Process of preparing a benzoyl derivative of ——. Kalle und Co., Akt.-Ges. Ger. Pat. 164,426, Aug. 7, 1904.

Phenyldihydroquinazoline is treated with benzoyl chloride, preferably in pyridine solution; the pyridine is decanted off, and the product washed with water and sodium carbonate solution, and again with water. It is stated to be of therapeutic value.—T. F. B.

Sulphur or selenium in colloidal, solid and permanent form; Process for the manufacture of preparations containing ——. Chem. Fabr. von Heyden, A.-G. Ger. Pat. 164,664, March 22, 1904.

Colloidal sulphur or selenium is separated by known methods, in the wet way, in presence of albumin, albuminoids or the products of hydrolysis or decomposition of the same; the solution is acidified, the precipitate filtered off, washed, redissolved in water with addition of sufficient alkali to render the liquid neutral or faintly alkaline, and the solution, after dialysis, evaporated or precipitated by an alcohol, a mixture of alcohol and ether, or acetone. For example, 10 parts of sodium sulphide are dissolved in 200 parts of water, and one part of albumin is dissolved in the solution by agitation. The sodium sulphide is then decomposed by passing sulphur dioxide into the solution. The precipitate is filtered off, washed, dissolved in water with the addition of a little alkali, and the solution dialysed and evaporated. The colloidal sulphur is obtained as a greyish-white, permanent, amorphous substance, dissolving in water to a milky liquid which has a bluish tint by reflected light.—A. S.

Luminous [Phosphorescent] bodies; Process for the preparation of ——. Chininfabr. Braunschweig Buchler und Co. Ger. Pat. 163,648, July 2, 1904.

Zinc sulphide is ignited and mixed with small quantities of manganese sulphide or copper sulphide. The product exhibits intense phosphorescence when exposed to light-, cathode-, Röntgen- or Becquerel-rays, or when subjected to mechanical pressure.—A. S.

United States Patents.

Explosive compound. R. Escales, Munich-Schwabing, Germany. U.S. Pat. 812,195, Feb. 13, 1906.

This patent is for an explosive composition, consisting of an oxygen carrier, such as ammonium nitrate, and an easily oxidisable metal in the form of "metal wool," such as aluminium wool.—W. C. H.

Explosive. F. Sparre, Assignor to the E. I. Du Pont de Nemours Powder Company, Wilmington, Del. U.S. Pat. 812,958, Feb. 20, 1906.

Claim is made for explosives containing ammonium nitrate, a metallic ingredient and ungelatinised nitrocellulose, with or without the addition of a liquid hydrocarbon as kerosene, the whole being compressed if so desired. Mixtures are specified containing ammonium nitrate, a metallic ingredient, and 5—25 per cent. of nitrocellulose with or without 10 per cent. of kerosene. The use of a mixture of ammonium nitrate, ferrosilicon, and nitrocellulose is also claimed.—B. J. S.

Explosive. F. Sparre, Assignor to the E. I. du Pont de Nemours Powder Company, Wilmington, Del. U.S. Pat. 812,959, Feb. 20, 1906.

The invention comprises explosives made from the following mixtures:—Ferrosilicon and nitroglycerin with (1) an oxygen carrier, or (2) ammonium nitrate, and, if desired, (*a*) a metallic ingredient, (*b*) kerosene, (*c*) kerosene and sodium nitrate, (*d*) kerosene and charcoal. A mixture of nitroglycerin with an oxygen carrier, a metallic ingredient, a liquid hydrocarbon and charcoal.—B. J. S.

Gunpowder, and process of making same. F. I. du Pont, Wilmington, Del. U.S. Pat. 813,020, Feb. 20, 1906.

Starch is added to the powdered ingredients for making

gunpowder in the proportion of 7—8 per cent. of the whole mass, which is mixed with 5—15 per cent. of water, then subjected to sufficient heat to swell the starch granules, and pressed into the required shape.—B. J. S.

FRENCH PATENT.

Nitroglycerin; Manufacture of ——. The Eastern Dynamite Co. Fr. Pat. 358,514, Oct. 14, 1905.

SEE U.S. Pat. 804,817 of 1905; this J., 1906, 199.—T.F.B.

UNITED STATES PATENT.

Gases; Apparatus for analysis of ——. A. Schlatter and L. Deutsch, Budapest, Austria-Hungary. U.S. Pat. 813,671, Feb. 27, 1906.

SEE Fr. Pat. 351,442 of 1905; this J., 1905, 904.—T. F. B.

INORGANIC—QUALITATIVE.

Schlagdenhaufen's reaction [for magnesium]; Modification of ——. L. Grimbert. J. Pharm. Chim., 1906, **23**, 237—239.

SCHLAGDENHAUFEN'S reaction for magnesium is best modified as follows:—To 10 c.c. of the liquid to be examined, 5 c.c. of 10 per cent. potassium iodide solution are added, followed by two or three drops of a strong solution of sodium hypochlorite. In the presence of magnesium, a reddish-brown flocculent precipitate will be formed, resembling ferric hydroxide in appearance. The reaction is very distinct with a dilution of 1:2000. It is essential that the solutions should be neutral, or but faintly alkaline; the least trace of free acid prevents the formation of the precipitate; an excess of alkali also renders the reaction less sensitive. Neither colour nor precipitate is given by lithium, nor by salts of the earthy metals.—J. O. B.

Arsenic from hydrochloric acid; Removal of ——, *for use in the Marsh-Berzelius method.* A. R. Ling and T. Rendle. Analyst, 1906, **31**, 37—38.

THE method described consists in boiling a mixture of hydrochloric acid of constant boiling point, and methyl alcohol in a reflux apparatus under reduced pressure with bright electrolytic copper free from arsenic, and then distilling the acid over similar copper. To 1,500 c.c. of commercial hydrochloric acid of a sp. gr. slightly above 1·1, about 40 c.c. of redistilled commercial wood-spirit are added, the mixture being contained in a Würtz flask of 2 litres capacity. About 5 grms. of arsenic-free granulated zinc are then added and the flask is connected with a reflux condenser by an ordinary cork, in which is fixed a glass rod supporting a coil of electrolytic copper foil, having a surface of about 120 sq. ins. The side tube of the flask having been plugged, the condenser is connected with an exhaust-pump, and the boiling commenced and continued for some hours, the copper being withdrawn and cleaned at least once during this period. It is advisable to interpose two vessels between the condenser and the pump. The first serves to collect a black tarry liquid which distils over, whilst the second flask contains a little water to absorb any hydrogen chloride which passes off. The acid is then distilled in presence of bright electrolytic copper.—W. P. S.

INORGANIC—QUANTITATIVE.

Pyrites; Determination of sulphur in ——. F. Raschig. Z. angew. Chem., 1906, **19**, 331—334.

THE author considers the benzidine method quite as accurate as the barium method, if not more so, provided due care be taken. He gives the following detailed directions for carrying out the process:—Exactly 0·8 grm. of the finely-powdered sample is weighed into a dry 200 c.c. conical flask, 5 c.c. of fuming nitric acid are added, and the flask heated on the water-bath with a small funnel in the neck. After half an hour 30 c.c. of water are added, and the whole contents are rinsed into a 100 c.c. flask, made up to the mark, and well shaken. Then 20 c.c. are placed in a 600 c.c. beaker, 10 c.c. of a 1 per cent. solution of hydroxylamine hydrochloride are added, and 500 c.c. of benzidine solution (this J., 1903, 1066). The liquid is well stirred and allowed to stand for 15 minutes, during which time the filter is prepared as directed, *loc. cit.* The bulk of the clear liquid is poured through the filter, and the precipitate brought on by about the last fifth of it, the last portions being rinsed on by means of some of the filtrate, or by benzidine solution from a wash-bottle. Water may be used, if not more than 10—20 c.c. be taken, and the washings be brought into the filter while still nearly full of liquid. The moment the water disappears from the surface of the precipitate the funnel is washed down with 5—10 c.c. of water, and this is followed by a second like quantity. As soon as this has disappeared, the pump is disconnected, so that the precipitate does not get felted together. The funnel is now removed, inclined at 45°, and the filter and plate overturned in the funnel by a rod pushed up from below. The plate is removed, the filter pressed together in the fingers, and dropped into a 250 c.c. conical flask with a neck 30 mm. wide, into which any precipitate adhering to the funnel is rinsed with not more than 25 c.c. of water. The flask is corked, the contents violently shaken till the precipitate is thoroughly broken up, the cork rinsed into the flask, nearly the requisite quantity of N/10 sodium hydroxide added (in this case, say, 40 c.c.), then about 2 c.c. of the usual phenolphthalein solution (this amount is needed because so much is absorbed by the filter paper). The flask is now heated till the red colour disappears, and then the titration proceeded with till the red colour is permanent on boiling. It should be destroyed by addition of a drop or two of N/10 hydrochloric acid, and not return on boiling for two minutes. The filtrate must always be tested with barium chloride, to make sure that enough benzidine solution has been used for complete precipitation. The method requires some practice, but the author states that when once expertness has been acquired in carrying it out, it will always be preferred to the barium method.—J. T. D.

Sulphates; Determination of —— *in drinking waters.* F. Raschig. Z. angew. Chem., 1906, **19**, 334.

To a quantity—½ to 5 litres—of the water is added one-twentieth of its volume of *strong* (this J., 1903, 1066) benzidine solution, and after 15 minutes the precipitate is filtered off and titrated as described in the method for pyrites (see preceding abstract). To the result, when expressed in milligrammes of sulphur trioxide per litre, 1·5 mgrms. are added, for the solubility of benzidine sulphate in the liquid. Should the water contain iron, 1—2 c.c. of hydroxylamine hydrochloride (1 per cent. solution) are added before precipitation.—J. T. D.

Metals, especially gold and palladium; Determination of —— *by electric conductivity measurements.* J. Donau. Monatsh. f. Chem., 1906, **27**, 59—70.

THE solution of the metal, very slightly acidified with hydrochloric acid, is placed in a U-tube constricted at the bend and furnished with a side-tube for the entry of carbon monoxide, and its conductivity is measured. Pure carbon monoxide is then led through, and the conductivity measured from time to time till it ceases to increase. The increase in conductivity is in the case of palladium directly proportional to the amount present; in the case of gold it is not so, but the connection between the two can be expressed by the formula:

$Z = 1{\cdot}76x - 0{\cdot}0237xy + 0{\cdot}0138x^2 - 0{\cdot}00111x^2y + 0{\cdot}000738xy^2$,

where Z = mgrms. of gold in 100 c.c. of the solution, and y and x are the original conductivity and increase in conductivity, respectively, expressed in the usual Kohlrausch units multiplied by 10^6.—J. T. D.

ORGANIC—QUANTITATIVE.

Halogens; Determination of the —— in organic compounds. W. Vaubel and O. Scheuer. Chem.-Zeit., 1906, **30**, 167—168.

THE method is based on the authors' observation that organic halogen compounds, on warming with concentrated sulphuric acid, part with their halogen as hydracid or as the free element. 0·2—0·5 grm. of the substance is weighed into a dry distilling flask of about 200 c.c. capacity, and 30—50 c.c. of concentrated sulphuric acid are added from a separating funnel fitted to the flask. Gentle heat is applied and the products are passed into a solution of silver nitrate. During or after the reaction a gentle stream of air is drawn through the apparatus. The silver halide may be weighed or the excess of silver nitrate titrated.

In cases where free halogen may be evolved, metallic copper or pure filter paper is added with the substance, in order to generate sulphur dioxide, and thus ensure the absence of oxyhaloid salts. The silver sulphite formed is decomposed by boiling with 50 c.c. of concentrated nitric acid, and any silver sulphate removed by thorough washing.

The method is not recommended for such volatile bodies as chloroform or chloral, but on account of its simplicity and rapidity, is well suited for the control of industrial operations and for routine work.—F. SODN.

Paraffin; Detection and determination of —— in mixtures with ceresin. F. Ulzer and F. Sommer. Chem.-Zeit., 1906, **30**, 142—143.

THE authors confirm the statement of Berlinerblau that the refractive power of paraffin decreases with its melting point and molecular weight, but they consider that the differences are not sufficiently great in practice to render the method valueless. Thus five different kinds of paraffins gave readings in the Zeiss butyro-refractometer of 1·5 to 4; and four representative ceresins readings of 11·5 to 13, at 90° C. Experiments were also made with Crismer's method (this J., 1895, 1069) of critical solution, different solvents being used. In alcohol, *e.g.*, four different paraffins gave values of 155° to 158° C.; the ceresins, 174° to 177° C.; carnauba wax, 144° C.; and montan wax, 57° C. A mixture of ceresin with 20 per cent. of paraffin gave a critical temperature of 170·3° C., and one containing 40 per cent. of paraffin gave 166·6° C. —C. A. M.

Malt analysis; Use of closed mashing beakers for ——. O. Pankrath. Z. ges. Brauw., 1906, **29**, 141—142.

THE determination of extract in malt is generally conducted in an open mashing beaker, but owing to the evaporation from the surface of the mash, the temperature inside the beaker remains 3°—5° C. lower than the temperature of the water-bath, and this difference of temperature, varying according to whether the mash is being stirred or not, makes it very difficult to control the process. The author has devised a lid of nickel-plated metal which is fitted to the ordinary mashing beaker, clipping it with a spring-rim. This lid carries a bearing through which passes a rotary stirrer; a tubulure near the side is also provided for the thermometer. The results of mashings conducted in this manner differ slightly from those obtained with open beakers. No appreciable differences are found in the extract values, but the time required for complete saccharification is distinctly shorter, and the odour of the mash is less aromatic in the case of closed beakers than with open ones. These differences are due to the presence of partially dried layers of mash formed at the surface and on the walls in the open beakers which take longer for saccharification and which develop a slightly burnt aroma in contact with the hot sides of the vessel.—J. F. B.

Worts and sugar solutions; Determination of extract in ——. H. van Laer. Bull. prat. du Brasseur, 1905, 1497; Woch. f. Brau., 1906, **23**, 90.

THE author comments on the method employed in England for determining the extract (grms. per 100 c.c.) in saccharine solutions. This consists in dividing the excess of gravity over 1000 by a divisor, the value of which is not universally settled, the normal temperature being 15·5° C. (60° F.). The divisor originally determined by O'Sullivan was 3·85; later this was changed to 3·86 by Brown and Heron. In 1897, Brown, Morris and Millar re-determined the value of the divisor for a large number of carbohydrates, and found that it varied with the concentration of the solutions, and, in the case of saccharified liquids, with the degree of saccharification. The present practice is to use the divisor 3·86 in the case of solutions of cane sugar, invert sugar and dextrose, introducing, however, a correction for the ash. In the case of worts, some chemists use a divisor of 3·95, whilst others use one of 4·00. The official German tables, based on K. Windisch's tables, correspond fairly closely with a divisor of 3·86. The author pleads for a uniform international system, based on the latter tables for all cases where the 3·86 divisor would be used by English chemists, since the difference between 15° C. and 60° F. would introduce no appreciable error. In the case of worts it is generally recognised that Windisch's tables give values which are too high. The author, therefore, advocates the standardisation of the English system, taking the sp. gr. at 15·5°/15·5° and using the divisor 4·00 to calculate grms. of extract per 100 c.c. These values can be calculated in terms of per cent. by weight by means of the expression

$$p = \frac{x}{0{\cdot}999056.d}$$ where p = percentage by weight, x = grms. per 100 c.c.; d = sp. gr. of wort at 15·5°/15·5° and 0·999056 = density of water at that temperature. Mohr, on the other hand, deprecates the inconvenience involved in accepting the English temperature of 15·5° C., and in using two divisors, and advocates the general use of Windisch's tables, in spite of the fact that the results are too high for saccharified liquids. He contends that the composition of wort is so complex and variable that no divisor could possibly give anything but relative values.—J.F.B.

Beer analysis with the refractometer. E. Ackermann and F. Toggenburg. Z. ges. Brauw., 1906, **29**, 145—147.

THE determination of alcohol and extract in beer can be made by observing the refractometer values of the beer and the alcoholic distillate in a Zeiss immersion refractometer, and calculating the results by means of the Ackermann slide-rule (see also this J., 1905, 563 and 630). Experience has shown that although the method is, on the whole, extremely accurate, some little difficulty is met with in obtaining reliable readings in the case of dark beers. In such cases it is now recommended that the refractometer value should be observed as nearly as possible, and that a colourless solution of sugar of approximately the same refractometer value as the beer should then be prepared and observed in the instrument, which should then be adjusted so that the colourless line of separation on the scale is accurately visible. Lastly, the beer should again be examined in the instrument thus adjusted, the error due to colour being thereby reduced to a minimum. When a series of observations is made it often happens that the first two or three readings give incorrect results; this is due to the fact that the prism of the refractometer has not had time to attain the correct temperature of 17·5° C., at which the liquids are examined. The extract is calculated by the formula $E = [1 - I^1] \times 6750$, where I = the refractive index of the original beer, and I^1 = that of the alcoholic distillate. With the Zeiss immersion refractometer it is more convenient to calculate direct from the refractometer scale-values observed, R and R^1 respectively; the expression then becomes: $E = [R - R^1] \times 0{\cdot}25705$. The method is regarded as being more rapid and quite as accurate as the specific gravity method. —J. F. B.

Carbonyl group in aldehydes, ketones, &c.; Quantitative determination of the ——. Watson Smith, jun. Chem. News, 1906, **93**, 83—84.

THE author has devised certain modifications of Strache's method of estimating carbonyl groups. Strache (Monatsh. f. Chem., **12**, 514; **13**, 299), and Benedikt and Strache (Monatsh. f. Chem., **14**, 279; this J., 1893, 185, 1066), mix the aldehyde or ketone with excess of phenylhydrazine,

gunpowder in the proportion of 7—8 per cent. of the whole mass, which is mixed with 5—15 per cent. of water, then subjected to sufficient heat to swell the starch granules, and pressed into the required shape.—B. J. S.

FRENCH PATENT.

Nitroglycerin; Manufacture of ——. The Eastern Dynamite Co. Fr. Pat. 358,514, Oct. 14, 1905.

SEE U.S. Pat. 804,817 of 1905; this J., 1906, 199.—T.F.B.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 238.)

APPARATUS, ETC.

UNITED STATES PATENT.

Gases; Apparatus for analysis of ——. A. Schlatter and L. Deutsch, Budapest, Austria-Hungary. U.S. Pat. 813,671, Feb. 27, 1906.

SEE Fr. Pat. 351,442 of 1905; this J., 1905, 904.—T. F. B.

INORGANIC—QUALITATIVE.

Schlagdenhaufen's reaction [for magnesium]; Modification of ——. L. Grimbert. J. Pharm. Chim., 1906, **23**, 237—239.

SCHLAGDENHAUFEN'S reaction for magnesium is best modified as follows:—To 10 c.c. of the liquid to be examined, 5 c.c. of 10 per cent. potassium iodide solution are added, followed by two or three drops of a strong solution of sodium hypochlorite. In the presence of magnesium, a reddish-brown flocculent precipitate will be formed, resembling ferric hydroxide in appearance. The reaction is very distinct with a dilution of 1:2000. It is essential that the solutions should be neutral, or but faintly alkaline; the least trace of free acid prevents the formation of the precipitate; an excess of alkali also renders the reaction less sensitive. Neither colour nor precipitate is given by lithium, nor by salts of the earthy metals.—J. O. B.

Arsenic from hydrochloric acid; Removal of ——, *for use in the Marsh-Berzelius method.* A. R. Ling and T. Rendle. Analyst, 1906, **31**, 37—38.

THE method described consists in boiling a mixture of hydrochloric acid of constant boiling point, and methyl alcohol in a reflux apparatus under reduced pressure with bright electrolytic copper free from arsenic, and then distilling the acid over similar copper. To 1,500 c.c. of commercial hydrochloric acid of a sp. gr. slightly above 1·1, about 40 c.c. of redistilled commercial wood-spirit are added, the mixture being contained in a Würtz flask of 2 litres capacity. About 5 grms. of arsenic-free granulated zinc are then added and the flask is connected with a reflux condenser by an ordinary cork, in which is fixed a glass rod supporting a coil of electrolytic copper foil, having a surface of about 120 sq. ins. The side tube of the flask having been plugged, the condenser is connected with an exhaust-pump, and the boiling commenced and continued for some hours, the copper being withdrawn and cleaned at least once during this period. It is advisable to interpose two vessels between the condenser and the pump. The first serves to collect a black tarry liquid which distils over, whilst the second flask contains a little water to absorb any hydrogen chloride which passes off. The acid is then distilled in presence of bright electrolytic copper.—W. P. S.

INORGANIC—QUANTITATIVE.

Pyrites; Determination of sulphur in ——. F. Raschig. Z. angew. Chem., 1906, **19**, 331—334.

THE author considers the benzidine method quite as accurate as the barium method, if not more so, provided due care be taken. He gives the following detailed directions for carrying out the process:—Exactly 0·8 grm. of the finely-powdered sample is weighed into a dry 200 c.c. conical flask, 5 c.c. of fuming nitric acid are added, and the flask heated on the water-bath with a small funnel in the neck. After half an hour 30 c.c. of water are added, and the whole contents are rinsed into a 100 c.c. flask, made up to the mark, and well shaken. Then 20 c.c. are placed in a 600 c.c. beaker, 10 c.c. of a 1 per cent. solution of hydroxylamine hydrochloride are added, and 500 c.c. of benzidine solution (this J., 1903, 1066). The liquid is well stirred and allowed to stand for 15 minutes, during which time the filter is prepared as directed, *loc. cit.* The bulk of the clear liquid is poured through the filter, and the precipitate brought on by about the last fifth of it, the last portions being rinsed on by means of some of the filtrate, or by benzidine solution from a wash-bottle. Water may be used, if not more than 10—20 c.c. be taken, and the washings be brought into the filter while still nearly full of liquid. The moment the water disappears from the surface of the precipitate the funnel is washed down with 5—10 c.c. of water, and this is followed by a second like quantity. As soon as this has disappeared, the pump is disconnected, so that the precipitate does not get felted together. The funnel is now removed, inclined at 45°, and the filter and plate overturned in the funnel by a rod pushed up from below. The plate is removed, the filter pressed together in the fingers, and dropped into a 250 c.c. conical flask with a neck 30 mm. wide, into which any precipitate adhering to the funnel is rinsed with not more than 25 c.c. of water. The flask is corked, the contents violently shaken till the precipitate is thoroughly broken up, the cork rinsed into the flask, nearly the requisite quantity of N/10 sodium hydroxide added (in this case, say, 40 c.c.), then about 2 c.c. of the usual phenolphthalein solution (this amount is needed because so much is absorbed by the filter paper). The flask is now heated till the red colour disappears, and then the titration proceeded with till the red colour is permanent on boiling. It should be destroyed by addition of a drop or two of N/10 hydrochloric acid, and not return on boiling for two minutes. The filtrate must always be tested with barium chloride, to make sure that enough benzidine solution has been used for complete precipitation. The method requires some practice, but the author states that when once expertness has been acquired in carrying it out, it will always be preferred to the barium method.—J. T. D.

Sulphates; Determination of —— *in drinking waters.* F. Raschig. Z. angew. Chem., 1906, **19**, 334.

To a quantity—½ to 5 litres—of the water is added one-twentieth of its volume of *strong* (this J., 1903, 1066) benzidine solution, and after 15 minutes the precipitate is filtered off and titrated as described in the method for pyrites (see preceding abstract). To the result, when expressed in milligrammes of sulphur trioxide per litre, 1·5 mgrms. are added, for the solubility of benzidine sulphate in the liquid. Should the water contain iron, 1—2 c.c. of hydroxylamine hydrochloride (1 per cent. solution) are added before precipitation.—J. T. D.

Metals, especially gold and palladium; Determination of —— *by electric conductivity measurements.* J. Donau. Monatsh. f. Chem., 1906, **27**, 59—70.

THE solution of the metal, very slightly acidified with hydrochloric acid, is placed in a U-tube constricted at the bend and furnished with a side-tube for the entry of carbon monoxide, and its conductivity is measured. Pure carbon monoxide is then led through, and the conductivity measured from time to time till it ceases to increase. The increase in conductivity is in the case of palladium directly proportional to the amount present; in the case of gold it is not so, but the connection between the two can be expressed by the formula:

$Z = 1{\cdot}76x - 0{\cdot}0237xy + 0{\cdot}0138x^2 - 0{\cdot}00111x^2y + 0{\cdot}000738xy^2$,

where Z = mgrms. of gold in 100 c.c. of the solution, and y and x are the original conductivity and increase in conductivity, respectively, expressed in the usual Kohlrausch units multiplied by 10^6.—J. T. D.

THIS, the concluding number of Lehne's work, contains 48 pages or specimen-sheets (dyed and printed patterns), giving the Trade names of the Dyestuffs used in one column and the mode of employment, fastness, and method of detection on the fibre in the second column, and in the third column the specimen itself. In the second column is also given the number in Schultz's Tables in which the same dyestuff is referred to. (See also this J., 1905, 296.) The dyestuffs illustrated in this third part are as follows:—III. Triphenylmethane and Diphenylnaphthylmethane dyestuffs (cont.). IV. Pyronine dyestuffs. V. Acridine dyestuffs. VI. Oxyketone and allied dyestuffs. VII. Oxazine dyestuffs. VIII. Azine dyestuffs. IX. Thiobenzenyl dyestuffs. X. Indigo group. XI. Sulphide dyestuffs. XII. Dyestuffs of unknown constitution. At the end of this concluding part is an alphabetical index of the dyestuffs illustrated.

PRACTICAL EXERCISES IN CHEMISTRY. By G. C. DONINGTON, M.A., Senior Science Master of Leeds Grammar School. Macmillan and Co., Ltd., London. 1906. Price 2s. 6d. The Macmillan Co., New York.

12MO. volume containing 245 pages of subject matter, with 83 illustrations, and the alphabetical index, and taking the form of a text-book for the inculcation of a scientific method of chemical and physical observation and experiment.

NEW CUSTOMS TARIFF OF ROUMANIA AS MODIFIED BY COMMERCIAL TREATIES WITH THE UNITED KINGDOM AND GERMANY, WITH A SUMMARY OF THE NEW LAW RELATING TO TARE ON GOODS DUTIABLE BY WEIGHT. Wyman and Sons, Fetter Lane, E.C. [Cd. 2828.] Price 7d.

[A.] 7535. Redfern (Basle Chemical Works). Manufacture of monazo dyestuffs. March 28.
[C.S.] 12,444 (1905). Johnson (Badische Anilin und Soda Fabrik). Reduction of indigo and similar colouring matters. April 4.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 6544. Jeschke. Process for contemporary dyeing, glueing and drying of coloured textile bast-ribbons. March 19.
„ 6654. Wilson. Machines for printing textile fabrics. March 20.
„ 6848. Wood, Bowden and Unwin. Calico printing machines. March 22.
„ 6932. Ingham. Manufacture of sizing, thickening, stiffening or waterproofing material for fabrics. March 22.
„ 6992. Beresin. Treatment of cotton yarns and fabrics to improve their texture and render their dye more permanent. March 23.
„ 7520. Verein. Kunstseidefabr. A.-G. Manufacture of artificial hemp-bast and the like. [Ger. Appl., Jan. 2, 1906.]* March 28.
„ 7617. Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging pastes for use in the discharge of dyed textile fibres.* March 29.
„ 7657. Dreaper. Manufacture of artificial silk and the like. March 30.
[C.S.] 6160 (1905). Muntadas y Rovira. Winding fabrics in continuous bleaching apparatus. April 4.
„ 6645 (1905). Armitage. Finishing of certain fabrics. April 4.
„ 10,691 (1905). Burt, Jackson and Finch. Extraction of grease from wool and apparatus therefor. March 28.
„ 12,545 (1905). Shuttleworth and Shuttleworth. Apparatus for washing textile fabrics. April 4.
„ 14,480 (1905). Nitritfabrik G.m.b.H. Process for mordanting wool. March 28.
„ 15,518 (1905). Pomortzeff. Treatment of tissues, fabrics and paper for increasing their durability and rendering them waterproof. March 28.
„ 50 (1906). Marshall. Washing machines. April 4.
„ 92 (1906). Villam. Machines for gassing yarns and threads. April 4.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 6529. Spence, and Spence and Sons, Ltd. *See under* I.
„ 6643. Wilson. Utilisation of alkali or tank waste, or other waste products produced by alkali manufacturers. March 20.
„ 6711. Van der Sleen. Ozone generators.* March 20.
„ 7007. Hunt (Love). Lixiviation apparatus, especially for the extraction of sodium nitrate from caliche.* March 23.
„ 7297. Lance and Elworthy. *See under* XX.
„ 7395. Dollschaft. *See under* I.
„ 7478. Fairweather (Beaver and de Nordenflycht). Dissolving plant for the recovery of sodium nitrate from caliche.* March 28.
[C.S.] 26,384 (1905). Bloxam (Gebr. Siemens und Co.). Manufacture of solid forms with the aid of silicon. March 28.
„ 26,788 (1905). Potter. Manufacture of silicon monoxide. March 28.
„ 26,899 (1905). Browne. *See under* II.
„ 2708 (1906). Tcherniac. Manufacture of sulphocyanides. March 28.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 6533. Hancock. Decoration of pottery ware. March 19.
[C.S.] 2879 (1906). Chambers. Apparatus for drawing glass. April 4.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 6946. Morgan. Cement kilns.* March 22.
„ 7316. Oddy. Manufacture of artificial building blocks. March 27.
„ 7443. Zulkowski. Manufacture of Portland cement. March 28.
„ 7464. Price. Utilising surplus heat of brick kilns.* March 28.
„ 7629. Müller. Manufacture of a moulding powder.* March 29.
[C.S.] 19,686 (1905). Freakley and Bill. Manufacture of materials for the construction of dustless roads and like surfaces. April 4.
„ 21,141 (1905). Wickre. Building blocks. April 4.

X.—METALLURGY.

[A.] 17,370A (1905). Leggo. Furnaces for treating ores and other substances.* March 30.
„ 6569. Townsend. Reduction of sulphide ores or compounds.* March 19.
„ 6937. Holland. Recovery of metals from liquids.* March 22.
„ 6955. Cowper-Coles. Rendering silver untarnishable. March 23.
„ 7146. Sulman. Ore concentration. March 24.
„ 7178. Weekley. Treatment of slimes and cognate material. March 24.
„ 7195. Rolason. Silver alloys.* March 26.
„ 7203. Cowper-Coles. Rendering silver untarnishable. March 26.
„ 7274. Hopkins. Condensation and separation of zinc vapours from other gases or vapours. March 26.
„ 7541. Howatt. Mineral washing and separating apparatus.* March 28.
„ 7546. Cowper-Coles. Rendering silver non-tarnishable. March 29.
„ 7650. Blake. Manufacture of metals. March 30.
„ 7655. Kuzel. Increasing the electrical resistance of metals. [Ger. Appl., July 26, 1905.]* March 30.
„ 7660. Bailey and Lovatt. Case hardening composition. March 30.
„ 7757. Tatlock. Production of a protective coating upon iron and steel. March 31.
„ 7770. Edwards. Concentrator for separating minerals and metals from crushed ores. March 31.
[C.S.] 5970 (1905). Thompson (Merrill). Filter presses for separating the components of the tailings of ores and other material. March 28.
„ 6556A (1905). Hutchings. Disintegrating and mixing pans used in ore dressing. March 28.
„ 6556B and C (1905). Hutchings. Washing, separating and concentrating precious matters from deposits or tailings from ore crushing. March 28.
„ 13,018 (1905). Shaw. Apparatus for washing coal and other minerals. April 4.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 11,654A (1905). Schanschieff. Accumulator plates.* March 31.
„ 6976. Bingham. Electric furnaces. March 23.
„ 6977. Bingham. Electric furnaces. March 23.
„ 6978. Gibbs. Production of articles by electro-deposition. March 23.
„ 6980. Gibbs. Manufacture of metal articles by electro-deposition. March 23.
„ 7340. Bingham. Electric furnaces. March 27.
„ 7457. Langton and Langton. Electric accumulator. March 28.
„ 7597 and 7598. Allmänna Svenska Elektriska Aktiebolag. Electrically-heated shaft furnaces. [Swed. Appl., March 30, 1905.]* March 29.

[A.] 7829. Thompson (Westdeutsche Thomasphosphatwerke). Process for causing endothermic reactions in gases by aid of electric discharges. March 31.
[C.S.] 6448 (1905). Bastian and Calvert. Substances for effecting catalytic combinations in electrolytic electricity meters. April 4.
„ 6786 (1905). Gerard and Fiedler. Plates for accumulators. April 4.
„ 7004 (1905). Reynolds. Electric furnaces. April 4.
„ 22,103 (1905). Gaiffe. Ozonising apparatus. March 28.
„ 1925 (1906). Edison. Storage battery electrode. March 28.
„ 1927 (1906). Edison. Electrode mass for storage batteries. April 4.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 6601. Blass. Process for solidifying fluid greases, tar, &c., and increasing the consistency of solid fats, resins, soaps, or the like.* March 19.
„ 6712. Jackson. Detergent. March 20.
„ 6923. Cramp. *See under* XIII*B*.
„ 7380. Samul. Manufacture of soaps, detergents, lubricants, batching, candle stock, &c. March 27.
[C.S.] 4092A (1905). Krebitz. Process for converting an insoluble soap into soluble soda soap or potash soap. April 4.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(*A.*)—PIGMENTS, PAINTS.

[A.] 7073. Clark (Standard Paint Co., Inc.). Manufacture of paint.* March 23.
„ 7819. Ephraim. Process for rendering lithopone more stable against light. [Ger. Appl., April 1, 1905.]* March 31.
[C.S.] 5872 (1905). Dreyfus. Paint. March 28.

(*B.*)—RESINS, VARNISHES.

[A.] 6601. Blass. *See under* XII.
„ 6923. Cramp. Treatment of vegetable and animal oils to thicken or dry them, especially for the manufacture of linoleum. March 22.
„ 7036. Kent. Declorising and deodorising Russian turpentine. March 23.

(*C.*)—INDIA-RUBBER.

[A.] 7064. Welch, and Harvey, Frost and Co., Ltd., Vulcanising. March 23.
[C.S.] 2247 (1906). Wilkinson, Gubbins and Quin. Apparatus for separating the component parts of rubber waste. March 28.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 7010. Lobb. Treatment of leather.* March 23.
[C.S.] 16,312 (1905). Riviere, Verroul and Bouvier. Tanning hides or skins. March 28.

XVI.—SUGAR, STARCH, GUM, ETC.

(A.) 6529. Spence, and Spence and Sons, Ltd. *See under* I.
„ 7046. Scott. Manufacture of sugar. March 23.
„ 7705. Drittler. Improved starch and process of producing the same.* March 30.

XVII.—BREWING, WINES, SPIRITS, ETC.

[A.] 6640. Ehrlich. Process for making fusel oil and components of fusel oil. [Ger. Appl., March 31, 1905.]* March 20.
„ 6770. Hilliard. Treatment of whisky for the removal of the noxious elements from the higher alcohols.* March 21.
[A.] 7679. Carroll. Apparatus for distilling and treating spirits. March 30.
„ 7702. Faulkner. Apparatus for producing malt extract or wort. March 30.
„ 7830. Hunt. Improving, maturing or ageing whisky and other spirits. March 31.
[C.S.] 11,453 (1905). Hahn and Reiser. Production of dry yeast. April 4.
„ 1639 (1906). Effront. Process of preparing malt by means of chloride of lime or other hypochlorite salts. April 4.

XVIII. FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(*A.*)—FOODS.

[A.] 7329. Williams. Preparation of leguminous proteins from ground-nuts and similar seeds. March 27.

(*B.*)—SANITATION; WATER PURIFICATION.

[A.] 6806. Rubert and Laporta. Composition for removing and preventing incrustation in water receptacles. [Appl. in Spain, Dec. 9, 1905.]* March 21.
[C.S.] 15,872 (1905). Wollaston. Apparatus for softening and purifying water. March 28.
„ 1158 (1906). Schmidt. Purifying apparatus for liquids. April 4.

(*C.*)—DISINFECTANTS.

[A.] 6676. Smith and Davis. Disinfectants and deodorisers. March 20.
„ 7487. Newton (Bayer und Co.). *See under* XX.

XIX.—PAPER, PASTEBOARD, ETC.

(A.) 6590. Fritsch. Process for rendering paper moisture-proof and durable.* March 19.
„ 6851. Mastin. Treatment of cardboard, millboard, pulp, sawdust, fibre and the like. March 22.
„ 6942. Bosch, Bosch and Müller. Direct production of coloured cellulose articles. [Ger. Appl., April 1, 1905.]* March 22.
[C.S.] 14,789 (1905). Dobler. Sizing paper or card. March 28.
„ 15,518 (1905). Pomortzeff. *See under* V.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 6606. Johnson (Badische Anilin und Soda Fabrik). Production of borneol esters and isoborneol esters.* March 19.
„ 7018. Annison and Oliver. Extraction of a liquid extract of locust beans, and apparatus therefor. March 23.
„ 7125. Wellcome, Jowett and Pyman. Manufacture of a new salicylic acid derivative. March 24.
„ 7297. Lance and Elworthy. Manufacture of formaldehyde, formic acid, methyl alcohol and their derivatives. [Fr. Appl., March 24, 1905.]* March 26.
„ 7487. Newton (Bayer und Co.). Generation of gaseous formaldehyde. March 28.
[C.S.] 15,456 (1905). Zimmermann (Chem. Fabr. auf Actien, vorm. E. Schering). Manufacture of ω-alkylaminoethylbenzoates. March 28.

XXII.—EXPLOSIVES, MATCHES, ETC.

[A.] 6581. Nathan, Thomson, Rintoul and Scott. Manufacture of nitroglycerine. March 19.
„ 6705. Venier. Explosive composition.* March 20.
„ 6824. Weizmann, Dreyfus, and the Clayton Aniline Co., Ltd. Manufacture of explosives. March 21.

Official Notices.

EXTRAORDINARY GENERAL MEETING OF THE SOCIETY.

An Extraordinary General Meeting of the Society was held at 3.30 o'clock, in the afternoon of Tuesday, the twenty-seventh day of March, 1906, at the House of the Society of Arts, by kind permission of the Council of that Society, with the object of considering and adopting the resolution mentioned in the Requisition hereinafter set forth:—

"TO THE PRESIDENT AND COUNCIL OF THE SOCIETY OF CHEMICAL INDUSTRY."

We, the undersigned Members of the Society of Chemical Industry, hereby request that, in accordance with Bye-Law 40, you will convene an Extraordinary General Meeting of the Society with the object of considering, and if approved by the said Extraordinary Meeting, of adopting the following resolution (that is to say):—

RESOLUTION.

"That it is desirable that the Society of Chemical Industry as now existing should be incorporated under and subject to the grant of a Royal Charter and that the Council be and hereby is authorised to take all necessary steps to procure the grant of a Royal Charter of Incorporation."

Dated this twenty-second day of December, 1905.

Here follow signatures of the following:—

Dr. Leo Backeland.	Henry de Mosenthal.
George Beilby.	Prof. Chas. E. Munroe.
V. G. Bloede.	Jas. P. Murray.
Jas. H. Bowman.	Robert W. Neff.
Eugene A. Byrnes.	Dr. Wm. H. Nichols.
Eustace Carey.	Thos. J. Parker.
Prof. Charles F. Chandler.	A. L. Norton.
Prof. Frank Clowes.	D. H. T Peploe.
Frederick P. Dewey.	Dr. W. H. Perkin.
Dr. Edward Divers.	Dr. Frederick B. Power.
Dr. A. R. L. Dohme.	Sir William Ramsay.
Thos. Fairley.	Sir Boverton Redwood.
Dr. Fred. W. Frerichs	Walter F. Reid.
Oscar Guttmann.	President Ira Remsen.
Samuel Hall.	Sir Henry E. Roscoe.
Jas. Otis Handy.	George D. Rosengarten.
Dr. B. J. Harrington.	Dr. Samuel P. Sadtler.
Dr. Edward Hart.	Alfred Gordon Salamon.
Otto Hehner.	Dr. Hugo Schweitzer.
E. Grant Hooper.	Dr. Karl F. Stahl.
David Howard.	H. E. Stuart.
H. August Huneke.	Sir Joseph W. Swan.
C. C. Hutchinson.	Prof. H. P. Talbot.
Prof. Edward H. Keiser.	M. J. Taylor.
Prof. W. R. Lang.	E. C. Thompson.
Ivan Levinstein.	Dr. T. E. Thorpe.
Arthur R. Ling.	Prof. W. A. Tilden.
Dr. E. G. Love.	Thos. Tyrer.
Anthony McGill.	John H. Usmar.
Edward Mallinckrodt.	W. H. Van Winckel.
N. H. Martin.	S. S. Voorhees.
Prof. R. Meldola.	Dr. W. H. Walker.
Dr. Rudolph Messel.	R. A. Wallace.
Dr. W. Lash Miller.	Charles Wightman.
Dr. Ludwig Mond.	Dr. H. W. Wiley.
Dr. Russell W. Moore.	Reginald C. Woodcock.

The President, Dr. Edw. Divers, F.R.S., occupied the chair. The Secretary having read the notice of meeting, on the motion of Sir Boverton Redwood, seconded by Mr. A. Gordon Salamon, the above resolution was unanimously adopted. A full account of the proceedings is in preparation.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906.

The attention of Members is drawn to the Notice which accompanied the February 15th issue of the Journal.

LIST OF DELEGATES.

Board of Education.—Prof. Wm. A. Tilden, F.R.S.

Department of Agriculture and Technical Instruction, Ireland:—Prof. Walter N. Hartley, F.R.S.

Royal Society.—Prof. R. Meldola, F.R.S.; Dr. L. Mond, F.R.S.; Prof. W. A. Tilden, D.Sc., F.R.S.

Chemical Society:—Prof. W. R. Dunstan, LL.D., F.R.S.; Prof. R. Meldola, F.R.S.; Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.; Prof. W. A. Tilden, D.Sc., F.R.S.

Society of Chemical Industry:—Prof. Edward Divers, M.D., D.Sc., F.R.S.; George Beilby, F.R.S.; Oscar Guttmann; Prof. W. R. Hodgkinson; E. Grant Hooper; Dr. J. Lewkowitsch, Dr. K. E. Markel; Dr. L. Mond, F.R.S.; Sir William Ramsay, K.C.B., LL.D., F.R.S.; Sir Boverton Redwood; Walter F. Reid; Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.; Sir Henry E. Roscoe, LL.D., F.R.S.; Dr. W. S. Squire.

Iron and Steel Institute:—J. E. Stead, F.R.S.; Bennett H. Brough.

Royal Photographic Society:—Major Gen. J. Waterhouse; Prof. R. Meldola, F.R.S.

British Association for the Advancement of Science:—Prof. R. Meldola, F.R.S.

Faraday Society:—Dr. H. Borns; J. B. C. Kershaw.

Royal Society of Edinburgh:—Dr. James J. Dobbie, F.R.S.

Federated Institute of Brewing:—Dr. L. T. Thorne.

Institution of Mining and Metallurgy:—Prof. H. Bauerman; Bedford McNeill.

Society of Dyers and Colourists:—Sir Thomas Wardle.

Society of Arts:—Sir Boverton Redwood.

LIST OF PAPERS.

Three communications will be read before the full Congress, viz., "The Purification of Sewage," by Sir William Ramsay; "The Distillation of Metals," by Henri Moissan; "The Direct Utilisation of Atmospheric Nitrogen in the Production of Manures and Chemical Products," by A. Frank.

The following are the titles of the more important papers to be read before the various sections:—

SECTION I.—(Analytical Chemistry—Apparatus and instruments.)

"Rapport général sur les travaux de la Commission Internationale d'Analyse," by Prof. G. Lunge, of Zürich.

"Sur les caractères chimiques, physiques et commerciales des soies pures á l'état grège, mouliné et teint," by Prof. Gianoli, of Milan.

"Sur l'état actuel de la chimie analytique du caoutchouc, des objets de caoutchouc et des derivés," by Dr. E. Marckwald, of Berlin.

"Essai industriel du carborundum amorphe," by Prof. G. Chesnau.

"Détermination de l'azote dans les mélanges gazeux," by Dr. H. P. Ladoff, of Crakow.

"Séparation du fer d'avec les autres metaux et d'avec les métalloides," by Cap. Nicolardot, of Paris.

SECTION II.—(Inorganic chemistry and allied industries.)

"Sur l'industrie des engrais chimiques et du sulfate de cuivre en Italie," by Profs. Menozzi and Gianoli, of Milan.

"L'industrie de l'acide borique en Italie," by Prof. R. Nasini, of Padova.

"Acide sulfurique," by Dr. W. S. Squire, of London.

"Fused sodium peroxide and its use in air purification," by Dr. H. Philipp and R. v. Forreger, of New York.

"Ueber neuere Stickstoffquellen," by N. Caro, Berlin.

"Industrie chimique dans la Republique Argentine," by F. P. Lavalle, Paris.

SECTION III.—(Metallurgy and Mines—Explosives.)

"Le progrès de la siderurgie en Italie et particulièrement au regard des hauts-fourneaux," by Dr. U. Monsacchi, of Piombino.

"Progrès de la metallurgie du cuivre," by Jannettaz, Paris.

"Rapport sur l'état actuel de la metallurgie du fer en France," by the "Comité des forges de France."

"Die Fortschritte in der Flusseisenerzeugung," by Prof. H. Wedding, Berlin.

"Nouveaux mélanges détonantes pour charger des capsules ou des autres appareils déterminants l'explosion ou la détonation," by Dr. U. Alvisi, Caltanisetta.

"Méthode pour déterminer le brisant aux matières explosives," by A. Werner Cronquist, Stockholm.

"Ungefrierbare Nitroglycerin Sprengstoffe," by W. A. Roewer, Hamburg.

"Sprengungen unter Wasser, deren Messung und Registrirung zu halten," by Dr. H. Mettegang, Schlebusch.

SECTION IV.—(Organic Chemistry and allied industries.)

"Sur l'industrie des matières grasses en Italie," by Prof. Gianoli, Milan.

"Sur l'utilisation de l'azote de l'atmosphère au moyen du calcium et du baryum," by Dr. Piccinni, Pont St. Martin.

"Sur la soie artificielle," by Dr. E. Molinari, Milan.

"Comparison of the characters of petroleums of recent development with that of the older sources of supply," by Clifford Richardson, New York.

"Ueber die künstliche Darstellung des Camphers," by Dr. A. Hesse, Berlin.

"Die Verunreinigungen des Calciumcarbids und selbstentzündungen des Acetylens," by N. Caro, Berlin.

"Nouveaux procedés pour la fabrication du gaz d'éclairage," by Prof. P. Sabatier, Toulouse.

"Actions chimiques de la lumière," by Prof. G. Ciamician and P. Silber, of Bologna.

"Sur l'état de l'industrie tenturière en Italie," by Dr. L. Caberti and G. Taghani, of Milan.

"Formation de nouveaux colorants dans les tissus moyennant le formaldéhyde," by Dr. R. Lepetit, Garessio.

"The systematic study of absorption spectra as applied to determining problems of chemical constitution in colourless and coloured substances," by Prof. W. N. Hartley, of Dublin.

"On the chemistry of the lakes employed in dyeing," by Dr. P. D. Zacharias, Athens.

"Sur les couleurs rencontrées dans les ruines de Pompeii," by Max Meyer and P. Bonomi, of Milan.

SECTION V.—(Industry and chemistry of sugar.)

"Sur le développement de l'industrie sucrière en Italie," by Hon. Deputé Maraini, of Rome.

"Ueber die neuesten Fortschritte in der Saftgewinnung aus Rüben," by Dr. H. Claassen, Dormagen.

"Fabrication du sucre de lait par l'électrolyse," by F. Dupont, Paris.

"The effect of environment upon the composition of sugar-producing plants," by Prof. H. W. Wiley, Washington.

"The fight between cane and beet sugar," by Sigmund Stein, Liverpool.

"The chemical selection of the cane," by Dr. Kobus, Pekalongan (Java).

"Etude comparative des analyses des produits sucres," by Prof. V. Villavecchia and Dr. G. Rossi, of Rome.

"Sur le phénomene de la caramelisation," by A. Trillat, Paris.

"Dry lead defecation in optical sugar analysis," by Dr. W. D. Horne, New York.

"Le dessiccation des pulpes de betteraves et de la bagasse de la canne à sucre," by A. Huillard, Suresnes (Paris).

SECTION VI.—(Fermentation and starches.)

"Resultats obtenus à l'ancienne Station de meunerie à Berlin, surtout sur la panification," by Prof. L. Wittmack de Berlin.

"Nouvelle méthode pour déterminer la valeur des farines dans la panification," by Dr. F. Tusini, of Modena.

"Fermentation," by Dr. W. S. Squire, of London.

"What are the most suitable means for retarding the fermentation of must in hot climates to secure wines of better bouquet?" by Prof. P. D. Hah, of Cape Town.

"Eine zwanzigjährige Erfahrung in der fabrikmässiger Herstellung von Reinhefe," by Dr. H. Helm, La Haye.

"Sur la necessité d'un méthode uniforme pour la determination de l'extrait sec des mouts et matières saccharines utilisées en brasserie," by H. van Laer, Bruxelles.

SECTION VII.—(Agricultural Chemistry.)

"Analyses of Effluents of Septic Tanks for Sewage Disposal in India: A description of the Indian Government's Agricultural Chemical Research Laboratories now under construction at Pusa," by Dr. J. W. Leather, Bombay.

"Important problems of Agricultural Chemistry in the United States," by Prof. H. W. Wiley, of Washington.

"Ueber die chemischen Vorgänge bei der assimilation des elementares Stickstoffes durch Azotobakter und Radiobakter," by Dr. J. Stoklasa, Prag.

"Sur la dialyse des sols," by Dr. Ch. Garola, Chartres.

"Sur le camphre italien," by Prof. J. Giglioli, Pisa.

"Recherches et applications bacteriologiques au point de vue de la fabrication du fromage," by Prof. G. Gorini, Milano.

"Der derzeitige Stand und die Bedeutung der bacteriellen Bodenuntersuchung," by Prof. Remy, Bonn.

"Sur la recherche de l'arsenic dans l'ail," by Prof. S. Minorci, Bukarest.

"Les eaux de la région du Lac Manont pour l'irrigation du Désert," by Prof. H. D. Parodi, Cairo.

"Analyses des terres dans les régions tropicales ou subtropicales," by V. Mosséri, Cairo.

SECTION VIII.—(Hygiene, Medicinal and pharmaceutical Chemistry, bromatology.)

"Sur la constitution chimique du cerveau," by Prof. Albertoni, Bologna.

"Sur les composés du foie qui contiennent du fer," by Prof. L. Beccari, Bologna.

"Révélateurs biochimiques des microbes," by Prof. B. Gotio, Rome.

"Sur la récherche chimique légale des médicaments nouveaux," by Dr. T. Panzer, Wien.

"The toxic principle in the bitter variety of Luffa aegyptiaca," by Dr. C. L. Bose, Calcutta.

"Contribution à l'étude des matières albuminoides de l'urine et du sérum du sang," by Dr. G. Patein, Paris.

"Die Refraktometrie im Dienste der Pharmazie," by Dr. E. Riegler, Jassy.

"Rapport sur les travaux de la commission internationale d'unification des méthodes d'analyse des denrées alimentaires," by J. B. André, Bruxelles.

"The inspection of food products imported into the United States." "The use of sulphur fumes in the preparation of food products," by Dr. H. W. Wiley, of Washington.

"Pflanzenfette als Ersatzmittel der Butter und Margarine," by H. Thoms, Berlin.

"Ist eine Begrenzung der Nebenbestandtheile (sogenannten Verunreinigungen) in natürlichem Branntwein empfehlenswerth?" by Dr. Hugo Mastbaum, of Lisbon.

SECTION IX.—(Photochemistry; photography.)

"The application of photography to the solution of problems in Chemistry," by Prof. W. N. Hartley, of Dublin.

"Sur une nouvelle méthode de photographie des couleurs." "Sur une nouvelle méthode photographique permettant d'obtenir des préparations sensibles noircissant directement à la lumière et ne contenant pas des sels d'argent solubles," by A. Lumière, Lyon.

"Observations et remarques sur les travaux photographiques en couleurs naturelles," by S. De Prokondine-Gorsky, St. Petersburg.

SECTION X.—(Electro-chemistry; physical chemistry.)

"The most recent methods for the electrolytic refining of copper," by S. Cowper-Coles, of London.

MR. EUSTACE CAREY IN THE CHAIR.

VANADIUM AS A STEEL MAKING ELEMENT.

J. KENT SMITH.

The element vanadium until quite recently could only be considered academically, but its industrial importance in the steel trade, due to its power of imparting properties to steel which are not otherwise obtainable, is now becoming very considerable, and I therefore venture to hope that a brief *resume* of the properties of some commercial vanadium steels made by the open-hearth process may not be without interest to this Society.

Vanadium is said to be one of the "rare" elements, but it is perhaps necessary to take this description as being accurate only in a sense. As a matter of fact, vanadium in minute proportions is very widely distributed, though in such quantity or states of combination as render its extraction on a commercial scale quite out of the question.

It is not my intention to deal with the history of the metal, nor with the processes used for its extraction and reduction from the various ores adapted to this purpose, as the matter has already been dealt with at some length before this Society. Rather is it my desire to confine my remarks to some products of its application as far as steel manufacture is concerned. It will, therefore, be sufficient if, in supplement to the information given by H. P. Smith (this J., 1901, 1183), it is said that although metallic vanadium itself has a very high m. pt., an alloy of iron containing 30—40 per cent. of vanadium has a m. pt. nearly 150° C. below that of mild steel, so that by its judicious use, vanadium can be, and is being regularly, introduced into steel with ease and without undue loss.

Several years ago my attention was directed to some effects of vanadium upon a sample of steel, and it became my wish to investigate such effects as completely as possible. Some work in this direction had already been done, but the records were, in many instances, somewhat vague, and in many others apparently contradictory. In the light of present knowledge this apparent contradiction is susceptible of possible explanation in at least two directions. Firstly, the analytical determination of vanadium was none too simple at that time, and its correct estimation required the exercise of much skill and a prolonged elaboration of detail. I have said that vanadium can be alloyed with steel without undue loss, but it is by no means a corollary that the addition of a certain proportion of vanadium to steel necessarily points to the fact of that steel containing that proportion. It is then but fair to assume that figures then available would not, in some cases, be reliable indications of the effect of a specified *content* of vanadium, but rather records of the results following the *addition* of that quantity of vanadium. Again, it has been abundantly shown that, at the recalescence point, Ac1, a great rearrangement takes place, in both the static and dynamic properties of vanadium steels. (*Vide* Proc. Inst. Mech. Eng., December, 1904; Sankey and Kent Smith on the "Heat Treatment of Chrome Vanadium Steels.") The tests chronicled in the records first alluded to were almost entirely static, and much would depend upon the temperature at which forging, &c., was finished, or at which annealing was carried out; many apparent discrepancies would be thus easily explainable.

Accordingly it seemed best to me to begin such investigation *de novo*. Some five years ago Messrs. Willans and Robinson, of Queen's Ferry, Flint., placed at my disposal very complete means of carrying out such an inquiry. This, in the first place, was directed to the observation of different quantities of vanadium upon the static qualities of steels of different carbon content but in other ways similar, all conditions being kept as nearly alike as possible. Two things at once were apparent as the result of this series of comparisons: first the extraordinary intensifying static action of vanadium upon that of another constituent (in this case carbon), and secondly, the "homœopathic" doses in which it was necessary to use that vanadium in order to get the best results. The first at once led me to the conclusion that the useful field for the employment of vanadium by the steel metallurgist would lie much more probably in the direction of quaternary steels than in that of the ternary steels then experimented upon, and the second rendered the use of vanadium commercially possible: for though the cost of vanadium is considerable—its value to-day is a little more than half that of silver—the quantity required being small rendered it possible to produce commercial vanadium steels at costs roughly comparable with those of good quality nickel forging steels. It must always be remembered that it is in connection with this class of steel that vanadium steels must be considered: that is to say, in cases where requirements have to be met that ordinary "carbon" steels are powerless to cope with satisfactorily; and in no way is vanadium likely to enter into those requirements which are at present met with thorough satisfaction by the employment of the best qualities of open-hearth carbon steel. In illustration of the effect of this static action upon quaternary steels I append some results in tabular form, taken from the paper of Captain Sankey and myself above alluded to, exactly such an effect being found as was expected from the ternary tests before alluded to.

Comparative effects of chromium and vanadium on static tests.

Chromium + 0·15 per cent. Vanadium	34·4	52·6	25	55·5

It is not the province of this paper to enter into theories as to the various ways in which vanadium acts upon steel. One such action undoubtedly is to retard the segregation of the carbides. From this it was justifiable to infer that vanadium steels would be excellently suited to the employment of tempering processes; and also by analogy that commercial vanadium steels should be found reasonably free from other segregates. (Naturally I do not allude to those experimental compounds containing high percentages of vanadium which are prone to segregation from quite different causes). But the demands of modern engineering entail more and more dynamic excellence as well as static, and it is evident that in dealing with a special steel particular attention must be paid to the former, for the method of practically summing up the good qualities of a steel by an observation as to its behaviour under steady load or under a slowly applied bending action, obviously cannot be the best guide to its behaviour under widely different conditions. True, the results of simple shock resistance in the majority of cases correspond with the observed static ductility of that steel, but such correspondence is by no means invariable, and it often happens that just such cases may be the cause of "mysterious failure."

It has always been somewhat inexplicable to me why of the four usually recorded static figures, namely, elastic limit or yield point, maximum tensile strength, elongation and contraction of area, the two should have been chosen for generally summing up the strength and ductility of metal (*viz.*, maximum load and elongation), which to my mind have least bearing on the case. For I cannot myself contemplate in constructional or machinery work the useful employment of any material under tension beyond its yield point, while elongation has always struck me as being a measure of longitudinal flow rather than of the true ductility of metal, and to me the contraction of area seems to represent the true static ductility. If there were a constant relationship between the respective pairs of figures, this point would not have any practical importance, but unfortunately—or fortunately—no such constant relations exist. The static ductility is usually further evidenced by a bending test, though it would appear that the most useful and instructive form of bending test is that lately introduced by Captain Sankey, where the sample is alternately bent to 45° in either direction from the perpendicular and not only the number of bends is observed, but also the power required to make each separate bend. Another static test to which but scant attention is generally paid is the behaviour of a metal under torsion, its elastic and maximum shearing stress being observed together with its final twist-angle before shearing.

Now many of the engineering requirements of to-day render it necessary that we should know as much as possible of the behaviour of the metal under kinetic stresses. For example, it is manifestly ridiculous to attempt to sum up by means of the same "quality figures" the suitability of a metal for such different purposes as bridge building and the manufacture of connecting rods. The usual dynamic tests may perhaps roughly be grouped into four classes:—

(1.) The behaviour of a notched bar under sudden and overwhelming shock, such shock being sufficient to destroy the sample tested. Typical tests of this class would be the Fremont and the Izod (W. and R.) tests, recorded respectively in kilog. metres and in foot pounds.

(2.) The behaviour of a notched bar under repeated shocks, each shock being sufficient to permanently deform the sample slightly, the time factor being a somewhat variable item. Such tests are those of Yarrow, Seaton and Jude, &c., recorded usually empirically.

(3.) The behaviour of an unnotched bar under a rapid succession of small and alternating impacts (the time element being rendered practically a constant) until fracture occurs. The most striking examples of this type of test is due to Prof. Arnold, whose method of testing is without doubt of an importance which can hardly be over-estimated.

(4.) The behaviour of an unnotched bar under minute and rapidly applied stresses, applied transversely to the rotating bar, as in Mr. Stead's modification of Wöhler's test, or under repeated alternating stresses longitudinally applied as in Dr. Stanton's connecting rod test, and others of a similar nature. Test of class 3 and of class 4 especially encroach upon considerations of pure fatigue.

From the foregoing it will be evident that investigations which shall lead to the greatest combinations of possible static and dynamic excellence are not to be lightly undertaken in the hope of dismissing the subject quickly as one easy of solution. The diminution in impact resistance is infinitely greater than the increase in static strength in the ordinary steels, the laws of simple arithmetical proportion not applying at all, so that the doubling of the static strength (as evidenced by the elastic limit) with the retaining of the same shock resisting power, means a very great achievement; while, again, a simple ratio of the figures of the alternating test (class 3) is by no means permissible, as the test is carried out under most drastic conditions, and though no "factor" is possible of the actual test figure and the actual life, owing to the varied conditions obtaining in practice, yet it is probable that the length of this life bears relation to some power of the actual alternations figure. Thus a simple ratio of two to one in the test figure at a moderately low power of the numbers becomes thousands to one.

Large numbers of experiments upon the quaternary steels were conducted on the lines alluded to, and as a result the commercial production of five types of chrome vanadium steel was incepted. The application of and demand for these steels is steadily growing and they are now finding considerable use not only in this country but abroad; they are even being exported to France—the home of "special steel" manufacture. But before these types were put upon the market much remained to be done, and an investigation of their static and dynamic properties under widely different conditions of thermal treatment was carried out. Some of the results of this investigation were communicated to the Inst. Mech. Eng., in the memoir before indicated.

The first type of chrome vanadium steel, in the rolled or forged condition, shows an elastic limit of 35 - 38 tons per square inch, together with a contraction of area of 45—50 per cent. It bends and knots double cold, has a shock resisting power equal to that of good carbon steel having much less than half its elastic limit, superior static ductility, and a largely increased power of resisting alternations of stress and fatigue, while its resistance to torsion is much superior to mild or even to nickel "forging" steel. It welds perfectly, retaining its strength in a marked degree. By annealing this steel at 800° C. (very full cherry red), it loses static strength and becomes comparable statically to a 3 per cent. nickel steel, but its dynamic properties have now become stupendous. Its resistance figure to alternations of stress is nearly double that of excellent carbon steel, its resistance to sudden shock is superior to that of the best dead-mild steel known while its static ductility is quite equal to that of the latter, and its resistance to torsion has further improved. By quenching it from 900° C. in oil, and re-heating to 550° C., a material is obtained which has an elastic limit of 45—48 tons per square inch, an ultimate stress of 55—58 tons per square inch, an elongation on 2 ins of 20—24 per cent. and a contraction of 50—60 per cent., together with a shock resistance equal to that of *mild* steel, and an excellent wearing surface. The static ductility of the material is still equal to that of excellent mild steel, while the whole of the original high resistance to alternations of stress and fatigue is retained. Such a combination may be justly described as phenomenal. Thus in dealing with this type of material it is simple to meet most requirements in constructional work. Roughly speaking, if great static strength, great resistance to fatigue, and good ductility are required, together with reasonable resistance to shock (as, for instance, say, in bridge building), then use the material as it comes from the forge, annealing it at a blood-red heat to relieve internal stresses, of course. If one can sacrifice some static strength, and desires to have a material in which resistance to alternations of stress and impact are at a premium (as, say, in a connecting rod or an axle) anneal the material at full cherry-red. If the two sets of conditions are required together as far as is possible (as in the

the employment of a chromometer such as Stead's or Ridsdale's, but fitted with comparison tubes holding 100 c.c. each, and suitably graduated. A steel containing vanadium, in which the per cent. of vanadium has been accurately determined by one of the many methods available is required, and this should preferably be of somewhat the same nature as the samples examined.

One grm. of the sample or samples and standard is weighed out, and dissolved in about 40 c.c. of 25 per cent. nitric acid. When cool it is agitated momentarily with a couple of grms. of sodium bismuthate, and quickly filtered. The filtrate and washings are decolorised with a few c.c. of strong ferrous sulphate solution (acid and about half normal strength), 10 c.c. of fairly fresh hydrogen peroxide solution (prepared periodically by adding sodium peroxide to dilute sulphuric acid added), and the whole made up to 100 c.c. The solutions are compared as in estimating carbon by Stead's method, and a simple calculation by inverse proportion gives the vanadium per cent. True, hydrogen peroxide gives a colour with vanadium which develops somewhat slowly, but all the samples and the standard should be oxidised at once, and it is of no moment whether a solution "develops" its colour in a beaker or the chromometer bottle. Titanium would interfere with the estimation.

In making an investigation such as that of which the practical results are outlined, one has to so impose upon the good nature of one's friends that it would be almost invidious to single out any names for thanks; but, in addition to gratefully acknowledging the kindness of very many workers, I should like to express my thanks to Messrs. Willans and Robinson for placing so many details at my disposal; to Mr. G. N. Frankau, the head of the Queen's Ferry testing department, for valuable assistance; and to my laboratory assistant, Mr. M. H. Lewis, for help in the photographic portion of this paper.

Discussion.

Mr. Max Muspratt asked in what localities vanadium occurred in reasonable quantities. If anything like Mr. Kent Smith's hopes were raised in practice there would be a large demand, and every up-to-date metal works would see if it could not meet that demand. Were there reasonable quantities of vanadium in pyrites or in any of the various modifications of cupreous ores which were found in conjunction with pyrites. He should also like to have some idea as to the quantity of vanadium at present in use in the world. He would further like to know what became of the oxygen which was combined with the vanadium. He took it that the vanadium was used in the form of the pentoxide, and when that came into the group of three principal constituents of steel, it was difficult to know what the fate of the oxygen was. Did it attack the carbides and produce ultimately a steel which contained considerably less carbon than ordinary steel, or, failing that, to what extent would the action of the oxide at a later stage affect the steel?

The Chairman said that when Sir Henry Roscoe made his investigations on vanadium, he believed that his vanadium samples were obtained from the neighbourhood of Macclesfield, in Cheshire. It certainly surprised him to hear that vanadium was almost as widely distributed as arsenic.

Mr. G. Watson Gray said he had found some samples of strontium sulphate from the Bristol Channel district

to contain vanadium. There was no doubt in his mind that some of the discordant results obtained by the early workers on the effects of vanadium on steel were due to the impurities contained in the ferro-vanadium used. Some samples which he had examined contained large amounts of arsenic and phosphorus. As Mr. Kent Smith pointed out at the commencement of his paper, if 0·25 per cent. of vanadium were added to the steel, probably there was only 0·18 per cent. in the product, the remainder being carried away in the slag.

Mr. J. B. C. KERSHAW asked: Were the special vanadium steels made by Messrs. Willans and Robinson being employed at all by motor car makers in this country, and, if so, what amount was used per annum in this way? Vanadium was always used by steel makers in the form of ferro-vanadium, and not as oxide—as Mr. Max Muspratt supposed; and hitherto a firm of electro-metallurgists, in Switzerland, had been the chief producers of this ferro-vanadium alloy. Were Messrs. Willans and Robinson obtaining their ferro-vanadium from that firm, or were they producing it themselves from vanadium ores? Since the Swiss manufacturers had cheap water power available for production of the alloy by electric-furnace methods, it would seem unlikely that we could carry on in this country a successful and profitable business in the manufacture of the ferro-vanadium alloy.

Mr. KENT SMITH said Mr. Carey had partly answered a question when he said that Sir Henry Roscoe's vanadium came from near Macclesfield. Sir Henry was working on a deposit which existed near Alderley Edge, which to-day was of greater academic than practical value. There were various small known sources of vanadium in this country. They were mostly in "pocket" formation. The commercially valuable ores, &c., might be said to emanate from two or three places; the chief one being Spain, where vanadium existed in the form of vanadinite, containing about 3 per cent. of vanadium and 40—50 per cent. of lead. The ore was capable of hand-dressing by the most primitive means, up to about 14 per cent. of vanadium pentoxide—equal to about 8 per cent. of vanadium. There were also deposits in Yauli, where the metal existed in anthracite coal. The ash contained 45—50 per cent. of oxide of vanadium. It was necessary to burn 50 tons to obtain a ton of ash, and thus to burn 100 tons of coal to get a little over a quarter of a ton of vanadium. He believed that a French syndicate, who were working that deposit, had not been very successful. The coal was in a very inaccessible place, and transport difficulties were great, while many other circumstances were unpropitious. The Colorado sandstones contained vanadium. Sandstone would appear simpler to treat than lead ore, but it was a very difficult ore of vanadium to work. A considerable quantity of the ore was being shipped to England, he was told, and several people had experimented on it. He believed a works was being built for extracting that ore alone. With regard to the quantity used now, as already stated, in Queen's Ferry spring steel there was about 0·2 per cent., while in Queen's Ferry case-hardening steel, there was rather over 0·1 per cent. Supposing that the average grade contained 15 per cent., 3½ lb. of metallic vanadium were used to the ton; if 33 per cent. alloy was used, 10 lb. of alloy were required to the ton. A very much better quality of vanadium steel could be obtained, especially "dynamically," than nickel steel at the same price. He did not think that pyrites offered a very likely source. A sulphide of copper occurred abroad with which was associated a considerable amount of vanadium, but it was a difficult material to treat. The chief firm in this country using vanadium in large and regular quantity was Willans and Robinson, of Queen's Ferry. In reply to Mr. Max Muspratt, the metal, and not oxide of vanadium, was used in steel making. The oxygen had been got rid of or been dealt with long before the alloy reached the steel. He did not attach the same importance to the presence of arsenic as did Mr. Gray. Supposing a vanadium alloy contained 30 per cent. of vanadium and as much as 3 per cent. of arsenic, the introduction of 0·15 per cent. of vanadium means introducing 0·015—0·020 per cent. of arsenic. Ordinary steels contained, perhaps, 0·03 per cent. of arsenic, making a total of 0·05, which was not harmful. He quite agreed with Mr. Gray as to phosphorus determination. The method he had found best was to almost reduce the solution of the steel precipitate with ammonium acetate, filter, redissolve, reprecipitate with ammonia, add hydrogen peroxide, filter and then precipitate with molybdate. Mr. Kershaw spoke of the motor car industry. It would be safe to say that of the vanadium steel turned out at Queen's Ferry about 80 per cent. was absorbed by the motor car industry.

MR. HENRY HOWARD IN THE CHAIR.

COMPOSITION AND PROPERTIES OF COTTON SOFTENERS.

BY F. E. BURNHAM.

The process of dyeing tends to harshen fibres, and therefore methods and materials are sought which will reduce this tendency to a minimum. The harshening effect is especially noticeable in the dyeing of cotton warps, and efforts to overcome the trouble have resulted in a demand for a class of substances known as cotton softeners. Cotton softeners may be defined as substances designed to reduce or prevent the harshening effect of the dyeing process on cotton yarns. To a limited extent softeners may be used in dyeing raw stock and carded cotton; for piece goods their use is unnecessary, as the desired result is obtained in the finishing processes, and by the use of various finishing compounds. The commercial importance of cotton softeners is considerable, yet an examination of the literature of textile processes discloses slight information, and has led the writer to believe that the results of his investigation of the composition and properties of cotton softeners may be of interest. A preliminary examination shows that, in general, commercial cotton softeners are composed of water, soap, and oil, or, as it may be considered, an emulsion of oil in a concentrated solution of soap. Other substances may be present, but, with the exception of glycerin, are of no value, and should be regarded as adulterants; examples of such substances are sodium silicate, rosin, starch, and clay. Both soda and potash soaps are used according to the properties desired in the softeners. For a cheap softener the lower cost of the soda soap recommends it, and, when used with an oil of low melting point, fairly good results are obtained, especially if there is much glycerin present to furnish the rather essential property of hygroscopicity. The hardness of the soda soaps also gives a certain body to the fibre. In general, however, soda soap softeners are not so efficient as the potash soap softeners, because the soda soap has a tendency to dry out, and thus harshen the feel of the fibres rather than to produce the contrary and desired effect. A certain advantage which soda soaps possess, however, should not be overlooked, *viz.*, that because of their solidity they form a protective covering over the oil in the fibre, and thus prevent its turning rancid. Because potash soaps are soft and deliquescent they are generally to be preferred as softeners, their superior efficiency off-setting the lower cost of the soda, but by reason of the tendency of many oils to go rancid and develop disagreeable odours, the range of oils which it is possible to use with a potash soap is more limited than is the case with soda soaps. The choice of the alkali in the soaps used, however, is dependent, to a large degree, on the oil used, whether present as combined fatty acid, or as free oil. Mineral and fish oils are necessarily excluded; the former because they are unsaponifiable, the latter from the bad odours developed on drying them, and because of their gumminess. The field of animal and vegetable oils is a wide one, with cost an item of much importance. Olive,

cottonseed, maize, sunflower, peanut, palm, and coconanut oils are all feasible vegetable oils. Tallow, both beef and mutton, lard, tallow oil, red oil and lard oil, are all suitable animal products. The selection of a suitable oil is dependent on the cost, the melting point, the freedom from tendency to turn rancid, and the absence of unsaponifiable matter and hydroxy acids. All desirable properties cannot be expected in one oil, and the purpose for which the softeners are used will determine the choice.

While in general the use of a softener is simply to produce a good touch, yet different kinds of yarn will require slightly different treatment, and the softener be modified accordingly. Low quality yarns require the item of cost to be especially considered, and so the soda softener will be employed in such cases. For loosely twisted yarns and short staple yarns, the body-giving property of the soda soap softener recommends it. All fine yarn, tightly twisted yarns, and those from unusually harsh dyeing processes will require the potash softener. The proportions of the different constituents of a softener, *i.e.*, the water, soap, and oil, may be defined as follows:—sufficient water to dissolve the soap, and as much oil as this concentrated soap solution will thoroughly emulsify. The fact that the above conditions are frequently not observed—commercial cotton softeners being often simply mixtures of soap and water selling at prices greatly above their true market value—has led many to consider that all cotton softeners are "fake" products. No general rule governing the proportion of water, soap, and oil is followed, hence an investigation of the application and effect of softeners of varying proportion on warps became necessary.

Softeners were made up in the laboratory in accordance with the rule stated above, that the water should be sufficient to dissolve the soap, and no more oil should be present than could be held thoroughly emulsified, and the results from using such softeners, compared with those obtained by the use of commercial softeners. It was soon evident that there was too much oil in the majority of the commercial softeners, as it separated in the softening bath, and frequently caused oil stains and streaked warps. As indicated by their composition, there are two methods of preparing cotton softeners; first, by adding a warm solution of caustic alkali to an excess of oil above that required to make a neutral soap, and then thoroughly boiling and agitating; second, by making a soap, dissolving it in hot water, and adding the proper amount of oil, and then boiling and stirring the mixture. With the first method it is evident that the combined fatty acid and free oil must be the same. By the second method it is possible to have one variety of soap, *e.g.*, a palm oil soap, and a different oil, *e.g.*, olive oil; such combinations are frequently desirable both from an economical and from a practical point of view. A further advantage of the second method is that the free oil in the softener is not boiled for the long period required by the first method. When a soda soap is used because of its hardness, the free oil must be of low melting point, and unquestionably a good grade of olive oil is the most desirable for such purpose. With a potash soap, because it is soft, a harder fat or tallow may be used for the free oil. The use of these fats is also preferable as they have less tendency to turn rancid. The proportions determined by experiment, as best suited for cotton softeners, were those in which the soap, calculated on a dry basis, is three parts to one part of free oil, or, including the water, seven parts of water, three parts of soap, and one part of oil. An analysis of a soda softener made approximately on this formula gives:— Water, 64·2 per cent.; dry soap, 26·8 per cent.; oil, 9·0 per cent. A potash softener, which gave excellent results, gave on analysis:—Water, 68·4 per cent.; soap, 23·7 per cent.: oil, 7·9 per cent.

As stated above, with a soda softener olive oil is preferable for the free oil, but as a source for the combined fatty acids in the soap there is a wide range for choice; at present maize (corn) oil is a very cheap and valuable soap oil, and may even be used as a free oil with fairly good results. Bleached palm oil, however, is the usual fatty base of the soap in soda softeners, the body it gives being the reason for its selection, as thereby more water can be included in the softener. From a user's standpoint it is not superior to maize oil or tallow, and is somewhat more expensive. Cottonseed oil is on the whole less desirable in its soap making properties than maize oil, and at the present time is higher in price. For a potash softener the maize oil is suitable, and is as cheap as the fatty base for the soap, if a fairly hard tallow is used for the free oil. Red oil is also very suitable as a soap base with either potash or soda, but because of its odour should not be used for the free oil. Lard oil, while suitable for soap base, is higher in price, and offers no advantages over red oil. Beef and, in a less degree, mutton tallow are good and cheap soap bases, and beef tallow is the material *par excellence* for the free oil of a potash softener. One cotton softener, which is somewhat largely used, is sulpho-ricinoleic acid or Turkey red oil. This is, undoubtedly, a good softener, and has, in a marked degree, the general property of all good cotton softeners of brightening colours. It is, however, more expensive than the cotton softeners described, and has no compensating advantages.

It may be summarised in conclusion that a good cotton softener is composed of approximately seven parts of water, three parts of soap, and one part of oil, and that, where a soda soap is used, the free oil should be olive or maize oil, and, when a potash soap is used, it should be tallow or lard.

Meeting held at Boston, U.S.A., on Friday, March 2nd, 1906.

MR. F. E. ATTEAUX IN THE CHAIR.

COLLABORATIVE WORK ON TANNIN ANALYSIS.

BY FRITZ H. SMALL.

The tanner's original methods of analysis were primitive, and largely consisted of chewing the bark or tasting the liquor. It is little wonder, therefore, that it was regarded a remarkable feat to turn out leather of uniform quality. Many methods have, to be sure, been proposed for estimating tannin, belonging mainly to one of two groups—either (*a.*) precipitation with metallic salts, or (*b.*) with some form of gelatin.

Under (*a.*) have been suggested ammoniacal copper acetate, ammoniacal zinc acetate, lead acetate, stannous chloride, ferric acetate and other salts. Under (*b.*) various methods depending upon the use of gelatin or raw hide. Also Wagner has suggested the use of cinchonine sulphate, using Magenta as an indicator, and others have suggested various oxidation methods; but none of these methods were founded on accurate chemical knowledge. They were essentially empirical, and in general gave results of a fearful and wonderful concordance.

The first method that came into anything like general use was that of Löwenthal, originally published by him, in 1877, in the "Zeitschrift für Analytische Chemie." This was carefully studied by a commission of German chemists, who, in 1885, reported a formula for its use, which latter was advantageously modified by Hunt and Procter. In general the method consists in titrating the tannin solution in the presence of Indigo Carmine with a solution of potassium permanganate, whereby the tannin is oxidised, the Indigo serving the double purpose of regulating the oxidation by confining it to bodies more readily oxidisable than itself, and of acting as indicator. The method has some value, but also serious defects and is no longer in common use. The foundation of the methods in practical use to-day was the method proposed by Simand and Weiss in 1885. Its essential features were as follows:—The tannin solution was made up to contain from 1 to 1·2 grms. of solid matter per 100 c.c. of solution, the exact amount being determined. To 250 c.c. of the solution so prepared was added 1 grm. of powdered dry raw hide and the mixture allowed to stand several hours with occasional shakings. It was then filtered through linen. To the filtrate was added another grm. of the powdered hide and the process repeated. Then another grm. portion was added, and finally a 2-grm. portion, which was allowed

to stand some 12 hours or more. 100 c.c. of the final clear filtrate were evaporated and dried, and the difference in weight between this and the original reckoned as tannin. In 1887, Prof. Procter suggested packing the powdered hide in a tube, and allowing the tannin solution to percolate through it, whereby the tannin is removed and a clear percolate free from tannin results. This suggestion of Prof. Procter is the basis of the standard method used in the Eastern Hemisphere. In 1894, Mr. Yocum suggested putting the hide powder into the liquor and shaking vigorously in a mechanical shaker. This suggestion is the basis of the method used in America. The method in either form appears simple, but it is evidently a purely empirical method, dealing with substances whose properties are little understood, and in reality it abounds in difficulties.

Several schools for the study of matters pertaining to the tanning industry have been founded, notably at Vienna, Freiburg, Leeds, and London, and in these has been done most of the original work on methods. In America there has been no such school, and, until the recent establishment of the Leather and Paper Laboratory at Washington, no institution devoted any time to this kind of problem. It has consequently been necessary for the men actively engaged in helping to make leather to work out their own method. Realising the necessity of a uniform method, whereby concordant analytical results could be obtained, several of these leather chemists in 1894 banded together and were admitted to the "Association of Official Agricultural Chemists," as the section on tannin, under which organisation they have done much towards perfecting a method of tannin analysis.

In 1897 a meeting of leather chemists was held in London and an "International Association of Leather Trades Chemists" formed. Its object, as announced in its constitution, is to "establish standard international methods for the valuation of all materials used in the leather industries, especially as regards the drawing of samples from bulk, the processes of analysis employed, and the form in which their results are to be stated. It further aims at promoting scientific and technical knowledge in the industry, and especially at the improvement of scientific methods of control of the processes of manufacture." It is a strong organisation with some 250 members, about evenly divided between active and associate, and belonging to nine countries. It has a meeting once in two years, at which the work during the preceding interval is thoroughly discussed, and any desirable changes in the method in vogue adopted and made official. Its methods of analysis are standard for the continental countries. It publishes weekly an eight-page sheet called the "Collegium," which is the official organ of the association, and which contains both original articles and reprints of articles on subjects relating to the tanning industry. In 1903, several leather chemists, who had been associated in the tannin section of the Association of Official Agricultural Chemists, formed a separate organisation, known as the "American Leather Chemists 'Association." This now has a membership of 50, of which 30 are active.

For purposes of leather manufacture the tanner wishes to know what percentage of tannin his raw material contains and what is the composition of the liquor he obtains on leaching this raw material. There is, therefore, for the chemist—first, the problem of extracting the tannin from the raw material on a laboratory scale. Abroad the percolation method is in favour. Parker and Payne, in England, have made a rather thorough study of extraction by this method, and have concluded that for each material there is an optimum temperature at which the yield of tannin is greatest, and they have worked out for numerous materials this optimum temperature. Some doubt has been cast on this conclusion by work done last year by members of the "American Leather Chemists' Association," but the question is still open. In America the method in common use has been to extract the ground material in a copper Soxhlet apparatus. Some collaborative work on extraction by the "American Leather Chemists' Association," in 1904, showed rather wide variations in results, and an investigation of the reasons has since been undertaken. At the start it was found necessary to specify a certain maximum fineness to which all of the material to be extracted must be ground, if it was to be completely extracted in a reasonable time. Next, the Soxhlet apparatus, as ordinarily used, was found to give low results in tannin, probably because of the prolonged boiling of the liquor whereby a conversion of the tannin into some compound not tannin, possibly gallic acid, takes place; for instance, some recent experiments made in duplicate in the writer's laboratory where a sample of tannin material was extracted in a Soxhlet apparatus, the extractive in the one case being removed from the action of the heat, and in the other allowed to boil in the usual way, showed the following results:—

Myrobalans.

	Boiled.	Not Boiled.
Soluble solids	67·80	66·64
Non-tannins	28·99	17·65
Tannin	38·81	48·99

Valonia.

	Boiled.	Not Boiled.
Soluble solids	54·03	54·34
Non-tannins	19·86	16·46
Tannin	34·17	37·88

In each case the total yield of extractive was similar, but the prolonged boiling brought about a very serious loss of tannin. Several pieces of apparatus have been brought out during the past year to overcome this difficulty, notably by Messrs. Teas and Reed, and Mr. Veitch has done some valuable work along the same line. The whole question is in the hands of a committee for elucidation during the present year and some very interesting results may be expected.

Next, as regards the analysis of the tannin solution—in outline the method used is as follows:—the tannin solution is made up of such concentration as to contain from 0·35 to 0·45 grm. of tannin to 100 c.c.; 100 c.c. of this solution are evaporated and dried to give the amount of solid matter present. Some of the solution is filtered and 100 c.c. of clear filtrate evaporated and dried to give the amount of soluble solids present. Another portion of the solution is treated with hide powder to remove the tannin. The hide powder is then filtered out and 100 c.c. of the clear filtrate evaporated and dried to get the amount of soluble matter present which is not tannin. The difference between the weights of the first two residues gives the amount of insoluble matter present, and the difference between the last two the amount of tannin present. In carrying out this scheme of analysis the first difficulty arose in trying to filter out the insoluble matter. The solution is of a colloidal nature and filter paper fails in many cases to yield an optically clear filtrate even after many hours of repeated returns through the paper. The insoluble matter is, moreover, only relatively insoluble, as it is distinctly susceptible to the influence of temperature; for instance, a solution of tannin from hemlock bark filtered at 15° C. showed 4·23 per cent. insoluble, at 20° C. 3·53 per cent., at 25° C. 2·76 per cent., at 30° C. 2·21 per cent. Further, most of the usual filtering materials will combine with tannin to a certain extent and so remove tannin as well as insolubles from solution. This loss may frequently amount to several units per cent. These various points have been brought out in the collaborative work of the years past, and now by a careful prescription of conditions a method has been arrived at, which at least enables us to secure results that are reasonably concordant. The worst trouble, however, in the scheme of tannin analysis has been to remove the tannin and measure its amount. The method in vogue in America, as has been previously stated, is to shake vigorously some carefully prepared powdered hide with some of the tannin solution. Now,

no matter how carefully the hide powder is prepared, some of it is found to be readily soluble in water, or in the dilute solution of tannin employed for analysis. Further, for some inexplicable reason, it has been found impossible to prepare duplicate batches of hide powder having the same absorptive power, no matter how carefully the conditions of manufacture are duplicated. It was not until a paper by Mr. Craighill, acting on the suggestion of Mr. Weiss, published in the "Leather Trades Review," brought out the advantage of treating the hide powder before use with a solution of chrome alum, that any approach to uniformity of analysis was arrived at. Curiously enough a previous tanning of the hide powder with the chrome salt not merely largely converts the soluble hide into insoluble compounds without diminishing the power of the hide powder to absorb vegetable tannins, but it equalises the absorptive power of two powders, which before treatment with the chrome salt were very unlike. Thus two samples of hide powder tested in the writers' laboratory gave results for non-tannin material in an identical solution, varying by over 3 per cent. After these two samples of hide powder had been subjected to the preliminary chroming they gave results agreeing to within less than one-half per cent. This discovery has brought order out of chaos to a remarkable extent, and the agreement of the non-tannin values in the collaborative work done during the past few years has been very satisfactory.

The present method involves treatment of the hide powder with a dilute solution of chrome alum, then washing the hide powder free from uncombined salts, squeezing out the excess of water and adding the moist chromed hide powder to the tanning solution, which, of course, necessitates a correction for the water added with the hide powder. As these operations have to be performed each time an analysis is made, it is evident that if a hide powder could be prepared which would have the advantages of the chromed hide powder and yet be ready for use at once, it would be distinctly desirable. This is one of the matters under consideration at present, as well as certain questions affecting the details of the present process. Even the evaporation and drying of the residues in the analysis has been a source of much discordance. It has been found extremely difficult to remove all traces of moisture without bringing about a decomposition of some of the substances present in the residues. A vacuum oven might probably have done this satisfactorily, but the apparent impracticability of bringing about its universal use was against it. The difficulty seems to have been solved by the use of the combined evaporator and dryer worked out by Mr. Alsop. This consists of a copper steam bath with solid top on which the dishes rest, and a steam jacketed cover, provided with openings for ventilation, which fits down closely on to the copper top. A uniform temperature of about 98° C. is attained, and the tests of the apparatus made by Mr. Reed show that the drying is uniform over the whole top of the bath, and that after complete drying is attained, which happens in some 12 hours, no further effect of decomposition or otherwise is produced by further drying, but a constant weight is attained. The collaborative tests so far made seem to corroborate these results of Mr. Reed.

As a result, then, of the collaborative work which has been done, and of which I have been able to give only a partial and brief sketch, we have a very fairly satisfactory method for valuing the raw tanning materials. It is now possible to buy and sell such on the basis of their tannin content with the assurance that on the same sample the results of two chemists will show a very close agreement. It is also possible now to regulate the actual manufacturing processes with a degree of certainty unknown in the past.

But the work of the American Leather Chemists' Association has not been confined wholly to this one subject. It has greatly broadened out, and it is hoped and expected that its work will continue to expand. This year, for instance, in addition to the work on extraction and on the analysis of fresh solutions of tannin, work is in progress on a method of analysis of the old used liquors of a tannery, the analysis of these being complicated by the presence of acids and of excessive amounts of non-tannin material; also on the estimation of the amount of acid in these liquors and the kind, both matters of great importance to the tanner. Similarly a Committee is studying the best way of estimating the colour value of tanning materials and it is hoped to devise some method of recognising the different kinds; that is, for instance, determining how much chestnut wood and how much oak bark liquor is contained in a mixture of the two. Another Committee is formulating a method for the analysis of commercial acids in use by tanners. Still another Committee is examining the new methods proposed for the analysis of tannin; and, finally, the study of methods of analysis of the materials entering into the manufacture of chrome leather is being entered upon. As fast as these Committees arrive at results their recommendations are submitted to trial on identical samples by the active membership of the Association, and any others interested. In this way the valuable results of the past have been achieved. The process is somewhat slow, but it seems well calculated to save out the good and reject what is bad. It is to this spirit of collaboration among the leather trades' chemists that we may ascribe the present vastly improved condition of questions of analysis of tannery materials.

New York Section.

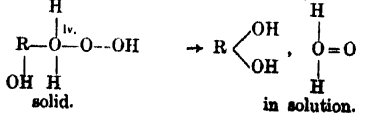
Meeting held at the Chemists' Club, on Friday, January 19th, 1906.

DR. RUSSELL W. MOORE IN THE CHAIR.

EARTH ALKALI AND ALLIED PEROXIDES: PROPERTIES AND APPLICATIONS.

BY DR. R. VON FOREGGER AND HERBERT PHILIPP.

Recently a group of oxidising compounds which, on account of their chemical and physiological properties, are of industrial interest, have been commercially procurable. The products we refer to, and which we have studied, are the peroxides of calcium, strontium, magnesium and zinc. We have not included barium peroxide, as this compound is already well known, and, besides, it would not fit in this class on account of its toxic nature.



The ideal oxidiser would no doubt be ozone, because as soon as it has accomplished its functions its carrier—oxygen—escapes as a gas, and, therefore, leaves no residue. But ozone cannot be conveniently compressed, and, therefore, can only be used at the point and place of production.

The peroxides we have in mind come nearest to the above property of ozone, inasmuch as in liberating their available oxygen they leave either a colourless solid residue, which can readily be separated from the oxidised medium, or a soluble salt, both of a harmless nature.

There are many compounds known for their oxidising properties, which have proved to be applicable in certain lines, yet, due to some of their characteristic and unpleasant properties, have failed to score in other lines. It is the destiny of these earth alkaline peroxides, with their non-toxic, non-irritant, and non-corrosive actions, to enter upon these lines.

The constitution of these earth alkaline peroxides can be most easily explained by accepting a tetravalent oxygen (Kingzett, this J., 1890, 3, and Chem. News, **46**, 141). If R represent a bivalent metallic element, the peroxide is represented thus:—R=O=O, the tetravalent oxygen being the active oxygen, which we can imagine has wedged itself between the metal and bivalent oxygen of the ordinary oxide.

The hydrates of the peroxides would have the formula $R(OH)_4$, and, as we will show later, we imagine these perhydrates in solution as $R(OH)_2$, H_2O_2, and think we can demonstrate this in the following way:—

This tetravalent oxygen, which we imagine as lightly wedged in between the R and bivalent O, is ready to step out with ease, as the opportunity offers itself, thus explaining the characteristic oxidising properties of these peroxides.

Calcium peroxide.—A calcium peroxide is described in text-books with the formula $CaO_2 8H_2O$. This is the product as it is obtained, for instance, by the action of hydrogen peroxide on lime water. It appears in fine needle-like crystals, and is very voluminous. In that form, however, it has not found any industrial application. The product as it is procurable for industrial purposes is free from molecular water, and is a compound of calcium peroxide and calcium hydroxide in the form of a fine yellowish white powder. It is considerably higher in its contents of available oxygen than the crystalline product. Besides these two bodies, a third intermediary one is known, containing two molecules of water. This forms a compact, comparatively stable body, which has a different appearance from either of the two, as the crystals are extremely small. The dehydrated product can be brought back to the hydrated form with evolution of heat. It forms both hydrates, the $CaO_2, 2H_2O$, and finally, the $CaO_2,8H_2O$. De Forcrand (Compt. rend., **130**, 308; this J., 1900, 683) has found that on an average, about 3 calories are evolved by the addition of each molecule of water.

The dehydrated product is ordinarily a 60 per cent. peroxide with 13·5 per cent. available oxygen, but an 80 per cent. peroxide with 17·8 per cent. available oxygen has also been obtained.

The density of calcium peroxide preparations with an equal percentage of oxygen can vary apparently owing to the mode of manufacture. The density also varies according to the amount of calcium peroxide, the more peroxide being present, the denser the body. A product of 60 per cent. peroxide shows, on an average, the sp. gr. of 0·603, while a product of 80 per cent. we have found to have a sp. gr. of 0·74.

A line must be drawn between the solubility and dissociability of the product in water. Regarding the first, but 1 part dissolved in 7·025 parts of water at 20° C. Regarding the latter, however, it was found that from a calcium peroxide with 13·5 per cent. available oxygen, stirred in 150 c.c. water during five minutes at 10° C., 2·6 per cent. at 20° C., 2·97 per cent. and at 40° C., 8 per cent. of the total available oxygen was found by titration in the solution.

From this, the amount of dissociated oxygen is out of proportion with the solubility of the product, which can be explained by a molecular change taking place, bringing the available oxygen into an active state. Furthermore, as this oxygen in solution appears very stable, even at boiling, it must be assumed that it is there *not* in the form of free hydrogen peroxide, but as an addition to calcium hydroxide. Evidently, when the peroxide is added to the water it forms a compound with 2 mols. of water, which undergoes a molecular change when it goes into solution; thus, $CaO_2,2H_2O \rightleftharpoons Ca(OH)_2,H_2O_2$. This latter product finally splits up by heat, but at lower temperatures is formed again, thus, $Ca(OH)_2,H_2O_2 \rightleftharpoons Ca(OH)_2 + H_2O_2$, exemplifying a reversible reaction, the former equation also being of a reversible nature.

We have found that complete decomposition of calcium peroxide in aqueous solution is only obtained after boiling the same for at least six hours. It seems to be the most stable of the alkaline earth peroxides. In a dry atmosphere it is so stable that by heating up to a temperature of 200° C. it does not decompose.

Calcium peroxide seems to be non-explosive. Mixed with animal charcoal in equal parts, and detonated, it did not explode, and also on adding a few drops of concentrated sulphuric acid no combustion or explosion occurred, as is the case with chlorates and permanganates. It is readily soluble in inorganic and organic acids, forming a calcium salt and hydrogen peroxide. It is stable with organic acids; during the reaction of equivalents in the state of formation, the activity of the available oxygen is very efficient. The amount of the available oxygen in commercial calcium peroxide compared to the amount of available oxygen in the commercial 10 vol. hydrogen peroxide preparation stands in the ratio of 10 : 1.

At the Bethlehem meeting of the American Electrochemical Society last September (Eighth General Meeting, see Electrochem. and Met. Ind., 1905, 3, 377), an interesting discussion on the comparative values of calcium peroxide and calcium permanganate was started. In a neutral or alkaline solution of calcium permanganate with the formula $Ca(MnO_4)_2,5H_2O$, 1 mol. furnishes three atoms of available oxygen, or 13·2 per cent. In a sulphuric acid solution, 1 mol. of calcium permanganate furnishes five atoms of available oxygen, or 21·7 per cent. One mol. of calcium peroxide furnishes one atom of available oxygen, which, we have seen, amounts to from 13·5 to 17·8 per cent.

So, concerning the amount of available oxygen, calcium peroxide stands between the two. Concerning the character of the reaction, however, calcium peroxide may be considered preferable, as a sulphuric acid solution of this peroxide yields nothing but nascent oxygen, or hydrogen peroxide, and as the only by-product, calcium sulphate, of which but traces go into solution, and the white sediment will only in rare cases be objectionable; whereas, the manganous salts formed by the permanganate reaction are usually considered objectionable.

Calcium permanganate is of a very deliquescent nature. Although it has been tried, to use the product industrially the fact that it decomposes so very easily in the presence of organic substances, and that it is hygroscopic, place a barrier to its industrial success, though it could be manufactured very cheaply as a by-product of Weldon mud. It has only been used for purifying water, first suggested by Bordes (Woch. f. Brau., 1895, 1063).

Strontium peroxide.—This product is also a microcrystalline body—$SrO_2,8H_2O$. As with calcium peroxide, the commercial product is dehydrated, containing 85 per cent. SrO_2, the balance being strontium hydroxide. It is a voluminous white powder, of sp. gr. 0·546. Its solubility, calculated on the amount of strontium, is one part in 12,500 of water, at 20° C. Its capability of dissociating its oxygen is, however, decidedly higher than that of calcium peroxide. We have found that in an interval of five minutes, in 150 c.c. of distilled water, at 10° C., 12·4 per cent.; at 20° C., 15·78 per cent.; and at 40° C., 26·3 per cent. of the total available oxygen could be titrated in the solution. The residue of this latter solution was dissolved and the titration showed only 62·2 per cent. of the total available oxygen; about 11·5 per cent. of the total available oxygen had apparently escaped by the heating to 40°.

Strontium peroxide is, like calcium peroxide, very stable in a dry atmosphere, even at a high temperature, and can be heated up to 150° C. without loss in available oxygen.

Magnesium peroxide.—Magnesium peroxide is a white, amorphous powder, which, we think, is in reality a perhydroxide of magnesium. Magnesium peroxide as it is obtainable in the market, is a compound consisting of magnesium perhydroxide, magnesium hydroxide and constitutional water. We do not think that it is a mixture, because we have noticed that preparations containing certain amounts of available oxygen are more stable than other preparations containing more or less than these. Thus, a product containing 9·2 per cent. of available oxygen seems to be stable, whilst if a product contains less than this it gradually loses its available oxygen, till it reaches 8 per cent. available oxygen, when it again remains stable; and so we have found stable products containing 6·85 to 6·9 per cent., and also such containing 4·3 per cent. oxygen. The less available oxygen the product contains the more stable it is under atmospheric conditions. The ordinary product contains about 8 per cent. oxygen and has a sp. gr. of 0·615.

Magnesium peroxide has the solubility of 1 part in 14,550 parts of water at 20° C. Suspended in water it dissociates its available oxygen quicker than zinc peroxide, and slower than calcium or strontium peroxides, but it loses its available oxygen quicker in moist atmosphere than the other peroxides, as it is apparently more subject to the influence of carbon dioxide. In a dry atmosphere it is, however, comparatively stable, and was heated to 160° C. without any loss.

It reacts like these other peroxides with acids and certain organic matters.

Zinc peroxide.—We have found this peroxide of a rather steady constitution, the percentage of peroxide only varying according to its contents of free moisture. It seems to form no perhydrate, and, apparently, contains also no constitutional moisture. In that it differs from calcium and strontium peroxides. It represents, we believe, a mixture of zinc peroxide—averaging 50 per cent.—zinc hydroxide and free moisture. This 50 per cent. peroxide is a dense, yellowish-white powder of sp. gr. 1.571. The product of this form is very stable, and does not lose its available oxygen when heated up in dry air to 170° C. At a temperature of 100° C., the moisture evaporates without affecting the product itself, so that by this procedure the substance gains in percentage of peroxide.

Zinc peroxide suspended in water is very permanent and very slightly soluble (one part in 45,500). In acids of any kind it is readily soluble. Organic matter, if moist, or if acid in reaction, decomposes it gradually. It is indifferent to mineral hydrocarbons, inasmuch as they contain no free acid. This characteristic is essential for the preparation of ointments, a form in which it is widely used.

Zinc peroxide is a product of highly antiseptic properties, and has the advantage over other antiseptics of being odourless and non-irritant. As it is exclusively used in surgery and dermatology, we refer to the literature in existence.

Applications.—As to the application of these peroxides, one would imagine that the peroxide containing the most oxygen would be the most economical in use. Such, however, is not the case. A great advantage of these oxidising agents lies in the property that their carrier, the basic radical, is also suited to take part in the reaction.

For industrial purposes, calcium peroxide will be the one most preferred, not only on account of its large quantity of available oxygen, but on account of the property of calcium to form so many insoluble salts; whilst for physiological and chemical reactions, magnesium, strontium, and zinc peroxides are very desirable, on account of the simplicity with which their mild alkaline basis carries the available oxygen to the place where they produce autoxidation.

As the bleaching of oils should most conveniently demonstrate the oxidising power of peroxides, our experiments regarding the practical use of these products were first directed to this field. A stimulation to try them was given by the suggestion of some oil experts that sodium peroxide would be a splendid bleaching agent for oils, if its liability to set fire to organic substances under certain conditions did not call for too cautious handling, and if its saponifying properties were not so strong. These two objections, the first of which it may be said is imaginary, are entirely obviated with calcium peroxide. There is no danger whatever in handling this peroxide, and no saponification takes place.

Our experiments are merely of a suggestive nature, and it is therefore reserved for the oil expert to complete, or to entirely remodel our method provided our preliminary trials offer enough inducement.

The first trial was made on cottonseed oil, with a CaO_2, $8H_2O$, the fluffy voluminous form of which promised to be advantageous. Sulphuric acid, 66° B, was first stirred into the oil for half an hour, and then, while constant stirring, ½ per cent. of the peroxide was added. In a few minutes the dark brown colour due to the action of sulphuric acid had changed into a light greenish brown, and after a one to two hours' continuous run, the oil had the desired shade. After 24 hours the oil was filtered. The oil thus treated, however, had no keeping properties, and darkened considerably after a couple of months.

We will not go into the details of the series of experiments, which proved in many respects to be of value for the knowledge of the chemical properties of calcium peroxide, but confine ourselves to stating that the final outcome of tests was a complete reversal of the above process. We found that in adding the peroxide first, and then liberating its available oxygen by means of sulphuric acid, the bleaching was instantaneous. A 60 per cent. calcium peroxide was used, and the process as we now recommend it is as follows:—

Add, while stirring the oil, about 0·1 to 0·5 per cent. in weight of peroxide. Following this, slowly add about 0·2 of sulphuric acid, 66° B. The reaction is visible; the oil, which would turn black by the addition of sulphuric acid, becomes light at once; when all the acid is added the bleaching is also completed, so that the whole process only last about ten minutes; even after an hour, the difference in the shade will be very slight; should the oil come out slightly cloudy after filtration, the addition of 0·1 per cent. of sodium carbonate or unslacked lime will completely clarify it. To our knowledge, such a 10 minutes' bleach is something new, and the process, therefore, is worthy of being considered, with all its advantages. Besides the economy in time, this method will prove to be a great saving of material, in that the waste of oil produced by the slimy residue is but small compared to that produced by, for instance, the fuller's earth process. The condition of oil is satisfactory; it has a pure fresh flavour, which it does not lose after standing a half year, exposed or bottled, and in darkness. We also found that oil with a rancid flavour or taste is restored by the oxidation. The use of sulphuric acid cannot be objectionable if it is employed in the above way, as it is not allowed to affect the oil, and as the gypsum formed in the reaction settles quickly.

We believe that no harm is done to the oil by this process, nor is there any harmful or foreign substance introduced which might prevent it from being used as an edible oil.

During the course of the experiments it was found that the economy of work depends greatly on the finely powdered state of calcium peroxide. Only under this condition is the reaction with the equivalent of sulphuric acid an instantaneous and a complete one. If the powder is granular or lumpy, it was found that up to 30 per cent. of it is wasted, on account of the slowness of reaction. Experience further proved, that the highest efficiency is obtained with the most abrupt discharge of active oxygen, and in order to accomplish this, we have so far not succeeded in finding any other re-agent than the concentrated acid. Several acid salts, the best of which are sodium bisulphate or sodium bicarbonate, which react with the peroxide in aqueous solution, will not efficiently react on the oil, and heat alone does not produce decomposition. A 50 per cent. sulphuric acid solution was established inefficient. On the other hand, if after the acid reaction a trace of water was added, say, 1/10 per cent., the bleaching effect was slightly improved, with the disadvantage, however, that the oil was then more apt to turn out cloudy. No test was made with an 80 per cent. peroxide, but it is right to assume that with it the proportions of the two re-agents used are reduced at least 25 per cent. With olive oil similar results are obtained, as with cotton seed oil. It must be mentioned that with different grades of the same kinds of oils the degree of bleaching varies. In a similar manner this bleaching process is applicable to fats, glues, and gelatins, and we notice that, beside the bleaching effect, there also takes place, to some extent, a deodorisation and a preservative action, the cause of which is clear enough without explanation. As to the treatment of linseed oil, for which, naturally, a good oxidising agent is in place, we will reserve a special report for a later date.

As oxygen is the most natural disinfectant, and as the germicidal power of active oxygen has been established, the question suggests itself whether some of these non-toxic peroxides are useful for sterilisation and preservation. There is, too, to recommend them, the harmlessnes of these products. The fundamental motive of all the work that has been done in that direction, and that remains to be done, is the fact that an efficient and non-injurious method of sterilising and preserving food substances is not yet known. All who are following with interest the campaign which the U.S. Government has started against the use of chemical preservatives agree that the anti-ferments which are are being used at present are insidious poisons which retard digestion. The movement of the Government is justified, but at the same time we know that preservatives are a necessity in many cases, and we

may expect that the resources of chemistry will secure a successful solution of the problem.

We know that calcium and magnesium are no foreign substances to water, milk, beer, or any food substance, consequently their introduction in the form of peroxides cannot be harmful to our system. It is known that hydrogen peroxide has preserving qualities, and it is also known that this chemical in the state of formation, or that nascent oxygen produced from a peroxide, surpasses in efficiency the action of a hydrogen peroxide solution. It remains to find the proper method of applying the peroxide. That this method has to be somewhat different from the present methods is explained by the difference of the nature of the peroxides and of the group of existing preservatives. The latter are substances which prevent fermentation for a certain length of time, by checking the growth of micro-organisms and rendering the treated material immune. In doing so they also check fermentation in our system, when consumed. The peroxide preservative, on the other hand will destroy the cause of fermentation and putrefaction, and keep the treated substance in a sterilised state, provided provision is made to prevent renewed contamination. Yet the material will not be immune when consumed, and there will be nothing in it to produce an anti-digestive action.

Evidently a difficulty arises in that we have to deal with aerobic and anaerobic microbes and enzymes, the first being carriers of oxygen, and showing some resistance to active oxygen, the latter acting as a catalyser in decomposing the peroxide. Yet, the conditions are such, that they offer a clear way to overcome the difficulty. If a liquid containing ferments is treated with calcium peroxide and exposed to the air, fermentation can even be accelerated. However, if the same liquid is treated with calcium peroxide, with the exclusion of outside air, fermentation is prevented. In analogy with this, is the fact that platinum black in alcoholic liquid exposed to the air similarly produces acetic acid fermentation, whereas, without the presence of air, such action is not noticeable.

These facts are based on catalytic actions, one of which, for instance, is being utilised in the production of vinegar. Before going any further, let us find an illustration in the treatment of sweet cider. This, it is well-known, is a hard substance to preserve, that is, to keep from fermenting. Raw apple juice treated with calcium peroxide can be made to ferment sooner than it would under ordinary circumstances, and apparently larger amounts of peroxide only accelerate the fermentation. We have succeeded in preserving cider in the following manner:—

Three hundred and fifty c.c. raw juice, as it comes from the press, was treated with a mixture of 0·1 grm. 60 per cent. calcium peroxide and 0·2 grm. of 15 per cent. magnesium peroxide. The liquid was kept in a bottle, hermetically sealed immediately after the addition of the peroxides, and shaken through. The first effect is a brownish coloration of the cider, which, however, begins to fade after two weeks, and after another couple of weeks the impurities begin to settle and the original colour, somewhat brighter, is restored. No fermentation took place, after nearly four months.

Why, then, does oxygen prevent fermentation and apparently destroy the cause of it when air is excluded, yet assist the process when in contact with air? In order to find our way through this apparent contradiction we have to consider the following principles:—

Among the substances of living cells which are present in vegetables, there are two groups which have great affinity for oxygen, and which are of the utmost importance in certain processes of oxidation occurring in plant life. These are the oxydase and the catalase or superoxydase. The first has the property to bind oxygen, and the second (according to Loew) is an oxydase which acts on peroxides or their hydrates in such a manner as to liberate their oxygen in a molecular state. They transfer the molecular oxygen to the oxydase, which again partly binds and partly transfers it to other bodies producing products of oxidation, an action which is performed similar to the action of peroxides. In doing so they either regenerate themselves or become used up.

Evidently, nature has placed these products in vegetables to support the living cell, that is, to produce intramolecular respiration, as well as to play the roll of a protector. On the other hand, the molecular oxygen which they store up is just what is necessary to assist the function of the germs of fermentation. Therefore, an excess of oxygen produced by catalase of the peroxide will pave the way for these germs and accelerate fermentation.

This latter process, however, will not occur at the start. It will only begin when the functions of oxydase have been accomplished in such a way as to allow the presence of free molecular oxygen. The prime function of oxydase is to create oxidation of the near-by products; and, as oxygen always attacks the lowest cell life first, it will be a germicidal action. In that, again, it will assist the peroxide action. If, therefore, a fermentable liquid is kept closed, with exclusion of air, it is well to assume that the energy of both the peroxide or peroxide hydrate, which has not been affected by the catalase and the oxydase, will be concentrated upon a destructive action on germs. Several authors have found that oxygen in an active state has the power to destroy germs of fermentation and enzymes in a diffused state. As under the given condition the germs of fermentation are in a highly diffused state, it will be understood why a liquid under such condition will not ferment. There will be a fight, in which the germs can only gain by multitude drawn from the air.

This very short outline is only given in order to show the way in which in our opinion, food chemistry has to go, in order to utilise this most convenient and, no doubt, only justifiable means of sterilisation and preservation—oxygen.

This part of the chemistry of oxygen, which is the main part, because it concerns animal and vegetable life, is still in its infancy. Further light will be thrown on it by the study of the character and functions of oxydase and catalase. We refer to Bach and Chodat (Compt. rend, 124, 951) and to the interesting report by Oscar Loew on Catalase (U.S. Dept. of Agric., Rpt., No. 68), and to his work, "Die Chemische Energie der lebenden Zelle," München, 1899.

The aforesaid also suggests that peroxides can be used for the ageing of alcoholic liquors, and for their purification, processes which, as Pasteur has already found, are nothing but slow processes of oxidation.

It will also be understood that peroxides, when used in a certain manner, are valuable reagents in the production of alcoholic and acetic acid fermentation, in assisting the action of saccharomycetes and mycoderni.

Finally, in considering the oxidation of alcohol to aldehyde, or acetic acid, of fusel oils to valeranic acid and butyric acid, and the subsequent formation of esters with alcohol, or salts with calcium, magnesium or bone black, it will be understood that peroxides can be used as reagents in the rectification and ageing of spirits. We refer to the interesting demonstration of Fitzgerald, of Niagara Falls, at the spring meeting, 1905, of the American Chemical Society in Buffalo, showing the elimination of fusel oils by means of calcium peroxide.

Application of magnesium peroxide.—Everything that has been said regarding the application of calcium peroxide is more or less also applicable to magnesium peroxide, with the difference that we have to reckon on one-third less available oxygen, but that, on the other hand, we have here a basic radical which, in many instances, will be preferable to calcium. According to the proportion in which magnesium salts form constituents of our food they come next to calcium salts, but according to their harmlessness, or, rather, beneficial physiological properties, they stand first.

On account of its very mild alkilinity, its non-astringency, and its beneficial action upon the digestive duct, this peroxide deserves to be recognised as, perhaps, the best suitable oxidising agent to be taken internally. Its main value consists in the pronounced property of promoting metabolism and in its indisputable qualification as an internal disinfectant. It is a mild antacid.

In our opinion, magnesium peroxide is the ideal means for sterilising drinking water, as no other re-agent, except calcium peroxide, comes near to it as regards both harmlessness and convenience in handling. In referring to this, we have not in mind sterilisation on a large scale,

referred to in the above-mentioned paper for the American Electrochemical Society at the meeting in Bethlehem, where the use of calcium peroxide was proposed; we contemplate the urgent demand of the soldier in the field, the workman in tropical countries, and, sometimes, the citizen in regions where the water is known to be contaminated with typhoid bacilli, the demand for a simple and convenient means to render the drinking water instantaneously free from pathogenic germs. This, in our opinion, is accomplished by a simple tablet, similar, for instance, to effervescent lithia tablets but, in our case, being an effervescent magnesium tablet, consisting of magnesium peroxide and citric acid. This preparation in itself would be harmless, and the minutely small quantities in which it would be used, unobjectionable. Its efficiency is shown in the following tests by W. H. Park, of the New York Health Department. They were made with 28 per cent. of magnesium peroxide partly in the form of tablets mixed with tartaric acid and partly with the powder alone. The tablets consisted of 0·10 grms. of peroxide, and an equivalent of tartaric acid. Dr. Park found that two tablets killed 2,250,000 typhoid bacilli in 150 c.c. of distilled water in one minute. One tablet killed 2,250,000 typhoid bacilli in 150 c.c. of distilled water in 30 minutes. Half a tablet killed 2,250,000 typhoid bacilli in 150 c.c. distilled water in 24 hours.

To orange juice containing 2,160 bacteria per c.c., was added enough typhoid culture to make 4,380 bacteria per c.c. Magnesium peroxide was then added in the proportions of 2 grms., 1 grm., and ½ grm. to the litre respectively. One c.c., of each of these mixtures was plated in agar at the end of five and 30 minutes.

Magnesium peroxide added.	5 min.	30 min.
2 grms.	4 col.	2 col.
1 grm.	0 col.	15 col.
½ grm.	29 col.	49 col.

The agar plate and broth culture made from the mixture of orange juice + typhoid + 1 grm. magnesium peroxide at the end of 24 hours, were both sterile.

The use of strontium peroxide.—Very little can be said about the application of strontium peroxide. No doubt it will be placed among the useful oxidising agents, on account of its specific chemical and physiological properties. Strontium peroxide has one important property, *viz.*, its partial dissociability in water without the aid of acids, a property in which it stands alone among the rest of alkaline earth and allied peroxides. For this reason, for instance, it could be recommended as an ingredient for a dentrifice. Saliva being slightly alkaline in reaction, a peroxide which needs an acid reaction would be ineffective.

G. W. Morse of Jersey City, recommends the use of barium peroxide for such purpose, and apparently overlooks the fact that barium salts are not admissible in therapeutics, on account of their poisonous nature.

We cannot close this paper without referring to the sterilisation of milk. Prof. Behring, and with him the majority of authorities, declare against the use of pasteurised milk for infant feeding, as by this process the proteids of milk undergo changes which render it less digestible; and Prof. Behring, surprisingly, recommends the use of formaldehyde. His proposal finds very little approval from authorities—though more among milk dealers—and things remain unchanged; now, as before, it is known that a great percentage of infant mortality is due either to organically contaminated milk, or to milk ill-treated by chemicals, or pasteurisation. As this problem is a very delicate one, we would not touch upon it if we had not the strong belief that some benefit will result from our proposition. Hydrogen peroxide, now-a-days, is known to be capable of preserving milk to an extent, but it is not used, probably because the ordinary commercial preparation is not appropriate, and the C.P preparation, which claims to be free from acid, is too expensive and inconvenient to handle.

C. G. L. Budde, of Copenhagen, in his patented process for the sterilisation of milk by means of hydrogen peroxide, claims that by his method the constituents of milk are neither chemically nor physically changed. H. C. Sherman, A. W. Hann and A. J. Mettler, in their report on "Comparative Experiments Upon Chemical Preservatives in Milk" (J. Amer. Chem. Soc., Sept. 1905, p. 1060) added the peroxide in the proportions of 1 to 1000, 1 to 5000 and 1 to 20,000, and obtained favourable results.

If calcium peroxide were added in the proportion of 1 to 10,000, it would represent the same amount of active oxygen as is yielded by hydrogen peroxide in the proportion of 1 to 1,000. We would, however, recommend a larger amount of calcium peroxide than 1 to 10,000, as this chemical does not at once bring its total amount of available oxygen into action, as it is the case with hydrogen peroxide, but it slowly decomposes. In that reserve, the property of not being exhausted within 24 hours, as A. J. Mettler has found, lies one advantage. The rapid disappearance of hydrogen peroxide in milk, which this author has found, is probably due to the action of catalase, an action, however, which, according to the results obtained, has not been detrimental.

Another advantage is, that the alkaline earth radical of calcium peroxide will assist in neutralising lactic acid, and its alkaline earth radical is the main factor among the inorganic constituents of milk. Calcium in milk is combined with the two forms of casein. It is combined with phosphoric acid and with organic acids. Furthermore, it is known that casein, which, according to Courrant, is an acid, is stable in the presence of certain alkaline bodies, among which is lime. There is present a certain amount of free lactic acid in fresh milk, which decomposes the calcium peroxide, resulting in the formation of calcium lactate and active oxygen. The incorporation has to be done by stirring, and closed containers will have to be used. Besides these chemical facts, a physiological feature deserves attention. Lime water is given to infants to counteract the abnormal intestinal fermentation produced by bottled milk. The probabilities are that milk treated with calcium peroxide will to an extent, bear in itself, the prevention of abnormal fermentation.

From the aforesaid it is right to assume that calcium peroxide added to milk would be there not as a foreign substance, but would be assimilated, only leaving behind the beneficial bactericidal effects of active oxygen. Our statement of these facts is made in the form of a suggestion to those interested in the important problem of milk sterilisation and preservation, the final solution we feel belongs to the fields of the physiologist and bacteriologist.

Sydney Section.

THE ANALYSES OF SOME NEW ZEALAND COALS.

BY A. M. WRIGHT.

(This J., Dec. 15, 1905, pages 1213—1214.)

ERRATUM.

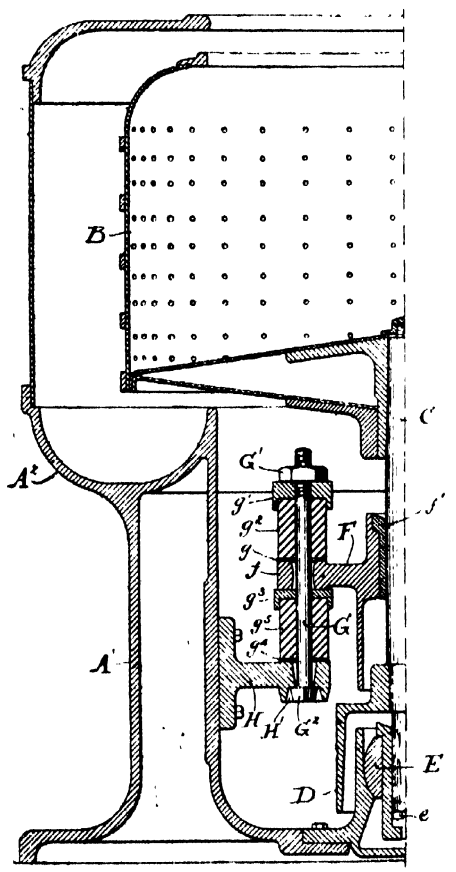
Journal and Patent Literature.

I.—PLANT, APPARATUS & MACHINERY.



(*Continued from page 257.*)

ENGLISH PATENTS.

Temperature; Apparatus for the interchange of ——. H. Kayser, Hamburg. Eng. Pat. 4148, Feb. 28, 1905.

"THE subject of the invention" is stated to be, "a process and an apparatus by means of which hot substances of a lower temperature can be brought to a higher temperature," and the following is given as an example.—The vapour of water formed in the space above a solution of sodium hydroxide has only a temperature of 100° C., whilst the solution has a temperature of 200° C. A serpentine coil of pipe in this solution serves to convey its heat to the vapour where there is a similar coil. The vapour is heated by the coil and the heat absorbed by the vapour is transferred to the solution.—W. H. C.

Extractors; Impts. in centrifugal ——. G. Binder, Philadelphia, Pa., U.S.A. Eng. Pat. 4271, March 1, 1905. Under Int. Conv., March 25, 1904.

THE basket, B, surrounded by the fixed "curb," A^2, is carried by the spindle, C, which is supported at the bottom only, by the ball-bearings, E,e. It is consequently free to oscillate, the oscillations being limited by the "spider," F, which holds the spindle, C, by the bushing, f^1, and is provided with three equi-spaced radial arms, *f*, each of which is attached by the washers, *g*, g^1, g^3, g^4, the springs, g^2, and g^5, and the nut, G^1, to a spindle, G. The lower end, G^2, of the spindle passes through the hole, H^1, in the bracket, H, supported on the standard, A^1, as shown in the figure and, owing to the construction of the opening, H^1, it has a certain freedom of movement, limited by the tension of the springs, g^2, and g^5. The spindle, C, is driven by a belt which passes round the pulley, D, and the washers, g^1, and g^3, are made to enclose the upper parts of the springs, g^2, and g^5, to protect the latter from drops of oil.—W. H. C.

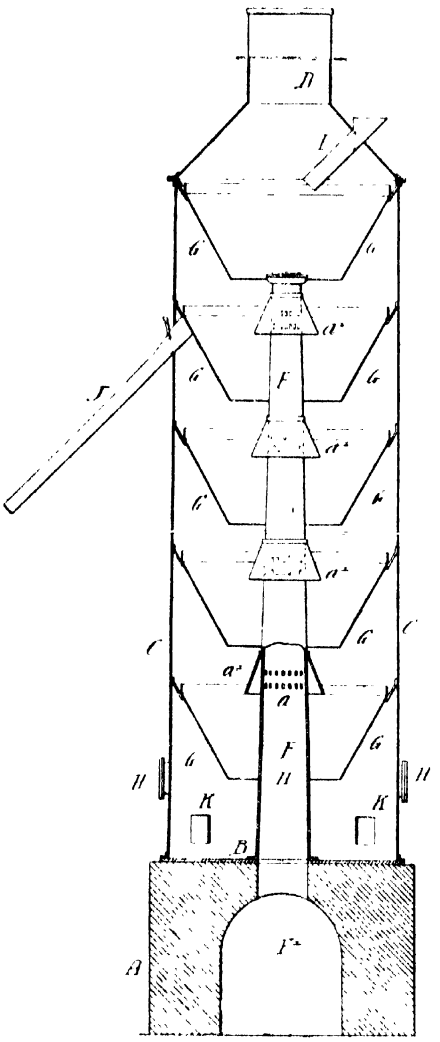
Fumes escaping from furnaces; Recovery of valuable constituents from ——. G. A. Mower, London. Eng. Pat. 6185, March 23, 1905.

A HOOD is arranged above the furnace door or other aperture from which, by means of a pipe, the fumes are conveyed to a washing tower constructed with baffles, over which water is allowed to flow so as to wash down the valuable constituents of the fumes.—J. H. C.

Distilling and condensing apparatus; Impts. in ——. E. Brown, London. Eng. Pat. 6916, April 1, 1905.

THE condenser attached to the still consists of a truncated cone with an open top, surrounded by a truncated cone with a domed top and an internal gutter (provided with a discharge pipe) round the base. Surrounding the outer cone is a chamber into which the cooling liquid is admitted through a pipe situated on about the same level as the internal gutter. The relative arrangement of the two cones is such as to prevent the steam from impinging on the collecting gutter.—C. S.

Evaporating liquids and concentrating the solids in the same; Means for —— also applicable as a smoke washer. A. B. Lennox, Newcastle-on-Tyne, and T. Mackenzie, Glasgow. Eng. Pat. 7961, April 14, 1905. (See also Eng. Pat. 13,227 of 1904; this J., 1905, 811.)



A SERIES of separate evaporating chambers are arranged in the flue leading from a boiler or furnace to a chimney. In the roof of each chamber is a spraying device, through which the liquid to be evaporated is sprayed and is evaporated by the gases traversing the flue. Any of the liquid that is not so evaporated falls to the bottom of the flue and drains into a tank, whence it is returned in a heated state, to the evaporating chambers through the spraying devices. Baffles may be provided in the chambers, to cause the flue gases to take a sinuous course. When the device is used as a smoke washer, the dirty liquid is run away into the sewer, or removed in any other way.—C. S.

Evaporating apparatus; Impts. in ——. G. R. Ray, Manistee, Michigan, U.S.A. Eng. Pat. 24,186, Nov. 23, 1905.

THE temperature in the steam-chamber of a vacuum evaporator has been found to vary in different parts of the apparatus. To overcome this defect the steam is first passed through a mixing chamber provided with baffle-plates, where it is reduced in temperature and thoroughly mixed, so that it enters the evaporator at an uniform temperature.—W. H. C.

Coolers for powdered, or granular, material. G. W. Johnson, London. From C. A. Matcham, Allentown, Pa., U.S.A. Eng. Pat. 8814, April 26, 1905.

A VERTICAL, cylindrical metal casing, C, is mounted on the base, A, and has a stack, D, at the top. The material to be cooled is fed through the valved shoot, I, and falls into the uppermost of a series of superposed deflectors, G, any surplus being carried off by the valved shoot, J.

The material passes down from deflector to deflector, and is finally removed through the doors, K, after being cooled by a current of air which enters through the tunnel, F¹. The air passes up the central tube, F, which is closed at the top, out of the openings, *a*, protected by the hoods, a^1, and over the material in the deflectors, G. The latter are of less diameter than the casing, C, so as to allow the air to pass up between their outer edges and the wall of the casing to the stack. A natural draught is thus caused through the apparatus without the use of a fan. By passing heated air into the casing through the openings, H, the apparatus can be used as a drier or a kiln.—W. H. C.

Temperature of heated articles and of furnaces, crucibles and the like; Method of and appliances for ascertaining the ——. Rudge-Whitworth, Ltd., and J. V. Pugh, Coventry, and H. L. Heathcote, Birmingham. Eng. Pat. 10,617, May 20, 1905.

The object, the temperature of which is to be ascertained, is viewed through one or more colour-screens, so constructed that at certain definite or approximate temperatures the object appears non-luminous. The screens may be either transparent cells containing a coloured solution which has definite light-absorbing properties, or the colouring matter may be emulsified with gelatin and spread on glass plates, or thin plates of coloured gelatin may be used.—W. H. C.

Separating apparatus; Centrifugal ——. Aktiebolaget Separator, Stockholm. Eng. Pat. 10,875, May 24, 1905. Under Int. Conv., May 27, 1904.

See Fr. Pat. 354,416 of 1905; this J., 1905, 1162.—T. F. B.

Centrifugal separators; Impts. in ——. A. F. Spooner, London. From Aktiebolaget Separator, Stockholm. Eng. Pat. 19,277, Sept. 23, 1905.

The combination claimed is that of a shallow, self-balancing bowl with a liner consisting of involute plates, set close together and capable of turning on a ring or the like, in order to secure a high skimming capacity.—C. S.

Drying kilns; Impts. in ——. Soc. de Constructions Mécaniques D'Alais, Alais, France. Eng. Pat. 16,294, Aug. 10, 1905. Under Int. Conv., Dec. 1, 1904.

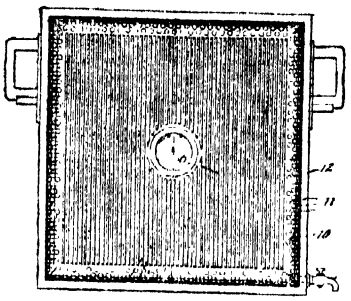
A horizontal cylinder, mounted so that it can be rotated within a brick casing, has its interior surface provided with longitudinal plates arranged round the periphery, and forwardly projecting blades spaced in the form of a spiral, to move forward and mix the material under treatment. The latter is fed in continuously at one end, through a valve-controlled shoot, and is discharged from the other end. The hot gases from a furnace situated below the inlet end of the cylinder are caused to take a spiral path around the outside of the shell by baffles which project from the brick casing. The gases then return through the cylinder over the material to be dried, and are exhausted by a fan, along with the vapours given off, from the feed end.—W. H. C.

Kilns; Method of and means for utilising the heat in tunnel ——. G. Gröndal, Djursholm, Sweden. Eng. Pat. 17,947, Sept. 5, 1905.

To utilise the heat in intermittent tunnel kilns, air is introduced into the cooling compartment in larger quantity than is needed for the combustion of the fuel used to generate heat for the baking compartment, the excess of heated air so obtained being then conducted into the preliminary heating compartment through a suitably controlled conduit situated underneath the trucks in the cooling compartment and passing by the baking compartment.—C. S.

Ovens or stoves for heating, drying, baking, enamelling, and other purposes; Impts. in ——. A. W. Naylor, Halton. Eng. Pat. 18,545, Sept. 14, 1905.

A portable stove or oven heated by gas is constructed with the side plates fitting into specially formed grooves in the end plates. At the top of the oven is a perforated ventilating flue, the inlets to which may be closed by a sliding valve, to regulate the ventilation of the oven.—W. H. C.



Drying process; An improved —— and apparatus therefor. A. H. Messinger and V. Popper, Vienna. Eng. Pat. 25,871, Dec. 12, 1905.

The claim relates to "stage or tier-trough drying apparatus" in which the troughs are of equal size. The two upper troughs are fed simultaneously with fresh material which is discharged when partly dried into a lower trough, common to both, the object being to avoid the loss of drying effect due to the shrinkage of the material. Claim is also made for an adjustable slide which divides the feeding shoot so that the amount of material fed to the upper troughs may be regulated, and for adjustable flaps or dampers to control the admission of heated air to the apparatus.—W. H. C.

United States Patents.

Filter-plate. W. B. Allbright, Chicago, Ill. U.S. Pat. 813,395, Feb. 27, 1906.

The claim is for a filter-plate constructed with a ribbed

centre, 6, and an outstanding rim, 12, the surface of the face, 10, between, 6, and, 12, being studded with "round knobs or buttons," 11.—W. H. C.

Mixing apparatus for dry materials. G. Raps, Stolberg, Germany. U.S. Pat. 814,233, March 6, 1906.

THE mixer consists of a tapering drum mounted horizontally, the larger end being entirely closed, whilst the smaller end is fitted with feed and discharge openings formed by means of a flange and ring, the latter spaced from the walls of the drum. A number of spiral blades are arranged inside the drum, and the whole is rotated by suitable means.—C. S.

FRENCH PATENTS.

Drying air for ventilating and general purposes; Process and apparatus for ——. C. J. S. Lambert. Fr. Pat. 359,023, Jan. 9, 1905.

THE air is first passed through a cooling chamber of any one of the usual types for drying air by contact with cooled surfaces, the point of the invention being that the air is not cooled below a point just above that at which the deposited moisture freezes. It is then passed through a second vessel where it is brought into contact with a cooled solution of calcium chloride. From the combination of these two processes certain advantages are claimed to result. In the first apparatus, as no snow or ice is formed, the cooling surfaces retain their efficiency, and there is no necessity to interrupt the process to thaw any deposited ice. In the second apparatus, as the greater part of the water has been removed by cooling, a relatively small quantity of calcium chloride solution is required to complete the desiccation.—W. H. C.

Concentrating apparatus [for muddy liquids]. E. Vial. Fr. Pat. 358,998, Oct. 30, 1905.

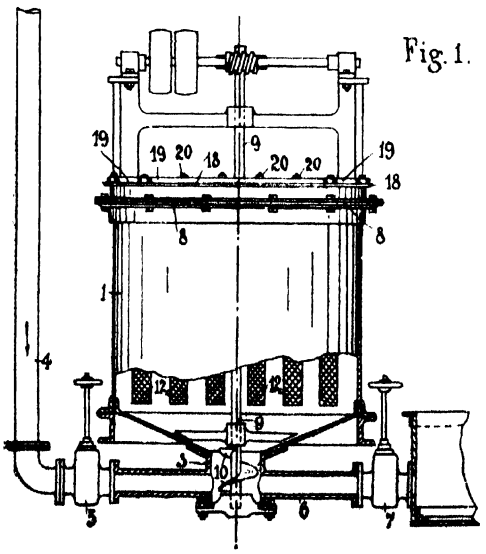


Fig. 1.

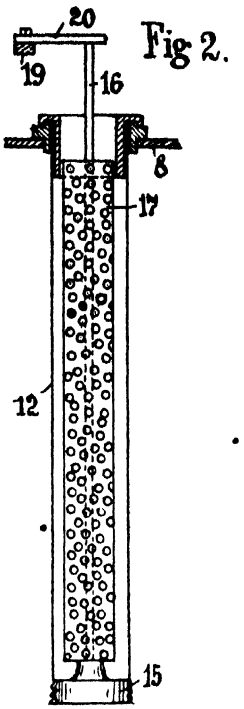

Fig. 2.

THE muddy liquid enters the apparatus from a reservoir, placed at a higher level, through the pipe, 4, and the valve, 5, and passes through the opening, 3, into the cylinder, 1. This latter has a cover, 8, provided with a rim, 18, the cover being perforated with round holes through which a number of filter tubes, 12, hang down into the cylinder. The liquid rises through the tubes by its own pressure, and collects in the open tray formed by the rim, 18, from which it is run off to a reservoir, whilst the solid matter in suspension collects in the lower part of the cylinder, 1, and on the exterior of the tubes, 12. When the liquid is sufficiently concentrated, the supply is shut off by closing the valve, 5, and the concentrated liquid is run out by the pipe, 6, and the valve, 7, which is opened only during the discharge. An agitator, 10, worked by the rod, 9, is used to assist in discharging the contents of the vessel, 1.

The filter-tube is shown on a larger scale in Fig. 2. It consists of a cylinder of porous material, 12, closed at the bottom by the plate, 15, and prevented from collapsing by the inner perforated cylinder, 17. The tubes are kept in position by the bent rods, 16, 20, attached to the bottom of the tubes and fastened to bars, 19, which are placed across the rim, 18. When it is desired to wash the filters, the rod, 20, is loosened and the tubes are plunged alternately up and down in the vessel, 1, whereby the deposit is washed off by the concentrated liquid.—W. H. C.

Gases; Process of compressing ——. G. Meyersberg. Fr. Pat. 359,003, Oct. 30, 1905.

THE claim is for a process of compressing air or gases which consists in passing the gas through a series of vessels in which it is heated. The heat energy is stated to be converted into kinetic energy which is applied to cause the gas to leave the apparatus at a higher pressure than that at which it enters.—W. H. C.

Machines for aspirating air laden with earthy or dusty matter; System of filtration for protecting ——. G. Todeschini. Fr. Pat. 359,054, Nov. 2, 1905. Under Int. Conv., Nov. 3, 1904.

IN order to protect the moving parts of the air-pump

from the abrasive action of the dusty matter in the air, the latter is drawn through a washer. The washer consists of a vessel, partly filled with water. The air enters by a pipe opening below the surface of the liquid, at one end of the vessel, and passes to the air-pump through another pipe, above the surface of the liquid at the other end. As the air thus traverses the whole length of the vessel, any bubbles formed will be broken before they reach the outlet. To diminish the size of the bubbles, the liquid is rendered milky, dense and soapy by the addition of calcium carbonate, soft soap and "creoline."
—W. H. C.

GERMAN PATENT.

Heat-insulating composition for steam-pipes and the like. V. Holczabek. Ger. Pat. 165,342, Feb. 20, 1904.

THE seed-pods of the cotton plant are mixed with a binding agent and incorporated with other insulating substances, such as kieselguhr, asbestos, tar and asphaltum. For example, 80 kilos. of the cotton-seed pods are mixed with about 20 litres of water, about 15 kilos. of a binding agent, such as clay, are gradually added, and then 12—20 kilos. of kieselguhr.—A. S.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 258.)

Cyanogen in coal gas. A. Samtleben. J. Gasbeleucht., 1906, **49**, 205—209.

THE author's experiments were carried out at the Bernburg gas works where no cyanogen extractor is in use. The gas at the inlet and outlet of the purifier boxes contained, on the average, 213·4 and 18·0 grms. of hydrogen cyanide per 100 cb. m. respectively. The average test of the town gas was 16·4 grms. of hydrogen cyanide per 100 cb. m., the water in the holder containing 13·5 grms. per 1 cb. m., which acted on the paint of the holder causing blue stains. The composition of the purifying material after one year's working was: Prussian blue, 3·65 per cent.; thiocyanate, 0·27 per cent.; sulphur, 35·51 per cent.; sulphuric acid, 1·35 per cent.; ammonia, 0·59 per cent.; water, 8·32 per cent. Calculated from the amount of hydrogen cyanide removed from the gas, the purifying material should have contained 6·3 per cent. of Prussian blue. The difference is attributed to the action of oxygen, 2 per cent. of air having been admixed with the gas.

The rate of formation of cyanogen in the retort during one carbonising period was ascertained with Zwickau (Saxon) and Yorkshire silkstone coal at temperatures of about 950° and 1050° C. Two curve-diagrams are given showing grms. of hydrogen cyanide per 100 cb.m. of gas as ordinates with hours of carbonisation as abscissæ. The maximum was reached in the different cases somewhere after the second hour.—R. L.

Carbon monoxide; Difficulties in the determination of —— in gaseous mixtures. A. Gautier and Clausmann. XXIII., page 337.

Fuel trade of France. Mining World, March 10, 1906.

IMPORTS in 1905 were somewhat less than in 1904, but exports showed an increase. Business has been transacted principally with Great Britain and Belgium, although Germany has sent more coke to France than any other country.

The foreign trade in the past year was as follows in metric tons:—

	Imports	Exports.
Coal	10,513,920	1,658,680
Coke	1,632,710	242,040
Briquettes	399,390	88,940
Total	12,546,020	1,989,660

Changes in 1905 from 1904 were:—Coal imports, decrease of 370,948 tons; exports, increase, 538,533 tons. Coke, imports, decrease, 23,654 tons; exports, increase, 81,450 tons. Briquettes, imports, decrease, 128,717 tons; exports, increase, 22,152 tons. Imports, as a whole, show a falling off from 1904 of 523,319 tons; exports an increase of 642,138 tons; a balance in favour of exports of 118,819 tons.

Of the imports in 1905 Great Britain furnished 5,759,010 tons of coal (5,797,316 tons in 1904); Belgium, 3,460,430 tons of coal (3,855,547 tons in 1904), and 500,690 tons of coke (527,948 tons in 1904); Germany, 850,490 tons of coal (888,455 tons in 1904), and 1,114,850 tons of coke (1,112,650 tons in 1904); while the remainder was contributed by various other countries. Of the exports Belgium received 1,148,000 tons of coal (663,700 tons in 1904), and 69,550 tons of coke (44,824 tons in 1904); Switzerland, 210,050 tons of coal (168,524 tons in 1904), and 44,070 tons of coke (36,562 tons in 1904); French and foreign vessels, 132,940 tons of coal (137,033 tons in 1904), and 32,470 tons of briquettes (50,531 tons in 1904); whilst the balance was for various countries. [T.R.]

ENGLISH PATENTS.

Peat fuel; Manufacture of ——. Central Torfkohlen Ges.m.b.H., Berlin. Eng. Pat. 27,397, Dec. 15, 1904. Under Int. Conv., Dec. 17, 1903.

SEE Fr. Pat. 349,139 of 1904; this J., 1905, 612.—T. F. B.

Fuel, Artificial ——. P. Grayson, London. Eng. Pat. 10,866, May 24, 1905.

COAL (about 2 lb.) reduced to the form of impalpable dust is mixed thoroughly with plaster of Paris (about 3 oz.) or cement, or both; from 6 to 18 oz. of water are added, and the mixture is compressed into any desired shape. Other binding and combustible materials may also be incorporated.—H. B.

Gas furnaces for charcoal and like kilns. J. Buchanan, Liverpool. Eng. Pat. 4921, March 9, 1905.

THE claim is for a furnace for heating animal charcoal kilns in which the gas passes from a gas chamber to a mixing chamber, provided with air-inlets spaced alternately with the inlets for gas and the outlets through which the mixture escapes to a combustion chamber. To avoid long tongues of flame and to get a better distribution of the heat, perforated blocks of metal or of refractory material are placed over the gas outlets, or the whole of the interior of the heating chamber may be packed with such blocks or with bricks. The lower heated parts of the kiln are surrounded by a casing, and the air is circulated through the chamber so formed, to pre-heat it and to cool the contents of the kiln. The air may be further heated before it reaches the mixing chamber, by passing it through flues formed in the brickwork of the combustion chamber, and the heating effect of the gaseous fuel may be increased by injecting compressed air, with or without oil spray, into the mixing chamber.—W. H. C.

Gas; Furnaces and retorts for the manufacture of ——. A. Rummens, Kockelberg, Belgium. Eng. Pat. 9151, May 1, 1905.

SEE Fr. Pat. 353,865 of 1905; this J., 1905, 1057.—T. F. B.

Kilns for generation of gas, roasting and the like; Rotary ——. S. E. Sieurin, Hoganas, Sweden. Eng. Pat. 15,838, Aug. 2, 1905.

SEE Fr. Pat. 356,615 of 1905; this J., 1906, 11.—T. F. B.

Retorts for the destructive distillation of coal; Vertical ——. H. W. Woodall, Wimborne, and A. McD. Duckham, Upper Parkstone, Dorset. Eng. Pat. 21,447, Oct. 21, 1905.

THE claim relates to the method of removing the coke from vertical retorts (described in Eng. Pat. 16,497 of 1903; this J., 1904, 744), and consists in arranging a horizontal plate underneath the lower end of each retort, but above the level of the water-seal. The coke rests on this plate instead of in the water of the seal, and is not damaged by too long contact with the water. A water-cooled pusher or rake, operated from without the casing, pushes the coke, at intervals, from the plates on to a belt conveyor which carries it away through the water-

seal. By regulating the rate at which the pusher works, the feed of coal into the retorts, and the degree of carbonisation is adjusted.—W. H. C.

Gas for illuminating and heating purposes, and apparatus therefor. A. H. Arzt and S. Baron, London. Eng. Pat. 24,242, Nov. 9, 1904.

AIR is blown simultaneously into a gas-holder and into a carburetter, encountering, in the latter, a finely divided supply of liquid hydrocarbon which trickles down through a mass of porous material capable of yielding silicon hydride. The porous material may be made by mixing powdered magnesia, silica, and a saturated solution of sodium chloride into a stiff paste, moulding, drying and baking the product, and impregnating it with triethyl silico-formate, $SiH(OC_2H_5)_3$. This material is said to evolve silicon hydride, SiH_4, which is immediately decomposed, the silicon being oxidised whilst the hydrogen unites, in the cold state, with the vapour in the carburetter, the gas produced being conducted into the gas-holder and mixed with the air therein.—H. B.

Combustion gases under pressure; Apparatus for producing —— for use as motive power for driving turbines and the like, and means in combination therewith for producing a liquid jet. A. Vogt, London. Eng. Pat. 26,178, Dec. 1, 1904.

AIR and combustible gas (or sprayed liquid fuel) are admitted continuously under pressure into a strong steel cylinder, wherein they burn, with the production of hot gases under high pressure, which are led out at high velocity through a discharge nozzle at the end of the cylinder to the apparatus in which the motive power is to be developed. Within the outer cylinder is a series of concentric cylindrical casings, of thin sheet nickel or the like, one within the other. The compressed air supply is obliged to pass consecutively up and down the annular spaces between the cylindrical casings, before it encounters the gas supply on entering the innermost casing. In this way the air is preheated, and loss of heat by radiation is minimised. The discharge nozzle may be surrounded by another, supplied with liquid, whereby, owing to the injector action, a jet of liquid at high velocity may be formed.—H. B.

Suction-Gas producer plant. C. Whitfield, Kettering. Eng. Pat. 4917, March 9, 1905.

THE gas-outlet pipe from a producer passes vertically downwards, and opens into the top of an enclosed tank let into the ground; the scrubber rises vertically above the same tank, which is long enough to extend beneath the open ends of both the pipe and the scrubber, and leave a portion open at the top to the atmosphere. A flange, depending from the top of the tank into the water therein, seals off the open part from that through which the gas flows on its way from the pipe to the foot of the scrubber, and permits the water level to rise and fall, in the part below the pipe and scrubber, at each suction stroke. The vertical portion of the gas-outlet pipe is grooved spirally on its exterior and is enclosed in an open-ended concentric sleeve from which a branch pipe leads to the generating chamber of the producer; water is allowed to flow down the spiral grooves and is vaporised by the heat derived from the out-flowing gas; and the mixture of air and steam is aspirated, at each stroke, into the producer from the annular space between the grooved pipe and the sleeve.—H. B.

Gas producers; Impts. in ——. Tangyes, Ltd., Soho, Staffs., and J. Robson, jun., Handsworth, Staffs. Eng. Pat. 8534, April 20, 1905.

THE gas producer, which is designed for use with bituminous coal, and more particularly as a suction producer, is provided at the lower part of the combustion chamber with an annular water-vaporising chamber, through which the air supply is led before passing to the upper part of the combustion chamber. Whilst gas is being produced, the air and vapour are led only in a downward direction through the fuel; hence the tarry matters given off by the fresh fuel, which is charged into the producer from above, have to pass downwards through the incandescent zone, becoming completely gasified. A blower and suitably valved pipes are provided, whereby, in starting the combustion, air can be blown either upwards or downwards through the fuel. If an additional supply of steam is required, the hot gases are led through a tubular interchanger containing water, over which an additional air current is drawn.—H. B.

Gas producers; Construction and method of operation of ——. H. Lane, Manchester. Eng. Pat. 10,496, May 19, 1905.

THE producer is of the intermittent type, and during the steaming period the steam is introduced above and below the fuel so as to traverse the same, partly in an upward direction and partly downward. The gas is collected in an annular conduit, in the thickness of the brickwork shell of the producer, about midway in the height of the column of fuel, and communicating with the generating chamber by radial apertures or perforations. —C. S.

Electric glow lamps; Process of making a metallic connection between the light-emitting bodies and the supply conductors of ——. H. Kuzel, Baden, Austria. Eng. Pat. 15,462, July 27, 1905.

A METALLIC connection, between the light-emitting body and its supply conductors, is made by applying to the joints a metal of high melting point whilst such metal is in a colloidal or pasty condition, as described in Eng. Pat. 28,154 of 1904 (this J., 1906, 115), drying the pasty substance, and heating the joints gradually to a white heat in a neutral atmosphere.—H. B.

UNITED STATES PATENTS.

Gas-producers; Process of operating ——. B. E. Eldred, Bronxville, N.Y., Assignor to Combustion Utilities Co., New York. U.S. Pat. 813,628, Feb. 27, 1906.

THE process of operating a gas producer consists in cooling, purifying and compressing products of combustion, and feeding these compressed gases, admixed with air, into the producer in the form of a high-pressure jet, through an unsealed passage way, containing a similar mixture, whereby the feed will respond to the pressure in the producer.—W. C. H.

Gas-producer. C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 813,629, Feb. 27, 1906.

THIS patent covers an arrangement of a gas making and using plant, which forms an almost closed system. The gas supplied by the producer is used in heating a furnace, and the products of combustion, low in carbon dioxide or containing an excess of oxygen, escape to the stack. The stack is tapped by a pipe through which a portion of the products of combustion are withdrawn. This pipe is surrounded by a casing, provided with an inlet for air, for the purpose of cooling the products of combustion in the pipe; and the air thus heated is used as the supporter of combustion in the furnace, the movement of the air being effected by a fan, on the pressure side of which an excess-outlet is arranged, *i.e.*, between the fan and the furnace. The products of combustion are drawn from the stack, through the cooling apparatus, and delivered to the gas producing zone of the producer by means of a fan. There is a valved air-inlet on the pipe on the suction side of the fan, by which air is mixed with the products of combustion introduced into the producer, and a valved waste-outlet on the pipe connecting the fan with the producer.—W. C. H.

Gas; Apparatus for producing ——. C. Ellis, White Plains, N.Y. U.S. Pat. 814,279, March 6, 1906.

THE gas-producing plant described comprises a fuel-burning furnace, provided with a chimney stack, from which hot products of combustion are drawn through a gas-washer, by means of a fan, and forced, when washed, into a producer, the pipe connections being also provided with means for admixing regulated amounts of air with the washed gases before entering the producer. (See also preceding abstract.)—W. C. H.

Gas; Process of generating ——. C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 814,001, Feb. 27, 1906.

In the generation of gas in a gas producer, an endothermic body consisting of mixed products of combustion from different sources, is supplied to the draught current, whereby the temperature of this endothermic body may be regulated to any desired degree. The mixture may consist of the products of combustion from a furnace treating ore and of those from a boiler furnace.—R. L.

Gas-producer. J. H. Swindell, Pittsburg, Pa. U.S. Pat. 814,249, March 6, 1906.

In the producer described, a combustion chamber, a cooler, a scrubber, and a purifier chamber are all included in the same casing, and suitably connected. The combustion chamber is provided with a water-seal ash-pit, and at the bottom of the cooler is a water-seal tar-receiving pan, which extends beyond the casing, to allow of the removal of tar, without interrupting the working of the apparatus. Air and steam are introduced into the space beneath the grate, the steam being supplied from a tank or boiler which surrounds a portion of the combustion chamber, and the air through a draught pipe, into which steam from the boiler is directed. The steam pipe is provided with a valve, and the draught-pipe with a damper, both of which are automatically controlled by the pressure of the gas issuing from the apparatus; the suction of the gas affects a diaphragm which is connected with a walking-beam connected with the valve and damper.—W. C. H.

FRENCH PATENTS.

Briquettes; Lignite or peat ——. C. F. M. Guirouvet. Fr. Pat. 350,424, Dec. 24, 1904.

Peat or lignite is distilled in a retort, and the residual coke is pulverised and incorporated with tar and a small quantity of saltpetre, the whole being compressed in moulds, then dried, and reheated in an oven until the liberation of fumes has ceased.—C. S.

Peat; Process for desiccating and preparing ——, *for utilisation as fuel or litter.* D. R. O'Sullivan-Beare. Fr. Pat. 358,699, Oct. 20, 1905.

After pressing out the greater part of the "free" water by mechanical means, the "latent" water in the peat is liberated by the application of heat in a suitable manner, so as to soften the fibre. The softened peat is next treated in a special filter-press, so as to break the fibres and express the contained water, the residue being put through a felting process and pressed into solid briquettes in suitable moulds.—C. S.

Combustible; Artificial ——, *and process for its manufacture.* A. Engle. Fr. Pat. 358,831, Oct. 24, 1905.

Night-soil and similar matters are mixed with quicklime, which absorbs water and also renders them inodorous. The resulting mass is mixed with twice its bulk of powdered coal and is made into a mass with tar or oil residues and briquetted.—W. H. C.

Coal and similar combustibles; Compound for assisting the combustion of ——, *and for preventing the clinkering and destruction of the fire-bars.* J. A. Fravel. Fr. Pat. 358,807, Oct. 24, 1905.

A solution of alkali nitrates, holding in suspension a small proportion of ferrous oxide, is sprinkled over the coal or other combustible before the latter is charged into the furnace, or it may be sprayed over the fire itself. The nitrates are decomposed by the heat and liberate oxygen which assists the combustion, whilst the bases present combine with any silica in the fuel to form an ash which does not produce clinker on the bars.—W. H. C.

Gaseous mixture; Apparatus for determining the proportions of a ——. P. de Bruyn, G.m.b.H. Fr. Pat. 358,515, Oct. 14, 1905.

The gas to be examined is admitted at the enclosed base of a chimney which surrounds another chimney, of much smaller diameter, in which a flame is burning. The diameter of the inner chimney diminishes towards the top, and a long flame is produced within it. The gas under examination partly enters the lower end of the inner chimney, thus furnishing the oxygen required by the flame, and partly flows up outside it, escaping at the top into the atmosphere. According as the gas contains less or more oxygen, the flame lengthens or shortens proportionately, and by observing the length of the flame by means of a scale behind it, the composition of the gas is determined.—H. B.

Water-gas; Device for introducing ——, *into coal-gas retorts.* J. E. Goldschmid. Fr. Pat. 358,562, Oct. 16, 1905. Under Int. Conv., Oct. 17, 1904.

The elbow pipe through which the water-gas is led into the gas retort is provided at the angle with a perforated plug and a lateral screw stopper so arranged that, by removing the plug or the stopper, access can readily be had to either limb of the elbow pipe.—H. B.

Gas generator in direct connection with a burner. L. Koester. Fr. Pat. 358,632, Oct. 18, 1905.

The generator chamber, containing the fuel, is placed in direct communication with the boiler or other apparatus to be heated, and streams of air are admitted both above and below the opening in the masonry through which the generator gas enters the combustion chamber of the apparatus in question, these air streams serving to keep the masonry cool by flowing over its outer surfaces before entering the combustion chamber.—H. B.

Contact material [for gas mixtures]; Support for——. Soc. Française d'Incandescence par le Gaz (Système Auer). Fr. Pat. 358,808, Oct. 24, 1905.

In the production of illuminating or heating gas by catalytic processes, notably in the reduction of carbon monoxide with hydrogen, the temperature of reaction may be considerably reduced and, incidentally, the catalytic power of the contact material strengthened, by employing a fibrous substance or filaments as support for the latter. For instance, fibrous asbestos may be impregnated with a solution of a salt of iron, nickel, cobalt or copper, which latter is then transformed into the oxide and subsequently reduced to the metal.—R. L.

Gaseous medium for carrying the vapours of volatile combustible liquids; Process for producing a non-oxidising ——. C. Martini and H. Huneke. Fr. Pat. 359,018, Oct. 31, 1905. Under Int. Conv., May 15, 1905.

A combustible gas, such as coal gas, is mixed with the quantity of air necessary for its complete combustion, and the mixture is burned continuously in a closed chamber, in the absence of air. The gaseous products of the combustion are led through a cooling device into a carburetter, containing gasolene or the like, for the production of carburetted gas. It is claimed that this non-oxidising vehicle for the combustible vapour is safer than air or the exhaust gases from gas engines, boiler furnaces, &c., whilst being cheaper than carbon dioxide. —H. B.

Electric incandescence lamps; Process of making luminous bodies for ——. H. Kuzel. Fr. Pat. 359,025, Jan. 9, 1905.

See Eng. Pat. 28,154 of 1904; this J., 1906, 115.—T.F.B.

Carbon filaments for incandescence lamps, and process for making the same. Cie. Franç. pour l'Exploitation des Procédés Thomson-Houston. Fr. Pat. 358,921, Sept. 5, 1905

See Eng. Pat. 6959A of 1904; this J., 1905, 721.—T.F.B.

Incandescence electric lamps with filaments of tungsten, molybdenum, or similar metals; Process of manufacturing ——. Siemens and Halske, A.-G. Fr. Pat. 359,010, Oct. 31, 1905. Under Int. Conv., Nov. 15, 1904.

See Eng. Pat. 23,098 of 1905; this J., 1906, 115.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 258.)

Petroleum products. U.S. Customs Decision, Jan. 10, 1906.

THE United States Circuit Court of Appeals, decided that the provision in paragraph 626 of the tariff, "that if there be imported into the United States crude petroleum or the products of crude petroleum produced in any country which imposes a duty on crude petroleum or its products exported from the United States, there shall in such cases be levied, paid and collected a duty upon said crude petroleum or its products so imported, equal to the duty imposed by such country," means that when crude petroleum is imported into the United States it shall pay whatever duty is laid upon it by the country where it is produced. Further, when any product of crude petroleum is so imported it shall pay the duty imposed upon such product by the country where such product is produced. If, however, the country making the product imposes no duty on similar products from the United States, the product shall have free entry into the United States even though the crude petroleum from which the product is made be produced by a country imposing a duty on the crude petroleum of the United States. Thus Russia and Germany each impose a duty on crude petroleum and its products imported from the United States, while Belgium does not. Hence paraffin oil manufactured in Germany from Russian petroleum is subject to the rates levied by Germany on American paraffin oil, while paraffin oil manufactured in Belgium from Russian petroleum is free of duty when imported into the United States. The Court further held by a majority-opinion that the provision of paragraph 633 for the free entry of paraffin does not operate to exclude it from the provision for products of crude petroleum as above given; also that the same provision includes the more valuable petroleum products, but not the less valuable ones, such as *paraffinum molle* composed of paraffin oil and ceresin, the latter of principal value. [T.R.] R. W. M.

UNITED STATES PATENTS.

Distilling wood and obtaining therefrom the different by-products; Apparatus for ——. W. W. and T. L. James, Rawles Springs, Miss. U.S. Pat. 813,302, Feb. 20, 1906.

A RECTANGULAR, box-shaped retort is mounted, by diagonally opposite corners, on standards of equal height, and is fitted with internal steam coils arranged along the vertical sides of the retort, so as to leave a central space for the charge of wood to be distilled. Steam supply and discharge pipes are provided, the latter containing a "puppet valve"; and charging and discharging doors are carried by the vertically opposite upper and lower corners of the retort.—C. S.

Coke Oven. G. Pierboni and P. Bufano, Connellsville, Pa. U.S. Pat. 814,621, March 6, 1906.

THE oven is of ovoid form and is provided with an arched roof, constructed of bricks of keystone form laid in tiers, the ends of each tier being closed with a horizontally tapered key brick, and the centre of the arch being closed with an approximately ovoid brick forming the vent of the oven. The oven is provided with a door or opening, the wall adjacent to the same being concaved or arched horizontally.—C. S

FRENCH PATENTS.

Coke ovens; Horizontal ——, *with gas circulating alternately in opposite directions.* W. Klönne. Fr. Pat. 358,624, Oct. 18, 1905.

TWO gas mains are provided at each end of the oven, to work alternately, each of them delivering the gas into one of two parallel, longitudinal channels, situated in juxtaposition underneath the sole of the series of flues in each moiety of the oven, so that when the one gas main is working, the gas passes through one of these channels into certain of the flues, whilst the waste gases are utilised in heating one of a pair of recuperators, the hot air for the combustion of the gas being supplied by the second regenerator and delivered into the oven through the second channel. When the second gas main is working, the functions of the channels are reversed, and the second recuperator is heated, the hot air being supplied from the first one.—C.S.

Paint or composition; Non-corrosive and antiseptic —— F. E. Dunnet. Fr. Pat. 358,592, Oct. 17, 1905. XIIIA., page 325.

Hydrocarbons; Process of rendering volatile —— *uninflammable such as petroleum spirit (benzine).* A. Boerner and J. Fluss. Fr. Pat. 359,044, Oct. 31, 1905.

To render volatile hydrocarbons uninflammable, and prepare an incombustible solvent for fats, one part of carbon chloride or tetrachloride and two parts of "heavy benzine" are mixed with varying quantities of turpentine spirit, resin, or solutions of resin and heavy hydrocarbons that will dissolve fats. In the product, the "heavy benzine" may be replaced by petroleum, for the purpose of utilising it as an addition to imperfectly refined petroleum, in order to raise the flashing point and specific gravity of the latter according to requirements (see this J., 1905, 962; Eng. Pat. 16, 756).—C. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 261.)

1.4-*Anthraquinone.* H. Dienel. Ber., 1906, **39**, 926—938.

WHEN an alcoholic solution of α-anthrol is boiled in a reflux apparatus for 6—7 hours with sodium nitrite and zinc chloride, in concentrated aqueous solution, two isomeric nitroso compounds, 2.1- and 1.4- nitrosoanthrol, are obtained, which are easily separated by the greater solubility of the zinc salt of the 1.4-derivative. The former crystallises from alcohol in brownish-red or orange needles, decomposing at 200° C., whilst the latter forms glistening, light-brown needles darkening at 205° C., and melting and decomposing at 233° C. On reduction, the corresponding amino compounds are obtained, which, when subjected to oxidation, yield 1.2- and 1.4- anthraquinone. The latter crystallises from alcohol in long yellow needles melting at 206° C. Reduction, acetylation and oxidation led to the formation of quinizarin, which possesses only weak mordant-dyeing properties.—D. B.

ENGLISH PATENTS.

Sulphur colouring matters [Sulphide dyestuffs]; Manufacture of ——. A. Meyenberg, J. T. Alpass and The Clayton Aniline Co., Manchester. Eng. Pat. 11,066, May 26, 1905.

PARA-TOLUYLENEDIAMINE (NH_2:CH_3:NH_2,1:3:4) is heated with twice its weight of sulphur in an oil-bath, to a temperature of 210°—240° C., until the evolution of sulphuretted hydrogen ceases. The melt obtained is insoluble in dilute solutions of sodium sulphide, but if it be heated with caustic alkali or a similar compound to about 140° C., it gives a soluble substance which dyes cotton a yellowish-brown shade from a sodium sulphide bath. By exposure to the air, this is converted into a good olive-green, which is made brighter by treatment with hydrogen peroxide and is darkened by metallic salts.

If the para-toluylenediamine be heated with twice its weight of 40 per cent. formic acid, a compound is obtained which melts at 138°—140° C., and gives a good yellow dyestuff on heating to 240° C. with twice its weight of sulphur. By heating the formic acid derivative with sulphur and sodium sulphide, a brown sulphide dyestuff is formed.—A. B. S.

Lakes [from azo dyestuffs]; Manufacture of new colour ——. C. D. Abel. From Act.-Ges. f. Anilinfabr. Eng. Pat. 15,170, July 24, 1905. XIII*A*., page 325.

UNITED STATES PATENT.

Anthraquinone compound [Anthracene dyestuff] and process of making same. M. H. Isler, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 814,137, March 6, 1906.

Cotton dyed with sulphide blacks; Some remarks concerning Pilling's paper on ——. A. Kertesz. J. Soc. Dyers and Col., 1906, 22, 93—94.

THE author confirms most of Pilling's results (this J., 1906, 216), but, opposed to the latter, states that after-treatment with potassium bichromate and acetic acid, has no perceptible effect in preventing the tendering of cotton dyed with sulphide blacks. He points out that the tendering can always be prevented, as was shown some years ago (see U.S. Pat. 693,653 of 1902; this J., 1902, 471), by arranging that the final treatment of the goods after dyeing is always an alkaline one.—A. S.

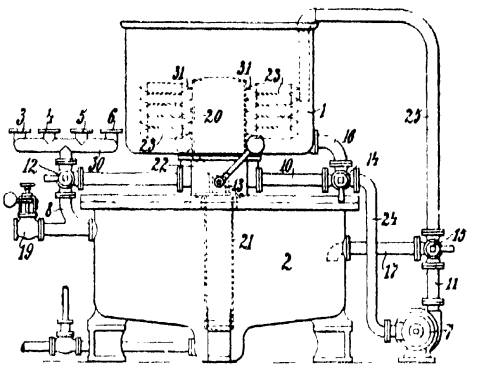
Cotton and linen; Test to differentiate ——. A. Herzog. XXIII., page 338.

ENGLISH PATENTS.

Cellulose [Viscose]; Apparatus for filtering and pumping or regulating the flow of solutions of — —. C. F. Topham. Eng. Pat. 5766, March 18, 1905. XIX., page 333.

Wool lubricant soluble in water. J. W. Riep and G. H. Bauer, Dusseldorf, Germany. Eng. Pat. 7231, April 5, 1905.

100 KILOS. of castor oil are mixed with a solution of 50 kilos. of caustic potash of 50° B. in 50 litres of water, and heated to 99° C. Then 40 litres of water are added slowly so as to prevent the temperature falling appreciably. When the liquid begins to rise in the vessel, another 40 litres of water are added so as to keep the temperature steady (because a rise might cause complete saponification) until the whole mass becomes a thin and clear liquid; this is diluted with water in the proportion of 1 to 5, and is then ready for use.



Only a portion of the oil is saponified, and the remainder is dissolved in the soap formed and the excess of alkali. —A. B. S.

Flax, hemp, jute, tow and similar fibres; Spinning of —— *by the wet process.* P. Heyndrick, A. Delerue, J. Dantzer and E. Mongy, Lille, France. Eng. Pat. 21,922, Oct. 27, 1905.

IN order to soften the gummy matters which are usually present in the "slivers" of the above materials, they are passed through a vessel of water containing zinc chloride, and heated to from 25°—30° C. before going through the process of drawing. The usual amount of zinc chloride employed is 2—3 grms. of the anhydrous salt per litre of water, but the proportion can be varied according to the nature of the textile material.—A. B. S.

Dyeing, mordanting and bleaching of loose materials, spun threads, cops, knitted goods, &c.; Apparatus for ——. O. Venter. Chemnitz, Germany. Eng. Pat. 15,532, July 28, 1905.

THE invention relates to an apparatus in which the dye-liquor, &c., can traverse fabric to be dyed in either direction without reversing the pump, and the apparatus can also be connected with suction or pressure pipes for the purpose of sucking or forcing the liquid through the material to be treated.

The figure shows one form of machine. 1 is the dye-vat proper, which contains the material to be treated (in this case cops) and is open at the top; 2 is the closed dye tank, which is connected with 1 by means of the perforated pipe, 21, the three-way cock, 13, and the vessel, 20, to which are attached the perforated spindles, 23, for holding the cops. 3, 4, 5 and 6 are connections for steam, compressed air, vacuum and water respectively. 12, 14, and 15 are three-way cocks; 7, is a pump, and 19, a reducing value. The other connections are shown in the figure. When the material has been placed in 1, and the dye-liquor in 2, connection can be made between 30 and 8, and between 20 and 21, and by alternately connecting the pipe, 30, to the compressed air or vacuum, the liquid can be forced or sucked through the course, 30, 12, 8, 2, 21, 13, 20, 31, 23, and 1. If it be desired to use the pump the connections are made in the following order:—First 23, 31, 20, 22, 10, 14, 24, 7, 11, 15, 25, 1, whereby the liquor is forced through the material outwards, and then 1, 16, 14, 24, 7, 11, 15, 17, 2, 21, 13, 22, 20, 31, 23; the latter method forces the liquid through the material in the reverse direction to the first and without reversing the pump. By means of 19, a super-pressure of steam or compressed air may be kept up in 2.—A. B. S.

Evaporators for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, waste or spent dyes and the like, and concentrating the solids in the same; the evaporator being also applicable as a smoke washer; Impts. in ——. French Patents.

Woollen tissues ; Machine for washing, scouring, &c., ——. N. Rousselle. Fr. Pat. 358,615, Oct. 18, 1905. Under Int. Conv., April 13, 1905.

Inside the trough, *a* (see Fig.), mounted within the vat, *l*, two tubes, *b* and *h*, are fixed horizontally and parallel to each other. These tubes are closed at one end and connected respectively with the liquor-suction and force pipes of a centrifugal pump, *p*. The tube, *b*, has extending along it a V-shaped slit, *c*, wider in the middle and narrower towards the ends. The other tube, *h*, has in it a narrow, longitudinal slit, *m*, and is provided internally with a removable filter for the interception of matters in suspension in the water and in the solutions employed in the washing and scouring operations. The woollen tissues to be scoured are sewn together end to end and are drawn through the trough at full width and in a continuous manner by means of squeezing rollers, passing successively, in contact with the two tubes, immediately in front of the slits. As the liquors are thus forced through the tissues, more thorough scouring than has hitherto been effected, is produced, whilst certain classes of tissues, *e.g.*, flannels, which are subsequently to have their surface "raised," are left in a condition very suitable for that process.—E. B.

Yarns in the form of bobbins; Apparatus for dyeing cross-wound ——. A. Sedeyn. Fr. Pat. 358,670, Oct. 19, 1905. Under Int. Conv., Sept. 25, 1905.

THE usual, intermediate, perforated tube upon which yarns

Fig. 1.

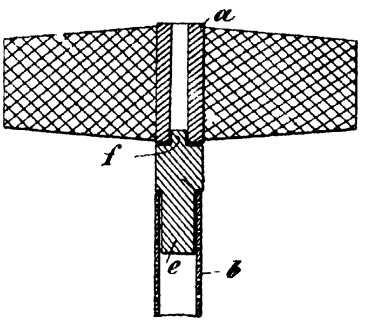

Fig. 2.

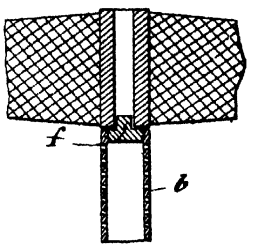

Fig. 3.

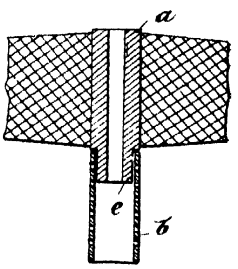

Fig. 6.

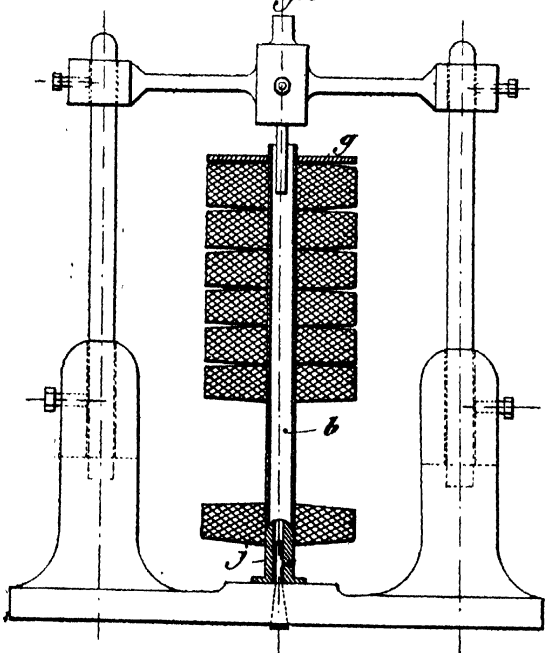

Fig. 5.

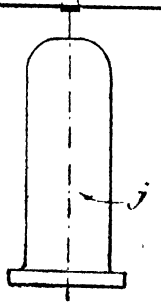

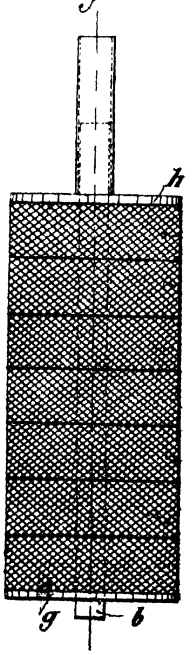

Fig. 4.

are wound in the form of "cheeses" or bobbins, before being placed upon the inner, perforated tube on which they are dyed, is dispensed with, the yarns being wound upon a tube, *a* (see figures), and forced from this, either directly (one end, *e*, of the tube being in this case made to fit into the dye-tube), or, indirectly (over a solid end-piece, *f*), on to the perforated pipe, *b*, of the dyeing apparatus. To the bottom of the latter pipe a plate, *g*, is attached (Fig. 4), above which the bobbins are placed successively in position. When almost the whole length of the pipe has been covered by the bobbins, a second plate, *h*, to which a sleeve-pipe is affixed, is fitted to the top. Pressure is applied to the upper plate to bring the two plates nearer together and so to compress the bobbins and cause them to form a compact mass around the central pipe. The dyeing is then performed in the usual manner by drawing or forcing dye-liquors alternately in opposite directions through the yarns. Afterwards the pipe with the yarns upon it is withdrawn from the dyeing apparatus, and, the cover plate being removed, is placed in an inverted position above a portable unwinding tube, *j*, upon which each bobbin is in turn received and from which the yarn composing it is unwound.—E. B.

Paintings; Producing —— fast to washing, on textile tissues, &c. E. Hottenroth, *née* Cloété-Brown. Fr. Pat. 358,554, Oct. 16, 1905.

PAINTINGS, fast to washing with water and to soaping, are produced upon tissues, &c., by means of mixtures containing, in addition to a pigment, an agglutinant, such as gum arabic, and a bichromate, *e.g.*, potassium bichromate. Each tint or layer of colour is separately applied, in dull daylight or non-actinic light, then exposed to light and the tissue, &c., washed and dried.—E. B.

Waterproof tissues and a process of manufacturing the same. L. A. Bond. Fr. Pat. 358,619, Oct. 18, 1905.

TISSUES, cordage, &c., are rendered impermeable to water by a passage, at a temperature of about 200° C., through melted bitumen (bitumen melting at about 175° C. is suitable), the excess of the latter being removed by means of squeezing rollers, followed by passages first through the air to cool and partially set the bitumen and then through a box containing a suitable "siccative," *e.g.*, steatite. The goods may, if desired, be afterwards passed between polishing rollers to render their surfaces smooth. The materials thus treated, it is stated, may be employed with advantage in place of materials made waterproof by means of indiarubber or tar.—E. B.

Alkali chromates. F. A. H. Schreinemakers. Z. physik. Chem., 1906, **55**, 71—98.

THE results of further work on the alkali chromates are given (see this J., 1905, 1170, 1171). The tri- and tetra-chromates of sodium are soluble in water without decomposition. The solubility of the alkali mono- and bichromates in water is shown in the following table:—

100 *grms. of water at* 30° C. *will dissolve:*	
Ammonium chromate	40.46 grms.
Potassium chromate	64.91 ,,
Sodium chromate	87.36 ,,
Lithium chromate	99.94 ,,
Ammonium bichromate.....	47.17 ,,
Potassium bichromate	18.12 ,,
Sodium bichromate	197.6 ,,
Lithium bichromate	130.4 ,,

—A. S.

Borates of the alkali metals and of ammonia [and barium]. A. Atterberg. Z. anorg. Chem., 1906, **48**, 367—373.

FIVE different potassium borates are obtainable, *viz.*, a monoborate, $K_2O,B_2O_3,3H_2O$, which crystallises only from alkaline solutions: its aqueous solutions dissociate, a diborate being obtained, *viz.*, $K_2O,2B_2O_3,4H_2O$. Two other diborates, crystallising with $5\frac{1}{2}$ and 6 mols. of water respectively, are obtained from aqueous solutions containing 1 mol. of potassium hydroxide to 2 of boric anhydride. A potassium pentaborate, $K_2O,5B_2O_3,8H_2O$, has been prepared by Laurent. Sodium monoborates containing $4\frac{1}{2}$, $5\frac{1}{2}$ and 8 mols. of water of crystallisation, were all obtained from solutions containing equal molecules of sodium hydroxide and boric anhydride. Sodium diborate crystallises with 5 and with 10 mols. of water; a sodium pentaborate, $Na_2O,5B_2O_3,10H_2O$, was also obtained the aqueous solutions of which partially dissociate. An ammonium diborate, $(NH_4)_2O,2B_2O_3,5H_2O$, and a pentaborate, $(NH_4)_2O,5B_2O_3,8H_2O$, are obtainable: the latter was prepared by adding ammonia to hot boric acid solution in the proportion of 1 mol. of ammonia to $3\frac{1}{2}$ of boric acid. In no case could triborates or tetraborates of the alkali metals or of ammonia be prepared. Barium forms two monoborates, crystallising with 2 and 4 mols. of water respectively, and a sesquiborate, $2BaO,3B_2O_3,7H_2O$; this last was obtained by adding boric acid solution to excess of baryta water; when heated with baryta water, this sesquiborate is converted into the monoborate crystallising with 2 mols. of water; that with 4 mols. of water is produced by heating boric acid for a long time with excess of baryta water.—T. F. B.

Magnesium permanganate as an oxidising agent. A. Michael and W. W. Garner. Amer. Chem. J., 1906, **35**, 267—271.

ANHYDROUS magnesium permanganate is a much more powerful oxidising agent than the potassium salt. It is best prepared by Mitscherlich's method: by the interaction of barium permanganate and magnesium sulphate. It was found to be insoluble in many organic solvents, forming stable solutions only in glacial acetic acid and in pyridine. It dissolves in methyl alcohol which is slowly oxidised, but ethyl and propyl alcohols are attacked at once. Methyl and ethyl acetates also dissolve it slightly, the solutions being tolerably stable. It is best used in glacial acetic acid, since pyridine has a remarkable inhibiting effect on its action. Propionic acid and its higher homologues and the hydroxy- and keto-acids are immediately destroyed by it. Aliphatic ketones are at once attacked, though potassium permanganate decomposes them with difficulty. Thus, a solution of potassium permanganate in acetone may be boiled without decomposition, but this solvent is at once oxidised by the magnesium salt. Even benzene, as well as its derivatives, may be oxidised completely to carbon dioxide and water, and the aliphatic hydrocarbons, from hexane upwards, give the same products.—F. SODN.

Lead chloride and lead acetate; Reactions between ——. J. White. Amer. Chem. J., 1906, **35**, 217—227.

THE author has studied the reactions determining the solubility of lead chloride in lead acetate solution, and

has succeeded in isolating two new crystalline salts, mixed chloro-acetates of lead, to one of which he assigns the formula $PbCl.C_2H_3O_2,C_2H_4O_2$, the other possibly containing the complex $PbCl.C_2H_3O_2,Pb(C_2H_3O_2)_2$. The former of these is produced when lead chloride is dissolved in a hot glacial acetic acid solution of lead acetate, and is decomposed by water. The latter crystallises from a solution of lead chloride in aqueous lead acetate. It is soluble in water, but decomposed by acetic acid. These compounds are analogous to those previously described with lead iodide (Amer. Chem. J., 1904, **31**, 1). But whereas lead chloride and alkali acetates undergo double decomposition, lead iodide forms compounds with these salts.—F. SODN.

Lead; Reactions during the formation of certain complex salts of ——. [*New iodoacetate of lead.*] J. White and J. M. Nelson. Amer. Chem. J., 1906, **35**, 227—235. (Compare previous abstract.)

A NEW iodoacetate of lead has been obtained $(PbI.C_2H_3O_2)_5\ Pb(C_2H_3O_2)_2$, by the interaction of methyl iodide and lead acetate in glacial acetic acid, a slight modification of Carius's method being adopted. A good result was obtained by heating a mixture of 6 grms. of methyl iodide, 10 grms. of lead acetate, 6 c.c. of acetic acid, and 2 c.c. of acetic anhydride, at 60°—70° C. for about 6 hours. The crystals resulting were washed with alcohol. The influence of temperature and of relative mass have been worked out, and the possible mechanism of the reaction is discussed in the paper.—F. SODN.

Platinum and iridium salts; Action of sulphuric acid on ——, *in presence of ammonium sulphate.* [*Detection of iridium in commercial platinum.*] M. Delépine. Comptes rend., 1906, **142**, 631—633.

As much as 2 grms. of platinum can be dissolved in 100 c.c. of concentrated sulphuric acid by prolonged boiling (40—50 hours). These solutions probably contain a platinosulphuric acid, much less easily reducible than chloroplatinic acid; for they deposit their platinum much less readily when heated with ammonium sulphate than with ammonium chloride.

Iridioplatinum containing 10 per cent. of iridium is attacked by sulphuric acid much less readily than platinum; but it dissolves as a whole, the undissolved portion still containing 10 per cent. of iridium. On heating with ammonium salts, the iridium remains dissolved, forming a green solution, which turns deep violet when boiled with a little nitric acid. This violet colour is so intense that it is possible by its means to detect iridium in many samples of commercial "pure platinum." The green solution contains the ammonium salt of iridiosulphuric acid. The author has distinguished three varieties of these iridiosulphates—(1) green, yielding a blue precipitate with barium or strontium salts, slowly decomposed by ammonia in the cold (described by Lecoq de Boisbaudran); (2) green, precipitated by barium salts from alkaline solutions only, as greenish-brown compound, and giving with ammonia an olive-brown solution; (3) olive-brown, not precipitated by barium salts unless ammonia is present.—J. T. D.

Metal-ammoniums; Nature of ——. O. Ruff and E. Geisel. Ber., 1906, **39**, 828—843.

THE authors find that the so-called alkali-metal-ammoniums are not compounds at all, but consist of a mixture of the metal with adhering saturated liquid solution of metal in liquid ammonia. They have determined the solubility at various temperatures of the alkali-metals in liquid ammonia, and find no other phase, either solid or liquid, than metal and saturated solution. The small amounts of heat which Joannis has found to be evolved during the solution of sodium or potassium in liquid ammonia, are probably attributable to the fact that the metals exist in solution not in the monatomic condition, but as Na_2 and K_2. Whether the alkaline-earth metal-ammoniums are of a similar nature is not yet established.—J. T. D.

Selenium dioxide. O. de Coninck. Comptes rend., 1906, **142**, 571—573.

THE paper contains determinations of the solubility of selenium dioxide in water, ethyl and methyl alcohols, acetone, and acetic acid, and also of the density of aqueous solutions, in addition to notes as to the reactions of selenium dioxide with acids, chlorides of phosphorus and hydrazine.—E. F. A.

Nitrogen peroxide; Reaction of ——, *on ammonia and ammonium salts.* Besson and Rossett. Comptes rend., 1906, **142**, 633—634.

LIQUID ammonia reacts violently on solid nitrogen peroxide; if ammonia gas be slowly brought into contact with the peroxide, the reaction proceeds more smoothly. Nitrogen peroxide also acts on ammonium salts, though heating to 100° C. in sealed tubes is then necessary to complete the reaction.—J. T. D.

Carbon dioxide; Liquefied —— *as a solvent.* E. H. Büchner Z. physik. Chem., 1906, **54**, 665—688.

A NUMBER of different inorganic and organic substances were examined as to their solubility in liquid carbon dioxide. *p*-Dichlorobenzene, acetic acid (?), camphor, ethyl alcohol (?), carbon bisulphide, ether, pentane, amylene, acetylene, benzene, and *p*-xylene are completely miscible, in the liquid condition, with liquid carbon dioxide, the solubility curve being throughout below the curve representing the critical temperature of solution. In other cases, the solubility curve cuts the critical temperature curve, *e.g.*, with naphthalene, phenanthrene, iodoform, *p*-dibromobenzene, borneol, substituted phenols (except nitrophenol), *p*-chloro-(or bromo-) nitrobenzene, 1.2.3- and 1.3.2- dichloronitrobenzene, phthalic anhydride, succinic anhydride, *a*-naphthylamine, urea, benzamide, and nearly all inorganic substances with the exception of gases. In still other instances, the substances in the liquid condition are partially soluble in liquid carbon dioxide, the solubility being increased on heating, in the case of bromoform and propyl, butyl and isobutyl alcohols; and diminished in the case of urethane, thymol, *o*-nitrophenol, nitrobenzene, the mono- and dichloro-nitrobenzenes not previously mentioned, and *o*-bromonitrobenzene.

Liquid carbon dioxide resembles liquid cyanogen in possessing only a small solvent power, and in this respect, differs sharply from liquefied sulphur dioxide and ammonia, which are good solvents for inorganic salts, and from liquefied hydrochloric, hydrobromic and hydriodic acids, and hydrogen sulphide, in which many organic substances are easily soluble.—A. S.

Chlorine gas; Use of —— *under moderate pressures in the chemical arts.* E. A. Ashcroft. Electrochem. and Met. Ind., 1906, **4**, 91—94.

THE use of chlorine under moderate pressures is possible only if the gas be perfectly dry, in which condition it does not attack any of the ordinary metals. For compressing the gas, the author obtained satisfactory results only by the use of ordinary metal reciprocating pumps with displacement plungers and oil-seals. The chlorine was dried by means of zinc chloride. For lubricating purposes and for the oil-seals, chlorine-proof whale oil was used, which was prepared in the following manner:—Good sperm whale oil was treated with chlorine until chemical action (indicated by rise of temperature) ceased, and was then treated with zinc oxide to neutralise acidity.

The author states that of many oils tried, the treated whale-oil was the only one to prove quite satisfactory.
—A. S.

Ozone; Conversion of oxygen into —— *at high temperatures; and oxidation of nitrogen.* F. Fischer and F. Braehmer. Ber., 1906, **39**, 940—968.

OZONE may be formed from oxygen at high temperatures. It has often been suspected, but never satisfactorily proved. Ozone being endothermic, should be more stable at high temperatures, and the great rapidity of its decomposition as the temperature falls, no doubt accounts for the fact of its formation never having been demonstrated. The authors have exposed oxygen and air to high temperatures, produced both by chemical and by electrical means, in the immediate presence of liquid air or oxygen, so as to

are wound in the form of "cheeses" or bobbins, before being placed upon the inner, perforated tube on which they are dyed, is dispensed with, the yarns being wound upon a tube, *a* (see figures), and forced from this, either directly (one end, *e*, of the tube being in this case made to fit into the dye-tube), or, indirectly (over a solid end-piece, *f*), on to the perforated pipe, *b*, of the dyeing apparatus. To the bottom of the latter pipe a plate, *g*, is attached (Fig. 4), above which the bobbins are placed successively in position. When almost the whole length of the pipe has been covered by the bobbins, a second plate, *h*, to which a sleeve-pipe is affixed, is fitted to the top. Pressure is applied to the upper plate to bring the two plates nearer together and so to compress the bobbins and cause them to form a compact mass around the central pipe. The dyeing is then performed in the usual manner by drawing or forcing dye-liquors alternately in opposite directions through the yarns. Afterwards the pipe with the yarns upon it is withdrawn from the dyeing apparatus, and, the cover plate being removed, is placed in an inverted position above a portable unwinding tube, *j*, upon which each bobbin is in turn received and from which the yarn composing it is unwound.—E. B.

Paintings; Producing —— fast to washing, on textile tissues, &c. E. Hottenroth, *née* Cloété-Brown. Fr. Pat. 358,554, Oct. 16, 1905.

PAINTINGS, fast to washing with water and to soaping, are produced upon tissues, &c., by means of mixtures containing, in addition to a pigment, an agglutinant, such as gum arabic, and a bichromate, *e.g.*, potassium bichromate. Each tint or layer of colour is separately applied, in dull daylight or non-actinic light, then exposed to light and the tissue, &c., washed and dried.—E. B.

—A. S.

Borates of the alkali metals and of ammonia [and barium]. A. Atterberg. Z. anorg. Chem., 1906, **48**, 367—373.

FIVE different potassium borates are obtainable, *viz.*, a monoborate, $K_2O,B_2O_3,3H_2O$, which crystallises only from alkaline solutions: its aqueous solutions dissociate, a diborate being obtained, *viz.*, $K_2O,2B_2O_3,4H_2O$. Two other diborates, crystallising with $5\frac{1}{2}$ and 6 mols. of water respectively, are obtained from aqueous solutions containing 1 mol. of potassium hydroxide to 2 of boric anhydride. A potassium pentaborate, $K_2O,5B_2O_3,8H_2O$, has been prepared by Laurent. Sodium monoborates containing $4\frac{1}{2}$, $5\frac{1}{2}$ and 8 mols. of water of crystallisation, were all obtained from solutions containing equal molecules of sodium hydroxide and boric anhydride. Sodium diborate crystallises with 5 and with 10 mols. of water; a sodium pentaborate, $Na_2O,5B_2O_3,10H_2O$, was also obtained the aqueous solutions of which partially dissociate. An ammonium diborate, $(NH_4)_2O,2B_2O_3,5H_2O$, and a pentaborate, $(NH_4)_2O,5B_2O_3,8H_2O$, are obtainable: the latter was prepared by adding ammonia to hot boric acid solution in the proportion of 1 mol. of ammonia to $3\frac{1}{2}$ of boric acid. In no case could triborates or tetraborates of the alkali metals or of ammonia be prepared. Barium forms two monoborates, crystallising with 2 and 4 mols. of water respectively, and a sesquiborate, $2BaO,3B_2O_3,7H_2O$; this last was obtained by adding boric acid solution to excess of baryta water; when heated with baryta water, this sesquiborate is converted into the monoborate crystallising with 2 mols. of water; that with 4 mols. of water is produced by heating boric acid for a long time with excess of baryta water.—T. F. B.

Magnesium permanganate as an oxidising agent. A. Michael and W. W. Garner. Amer. Chem. J., 1906, **35**, 267—271.

ANHYDROUS magnesium permanganate is a much more powerful oxidising agent than the potassium salt. It is best prepared by Mitscherlich's method: by the interaction of barium permanganate and magnesium sulphate. It was found to be insoluble in many organic solvents, forming stable solutions only in glacial acetic acid and in pyridine. It dissolves in methyl alcohol which is slowly oxidised, but ethyl and propyl alcohols are attacked at once. Methyl and ethyl acetates also dissolve it slightly, the solutions being tolerably stable. It is best used in glacial acetic acid, since pyridine has a remarkable inhibiting effect on its action. Propionic acid and its higher homologues and the hydroxy- and keto-acids are immediately destroyed by it. Aliphatic ketones are at once attacked, though potassium permanganate decomposes them with difficulty. Thus, a solution of potassium permanganate in acetone may be boiled without decomposition, but this solvent is at once oxidised by the magnesium salt. Even benzene, as well as its derivatives, may be oxidised completely to carbon dioxide and water, and the aliphatic hydrocarbons, from hexane upwards, give the same products.—F. SODN.

Lead chloride and lead acetate; Reactions between ——. J. White. Amer. Chem. J., 1906, **35**, 217—227.

THE author has studied the reactions determining the solubility of lead chloride in lead acetate solution, and

and dried, may be used in producing antimonial colours or may be reduced to metal. To separate arsenic from an antimonial solution containing it, freshly precipitated antimony sulphide is introduced into the solution, which is boiled, when the arsenic is precipitated as sulphide. —E. S.

Antimony oxides and other metallic oxides; Manufacture of ——. G. C. Genton. Fr. Pat. 359,075, Nov. 2, 1905.

The vapours and fumes from the roasting kiln are drawn through a series of vertical connected rectangular channels contained within a rectangular sheet iron vessel through which cold water continually flows. The channels communicate by arched continuations above, and open through the bottom of the vessel into a vacant closed compartment for each pair of the channels, so that the vapours are led successively down and up through the cooled channels, and at the end of the series of such channels into a condensing chamber, in which, it is stated, pure antimony trioxide, free from the insoluble oxide, collects.—E. S.

Arsenic sulphide; Method of utilising crude ——. F. Howles. Fr. Pat. 359,028, Oct. 31, 1905. Under Int. Conv., Nov. 8, 1904.

See Eng. Pat. 24,198 of 1904; this J., 1905, 1230.—T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 267.)

English Patent.

Pigments from glass; Manufacture of permanent ——. J. B. Bennett and J. Mastin. Eng. Pat. 15,398A, July 27, 1905. XIIIA., page 325.

United States Patent.

Glass; Manufacture of ——. F. L. O. Wadsworth, Morgantown, W. Va. U.S. Pat. 814,631, March 6, 1906.

The process described of forming glass sheets consists in rolling a mass of glass into sheets between non-absorbent surfaces, and interposing a gaseous fluid film, *e.g.*, of steam, between the glass and the forming surface, at the point of application of pressure, and discharging the gaseous fluid, as the sheet is formed. In the case of glass with a pattern-surface, the glass is spread over a pattern-forming surface, and comes into direct contact with it, only after the gaseous fluid has been discharged. The table on which the glass is spread, is provided with a channel in which a piston works, and as this moves along, it forces steam through openings in the forming surface, and the rear part of the piston draws off the fluid from the openings it has passed.—W. C. H.

French Patent.

Ceramic colours and fluxes; Preparation of —— by precipitation. H. Renoul. Fr. Pat. 358,988, Jan. 7, 1905.

The ceramic colours and fluxes are obtained in impalpable powders, by precipitating in aqueous solutions, silicates and borates of alkali, alkaline-earth or heavy metals. The claims also include the articles thus obtained, and their application in ceramic industries.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 267.)

Sand-lime brick. E. W. Lazell. Engineers' Club of Philadelphia, Nov. 4, 1905. Eng. and Mining J., 1906, 81, 374–376.

The author describes the manufacture, properties, uses and advantages of sand-lime bricks. A comparison of sand-lime brick with ordinary clay-brick and sandstone is given in the following table:—

Material.		Crushing strength, lb. per sq. in.	Absorption, per cent.	Crushing wet, after absorption, lb. per sq. in.	Freezing, percentage loss in weight.	Crushing after freezing, lb. per sq. in.
Sand-lime brick, common	Aver.	2718	15·07	1899	0·41	3023

Cement testing. O. H. Klein and S. F. Peckham. Report on Portland cements. J. C. Hertle and W. H. Black, July 27, 1905. XXIII., page 338.

English Patents.

Wood: Composition of matter for impregnating ——. K. H. Wolman, Idaweiche, Germany. Eng. Pat. 7043, April 3, 1905.

See Fr. Pat. 353,181 of 1905; this J., 1905, 971.—T.F.B.

Cement from furnace slag; Manufacture of ——. H. Colloseus, Berlin. Eng. Pat. 3619, Feb. 21, 1905. Under Int. Conv., Nov. 3, 1904.

See Fr. Pat. 356,276 of 1905; this J., 1905, 1307.—T.F.B.

Cements; Process for manufacturing hydraulic binding substances or ——. A. J. Boult, London. From M. Reiche, Paris. Eng. Pat. 4194, Feb. 28, 1905.

Calcium hydroxide is mixed with cement-forming oxides or hydroxides in the proportion of not more than 2 mols. to 1 mol. of silica, alumina or ferric oxide, and the mixture is heated with water under pressure or exposed to the action of superheated steam. The acid material must be very finely ground, leaving not more than 20 to 30 per cent. residue on a 4400-mesh sieve. Other oxides, *e.g.*, of chromium, manganese, zinc, copper, tin, antimony, may be used as the acid material if coloured cements are desired. Portland cement may be made by calcining a mixture of the proper ingredients after treating, as above, the whole or a part of the mixture. Artificial stone may be obtained by adding silicious sand to a mixture treated as above and again steaming.—A. G. L.

Cement; Manufacture of Portland ——. The Associated Portland Cement Manufacturers (1900), Ltd., H. K. G. Bamber and G. R. M. Layton, all of London. Eng. Pat. 5765, March 18, 1905.

The rotary cement kiln is made in two parts, which may

be revolved at different speeds if necessary. The raw materials are dried in the upper part and are prevented from falling directly into the lower part of the kiln by an annular diaphragm which, however, allows the passage of hot gases upwards. Instead, the dried raw materials fall through a series of apertures into a shoot leading to a grinding machine, being made to pass through a trap on their way in order to prevent hot gases from reaching the grinding machine, and are then raised and again introduced into the lower part of the kiln through a second series of apertures, the whole being done without sensible loss of heat.—A. G. L.

Clinker from refuse destructor furnaces; Treatment of ——. J. A. Brodie. Eng. Pat. 7521, April 10, 1905. XVIII*B.*, page 332.

Salt pans; Treatment of pan scale of ——, *and of its products and apparatus used.* F. Bale. Eng. Pat. 10,722, May 23, 1905. VII., page 315.

[*Cement*] *kilns; Rotary* ——. W. R. Warren, New York. Eng. Pat. 17,457, Aug. 29, 1905.

SEE Fr. Pat. 358,227 of 1905; this J., 1906, 182.—T.F.B.

UNITED STATES PATENTS.

Cement-kiln. T. A. Edison, Llewellyn Park, N.J. U.S. Pat. 813,490, Feb. 27, 1906.

THIS invention relates to kilns of the rotary type, and comprises a pair of cylindrical sections with abutting flanges, and a shoe to cover the flanges; the shoe consists of two sets of L-shaped sections, placed opposite to each other, and secured to the flanges by securing-flanges, and having bearing surfaces, the sections of one set being placed so as to "break joints" with the other set.—W. C. H.

Cement-burning process, and apparatus therefor. B. E. Eldred, Brookline, Mass., Assignor to Combustion Utilities Co., New York. U.S. Pat. 813,627, Feb. 27, 1906.

ACCORDING to this invention cement-forming material is fed into the upper end of a reverberative chamber, or rotary kiln. Adjacent to the lower end of the chamber is an external fuel bed, from which a calcining flame of low temperature is supplied. This flame is regulated by means of a gaseous diluent passed through the fuel from below upwards; the diluent suggested is a portion of the stack gases, which are drawn through a pipe from the stack, and introduced below the grate by means of a fan. To produce a local intensification of this flame to raise it to a clinkering temperature, a jet of air is introduced into the chamber, to intercept the flame or gas current, and is directed on to the material on the floor of the chamber; this jet commands the outlet end of the chamber. The external fire-box is separated from the burning chamber by a partition, arranged to form a number of openings in the chamber, one of which is commanded by the jet-nozzle, mounted on the partition.—W. C. H.

Cement-kilns; Heat-regulator for ——. C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 813,630, Feb. 27, 1906.

THE apparatus described comprises a kiln, of the rotary type, and a regenerative chamber, for abstracting heat from the waste gases. The regenerator consists of a number of chambers lined with refractory materials, and between these chambers, others, provided with baffle-plates, for collecting dust. Means are provided for withdrawing a portion of the waste gases, after passing through the heater, and adding it to the heated air. The gas-exit end of the kiln is provided with a "housing" to which the chimney stack is also connected. Immediately below the chimney, and connected with the "housing," is a chamber of the regenerative air-heater, for abstracting a portion of the waste-gases from the "housing."—W. C. H.

Cement and cement construction; Method of treating ——. M. Toch, Assignor to H. M. Toch, New York. U.S. Pat. 813,841, Feb. 27, 1906.

THE method of treating Portland cement construction, to render it oil- and water-proof, consists in applying to the surface a suitable organic acid, such as an acid resin, or a compound such as calcium resinate; the solution may also contain a vegetable drying oil and a diluent. A mixture containing a dissolved resin and a pigment may be applied to the former layer.—W. C. H.

Binding agent and process of making same. L. Weiss, Budapest, Austria-Hungary. U.S. Pat. 814,490, March 6, 1906.

SEE Eng. Pat. 4939 of 1904; this J., 1904, 607.—T. F. B.

X.—METALLURGY.

(*Continued from page* 270.)

Cupriferous tailings; Cyanide treatment of —— *by the sulphuric acid process.* W. S. Brown. Inst. of Min. and Met., March 15, 1906. [Advance proof].

THE tailings were produced many years since at the Cobar-Chesney Mine, Cobar, N.S.W. Shallow rectangular wooden vats, each holding about 25 tons, were provided for the preliminary acid treatment. When loaded with ore, from 10 to 12 tons of dilute sulphuric acid were pumped on and then drained off slowly and intermittently through a launder. The first portion of this acid wash never showed any free acid, later portions were either made up with sulphuric acid for use with another charge or run to waste. Twenty-five tons of water were then run through as a wash, followed by a second wash of about half that quantity, the total treatment occupying 48 hours. All the solutions were passed through the precipitating boxes, which were loaded with scrap sheet iron. The washed ore from three acid vats, after being covered with 0·5—0·8 per cent. of lime, was run out and trucked to cyanide vats, each holding 75 tons of tailings. Fifteen tons of weak cyanide solution were first applied to displace the weak acid present. This was run to a special sump and subsequently used as a final wash. After draining off this weak solution, from 50 to 60 tons of 0·3 per cent. cyanide solution were pumped on and drained off in several separate portions; this was followed by 20 to 30 tons of weak solution, and finally by 15 tons of wash. Zinc-box precipitation was employed for the golds From the 1st to the 11th of October, 450 tons of tailing. were treated which yielded 167·7 oz. of gold. The average value of the tailings was 9 dwt. 4 grs., of which 81·1 per cent. was recovered. 20·1 lb. of 92 per cent. sulphuric acid were used per ton of tailings or 5·5 lb. in excess of the theoretical requirement; 7·1 lb. copper per ton were recovered. The cyanide consumption was 1·6 lb., the scrap iron used cost 1.5d., the lime cost 3s. 6d., and the zinc 2s. 0d. per ton of tailings. The working solutions seldom showed over 0·3 per cent. of copper, the shipments of precipitate averaged about 60 per cent of copper, the remainder consisting of iron and silica. The produce of the zinc boxes was extremely base, both copper and lead being present in notable proportions. After treatment with sulphuric acid, bullion 900 fine was produced.—J. H. C.

Alloy. U.S. Customs Decision, Jan. 16, 1906.

THE United States Circuit Court of Appeals held that an alloy composed of iron 62 per cent., manganese 6 per cent., and tin 32 per cent., and used in hardening bronze, is dutiable at 20 per cent. *ad valorem*, under paragraph 183 of the tariff, as a "metal unwrought." The claim of the importers that it was dutiable by similitude to ferro-manganese at 4 dols. per ton, under paragraph 122, was overruled. [T.R.] R. W. M.

Gold-zinc and gold-cadmium alloys. R. Vogel. Z. anorg. Chem., 1906, **48**, 319—346.

GOLD forms three chemical compounds with zinc, corresponding to the formulæ $AuZn$, Au_3Zn_8 and $AuZn_8$, and two with cadmium, represented by Au_4Cd_5 and $AuCd_3$.

Microphotographs are given showing the structure of certain metallic mixtures, and also the cooling curves of the gold-zinc and gold-cadmium mixtures.—T. F. B.

Silver-zinc alloys. G. I. Petrenko. Z. anorg. Chem., 1906, **48**, 347—363.

Conclusive evidence was obtained of the existence of four alloys of silver and zinc: these correspond to the formulæ Ag_3Zn_2, $AgZn$, Ag_2Zn_3, Ag_2Zn_5.—T. F. B.

Ferromagnetic alloys of non-magnetic metals; Heusler's ——. E. Haupt. Naturw. Rundsch., 1906, **21**, 69—71. Chem. Centr., 1906, **1**, 906. (See this J., 1904, 985; 1905, 850, 1237.)

At high temperatures all metals lose their magnetisability. For iron the transformation point is at about 800° C., and for nickel at about 400° C. In the case of manganese-aluminium bronzes, the transformation temperature rises as the proportion of manganese is increased, and also, if the percentage of manganese is kept constant, as the proportion of aluminium is increased. An alloy containing 61 per cent. of copper, 27 per cent. of manganese and 12 per cent. of aluminium, is still magnetisable at 310° C., but an alloy of 76 per cent. of copper, 16 per cent. of manganese and 8 per cent. of aluminium becomes non-magnetic at 160° C., and if contaminated with lead, at 60°—70° C. Stronger heating diminishes the magnetisability permanently. The maximum magnetisability is attained in the case of alloys containing manganese and aluminium in the proportions of their atomic weights. The analogy between the behaviour of the manganese-aluminium bronzes and the magnetisable manganese salts and their solutions is favourable to the assumption that these bronzes are solutions of manganese-aluminium compounds in copper. Manganese-aluminium bronzes remain ferromagnetic even on addition of other non-magnetic metals; lead, for example, increases the magnetisability appreciably.—A. S.

Bronzes; Malleable magnetic ——. F. Heusler. Sitzungsber. Ges. Beförd. ges. Naturwissenschaften zu Marburg, Nov., 1905, 98—99. Chem. Centr., 1906, **1**, 817.

After referring to previous work on the magnetic alloys free from iron, discovered by the author (see this J., 1904, 985; 1905, 850, 1237), attention is drawn to the important fact that certain manganese-aluminium bronzes rich in copper, which can be strongly magnetised, are capable of being forged. The forged alloys lose their magnetic properties when quenched in water, but become magnetisable again on keeping. (See preceding abstract.)—A. S.

Aluminium, copper and aluminium-bronze; Tensile overstrain and recovery of ——. A. Morley and G. A. Tomlinson. Phil. Mag., 1906, **11**, 380—392.

Ewing (Roy. Soc. Proc., 1895, **58**) has shown that the overstrained state, in the case of iron and steel, gradually disappears, and that the material approaches its original condition after a sufficient interval of time. Muir (Phil. Trans. Roy. Soc., 1899, **193**; this J., 1901, 254) found that this recovery is greatly accelerated by heating the metal to such moderate temperatures as 100° C. The authors have investigated the cases of overstrained aluminium, copper and an aluminium-bronze composed of aluminium, 10, and copper, 90 per cent. As with iron and steel, overstrained aluminium recovers its properties with rest, and more quickly by the application of heat. The recovery is nearly complete after 14 days, whilst Muir found that steel shows recovery to greater hardness than the original in 17 days. Copper is either not altered by overstrain, or if altered, it recovers its properties very rapidly. With overstrained aluminium-bronze the recovery with lapse of time is slow, but is very rapid under the influence of a moderate degree of heat. Mechanical vibration increases the injurious effects of overstraining and retards the recovery in the case of aluminium bronze, but has no appreciable influence on overstrained aluminium.—A. S.

Copper; Action of sulphuric acid on ——. C. H. Sluiter. Chem. Weekblad, 1906, **3**, 63—66. Chem. Centr., 1906, **1**, 903—904.

The author upholds the "reduction theory" of the action of sulphuric acid on copper and gives the following equations as representing the reactions:—

$Cu + H_2SO_4 = CuSO_4 + 2H$; $2H + H_2SO_4 = SO_2 + 2H_2O$.

It is stated that the only plausible explanation of the formation of copper sulphide is that the sulphur dioxide produced first, is further reduced to hydrogen sulphide by hydrogen. That hydrogen is present among the reaction products was proved by an experiment in which a nitrobenzene solution of sulphuric acid was heated with copper to 130° C., when it was found that aniline was formed. Nitrobenzene is not affected by heating with 96 per cent. sulphuric acid to 200° C., or by heating with water and copper to 100° C., and is not reduced by sulphur dioxide.—A. S.

Copper sulphate; Decomposition of the aqueous solution of —— *by aluminium alloys.* H. Pécheux. Comptes rend. 1906, **142**, 575—577.

The author's experiments show that magnesium-aluminium alloys acting on aqueous copper sulphate solution bring about a reduction of the water and evolution of hydrogen, solely due to the action of the magnesium; and a reduction of the copper sulphate with a deposition of red copper entirely due to the aluminium.

Tin-aluminium alloys cause a similar decomposition which, however, stops very soon, the alloy becoming coated with an insoluble surface film of alumina.—E. F. A.

Silicon chloride; Action of ——, *on cobalt.* E. Vigouroux. Comptes rend. 1906, **142**, 635—637.

At a high temperature, cobalt reacts on silicon chloride to form cobalt chloride and silicide; the action ceases when the silicon content of the residue (from which the cobalt chloride is separated by volatilisation) is 19—20 per cent., corresponding to the formula Co_2Si.—J. T. D.

Platinum and iridium salts; Action of sulphuric acid on —— *in presence of ammonium sulphate.* [*Detection of iridium in commercial platinum.*] M. Delépine. VII., page 314.

Mercury ores; Assay of —— . G. T. Holloway. XXIII., page 338.

Mineral production of Canada. Eng. and Mining J., March 17, 1906.

A preliminary report, issued by the Geological Survey of Canada, shows that the mineral production of the Dominion during the year 1905 was valued at 63,574,707 dols., as compared with 60,073,987 dols. in 1904. As an indication of the enormous increase in the mineral industry of Canada, it may be stated that the production in 1896 was 22,584,513 dols., and in 1886, 10,221,255 dols.

The following is a tabulated statement of last year's production:—

Mineral production of Canada in 1905.

ENGLISH PATENTS.

Steel; Impts. in the conversion of iron into ——. R. Simpson, Swansea. From D. I. R. Simpson, Johannesburg, Transvaal. Eng. Pat. 5817, March 20, 1905.

THE molten iron is run by means of a trough from a blast-furnace into a self-contained converter moving on rails to the desired point, and provided with tuyères, and with means for receiving and discharging the metal, or else the metal is run continuously through a shallow ladle provided with an overflow arrangement, a blast of air being forced through the metal during its passage through the ladle.—A. G. L.

Steel; Manufacture of a substance to be used for the improvement of inferior qualities of ——. G. L. Hoffmann, Berlin. Eng. Pat. 13,141, June 26, 1905.

SEE Fr. Pat. 355,786 of 1905; this J., 1905, 1239.—T.F.B.

Iron; Manufacture of foundry pig ——. C. Henning, Mannheim, Germany. Eng. Pat. 23,592, Nov. 16, 1905. Under Int. Conv., Nov. 17, 1904.

IN order to produce homogeneous low-carbon cast-iron from cast-iron and steel, the steel (40 per cent.) is first melted with cast-iron (60 per cent.) in a cupola furnace and the product cast into pigs (foundry pig iron) which can then be easily melted with a further quantity of pig-iron (60 to 70 per cent.).—A. G. L.

Gold; Apparatus for separating particles of —— or other more or less precious metals or substances from the gangue or material with which they are associated. G. Moore, London. Eng. Pat. 25,116, Nov. 18, 1904.

ON both sides of a long sloping framework are placed two endless belts of canvas, india-rubber, or similar material, which pass over suitably arranged pulleys and move from the lower end of the framework towards the upper. Each belt has continuous flanges on each side so as to form a kind of trough, down which slime, &c., and water run from the upper end to the lower. A number of water-proof aprons of oil-cloth or india-rubber are arranged along the upper half of each belt, the lower ends of these aprons lying loosely on the belt, whilst the upper ends are fixed in position so as to force the fine material floating on the water into contact with the belts, which may be roughened, or have pieces of burlap, with or without wire-screens attached, fastened to them. Or, a second endless belt may lie loosely on the first one and travel with it, the second belt which consists of burlap and wire screen being longer than the first and passing over a separate drum at the upper end of the framework to admit of the surfaces of the two belts being cleaned separately. The returning (or under) part of each belt is raised considerably by being made to pass over a drum, covered with felt or other soft material, and placed near the centre of the frame.—A. G. L.

Zinc, nickel, cobalt and manganese oxides, and copper, arsenic, antimony, lead, bismuth, cadmium, and tin; Treatment of complex sulphide and oxidised ores for the recovery of ——. W. G. Rumbold, C. Patchin and J. W. Hughes. Eng. Pat. 2532, Feb. 8, 1905. XIIIA., page 325.

Metals; Extraction of —— from ores and waste materials. A. Gutensohn, London. Eng. Pat. 2619, Feb. 9, 1905.

THE powdered material, after roasting if necessary, is mixed with a flux consisting of a mixture of borate of manganese, carbon and fluorspar to which tar is sometimes added, and fused.—J. H. C.

Cupola furnaces. A. Baillot, Haybes, France. Eng. Pat. 10,312, May 16, 1905. Under Int. Conv., Dec 5, 1904.

SEE Fr. Pat. 349,036 of 1904; this J., 1905, 624.—T. F. B.

Blast-furnaces; Impt. in ——. Frodingham Iron and Steel Co., Ltd., and M. Mannaberg, both of Frodingham, Lincs. Eng. Pat 26,263, Dec. 16, 1905.

IN addition to the ordinary tuyères blowing into the

hearth of the furnace, one or more tuyères are provided and arranged so as to direct a blast against the bosh walls in order to burn away any deposited matter which might form a "scaffold."—A. G. L.

Ores; Process for treating finely granulated or pulverised ——. H. J. Haddan, London. From Fellner und Ziegler, Frankfort-on-Maine, Germany. Eng. Pat. 12,200, June 10, 1905.

See U.S. Pat. 801,144 of 1905; this J., 1905, 1113.—T. F. B.

Slag; Apparatus for pulverising blast-furnace ——. H. Colloseus, Berlin. Eng. Pat. 14,329, July 11, 1905.

See Fr. Pat. 356,379 of 1905; this J., 1906, 26.—T. F. B.

Metals; Separation of — from their ores. R. E. Saunders, and The S.O.S. Synd., Ltd., both of London. Eng. Pat. 21,839, Oct. 26, 1905.

Essentially the invention consists in allowing the powdered ore to fall vertically whilst subjecting it to the action of a horizontal current of air, the lighter gangue particles being thus separated from the heavier particles of ore. The current of air may be conveniently furnished by an exhaust fan working at the back of a casing open at the front. The ore falls from a hopper, placed on top and near the front of the casing, on to a number of inclined baffle-plates or on to a number of endless horizontal travelling bands arranged below each other, so that the material falls from one to the next. The casing may be divided by means of a longitudinal partition so as to enable the strength of the air current in the two parts to be varied.—A. G. L.

United States Patents.

Iron and steel; Apparatus for the treatment of ore for the manufacture of — therefrom. M. Moore, Melbourne, and T. J. Heskett, Brunswick, Vic. U.S. Pat. 814,557, March 6, 1906.

See Fr. Pat. 345,599 of 1904; this J., 1905, 32.—T. F. B.

Gold, silver, &c., Process of extracting ——. J. A. Comer, Los Angeles, Cal. U.S. Pat. 813,620, Feb. 27, 1906.

The crushed ore is treated with an alkaline solution of potassium cyanide, the solution is separated from the ore pulp and subjected to the action of compressed air, which is blown through it. After removing any sedimentary matter present in the solution, the gold, silver &c., are recovered electrolytically.—A. S.

Precious metals from ores, &c.; Process for the recovery of ——. J. A. Just, Pulaski, N. Y., Assignor to the Just Mining and Extraction Co., Syracuse, N. Y. U.S. Pat. 814,294, March 6, 1906.

The ores, especially silver and silver sulphide ores, are pulverised or granulated, then suspended in a solution containing an oxygen-yielding substance (nitre), treated with excess of sulphuric acid, and a current of air blown through. The mixture is heated until the solution is concentrated to one-half or less of its original volume, then diluted with acid or acidulated water to nearly its original volume, the acid solution separated from the sand and gangue, and the silver and gold separated from the acid solution, which latter is recovered for use over again.—A. S.

Metal-leaching process. T. B. Joseph, San Francisco, Cal. U.S. Pat. 814,452, March 6, 1906.

The invention relates to a process for the extraction of gold and silver, and consists in leaching the ore with an aqueous solution containing sodium cyanide, calcium hydroxide, barium dioxide, and ammonium bicarbonate, and simultaneously agitating the mixture with compressed air. —A. S.

Furnace; Roasting ——. T. F. Sheridan, Chicago, Ill., Assignor to Allis-Chalmers Co., Milwaukee, Wis. U.S. Pat. 814,238, March 6, 1906.

The invention relates to a roasting furnace with a hollow vertical shaft having hollow, horizontal "rake-arms" extending therefrom and communicating with the interior of the shaft. The hollow shaft and arms are filled with water, and a cooling medium is also circulated independently through pipes disposed in the hollow arms and communicating on the one hand with a supply-pipe in the shaft, and on the other, with the interior of the hollow shaft.—A. S.

Furnace; Roasting ——. F. Klepetko, New York. U.S. Pat. 814,297, March 6, 1906.

The furnace comprises a number of hearths through which passes a rotating, vertical, hollow shaft, from which hollow arms extend into the several hearths. A cooling medium, such as water, is introduced near the middle of the shaft, and is caused to circulate through the shaft and arms "vertically in parallel and in series, and radially in multiple," finally leaving the shaft at the opposite ends thereof.—A. S.

Furnace; Roasting ——. F. Klepetko, New York. U.S. Pat. 814,298, March 6, 1906.

The rotating, vertical, hollow shaft extending through the hearths of the furnace is divided longitudinally into a series of conduits, which, in turn, are divided by transverse partitions into compartments or chambers. From the shaft, hollow arms extend into the hearths. Cooling media are caused to circulate through the several conduits and the hollow arms attached thereto. (See preceding abstract).—A. S.

Furnace; Roasting ——. F. Klepetko, New York. U.S. Pat. 814,299, March 6, 1906.

See preceding abstracts. The shaft is divided by transverse partitions into chambers closed at top and bottom. By means of a feed-pipe passing through the partitions separating the chambers, a cooling medium (water) is fed simultaneously into the several chambers of the shaft, and, after circulating through the hollow arms projecting from the shaft into the hearths of the furnace, is discharged through an exhaust pipe provided with intake openings in the spaces between consecutive chambers.—A. S.

Cupola. F. N. Cline, Chicago, Ill. U.S. Pat 814,769, March 13, 1906.

The furnace comprises a metal-melting chamber lined with fire-clay, and a crucible mounted in a second chamber at a lower level than the melting chamber, the bottom of the latter having, at one side, a throat or passage, lined with fire-clay, which extends over the upper edge of the crucible. Flame is led into the second chamber around the crucible, passes over the top of the crucible, and through the throat into the melting chamber, the products of combustion escaping through a gas-discharge pipe leading from the bottom of the melting chamber opposite the throat. The molten metal flows by gravity from the melting chamber through the throat into the crucible. —A. S.

Tin or tin and lead; Process of recovering ——. J. C. Taliaferro, Baltimore, Md., Assignor to Continental Can Co., New York. U.S. Pat. 814,334, March 6, 1906.

Tin or tin and lead are separated from iron or steel by fusing the first-mentioned metals, adding sufficient lead to cause the iron or steel to float to the top of the mixture, skimming off the iron or steel, and separating the tin and lead from the skimmings by melting on charcoal.—A. S.

Copper separation; Process of ——. A. Elliott, Little-rock, Cal. U.S. Pat. 814,836, March 13, 1906.

Oxidised copper ores containing basic gangue are leached with a hot, non-acid solution of ferrous sulphate, air being passed through the solution during the leaching operation. From the resulting solution the copper is precipitated by means of iron, ferrous sulphate being regenerated.—A. S.

Agitating device [for metallurgical apparatus]. W. B. Devereux, Glenwood Springs, Colo. U.S. Pat. 815,272, March 13, 1906.

In a tank provided with means for decanting the liquid

contained in the same, a number of vertical shafts are disposed, on each of which a propeller rotates at a substantial distance above the bottom of the tank, and above the level to which the solid material of the charge will settle when the propellers are at rest.—A. S.

FRENCH PATENTS.

Furnace; Calcining ——. H. Howard. Fr. Pat. 358,977, Oct. 30, 1905.

A DRYING or heating chamber is constructed over the arch of a circular reverberatory furnace, and the ores are fed into this chamber before they pass on to the furnace proper, so as to utilise a great part of the heat which would be otherwise lost. A stream of cold air is supplied to the chamber through a regulator, and revolving rabbles are provided to stir up the ore and force it into a tube which contains a screw propeller whereby it is regularly fed to the furnace below.—J. H. C.

Bronze; Process of making ——. G. E. Buttenshaw. Fr. Pat. 359,080, Nov. 3, 1905.

SEE Eng. Pat. 792 of 1905; this J., 1906, 184.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 272.)

(*A.*)—ELECTRO-CHEMISTRY.

Electric glow lamps; Process of making a metallic connection between the light emitting bodies and the supply conductors of ——. H. Kuzel. Eng. Pat. 15,462, July 27, 1905. II., page 307.

UNITED STATES PATENTS.

Water; Process of decomposing —— by electrolysis. W. F. M. McCarty, Rocky Ridge, Md., Assignor to T. A. Darby, New York. U.S Pat. 813,105, Feb. 20, 1906.

METALLIC sodium or other alkali metal is added to water, which may have been previously acidified, the solution being subsequently electrolysed.—R. S. H.

Electrolytic apparatus. L. V. Scoyoc, Gilbert Station, Iowa. U.S. Pat. 813,844, Feb. 27, 1906.

THIS invention relates to an apparatus for the decomposition of water by electrolysis, and comprises a liquid-container and a liquid-supply for the same, together with a float valve, actuated by variations in the water level in the container, and supplying water to the latter so as to maintain a constant level. Receptacles for collecting the gases, with their open lower ends projecting below the water level in the container, have gas-bags arranged on their upper open ends. The receptacles for the gases have partitions provided with valve openings, and float valves in the receptacles acting in these valve openings regulate, by variations in the water levels, the discharge of the gases into the gas-bags. Electrodes are arranged in the container within the open lower ends of the gas-collectors. —B. N.

Decomposing water by electrolysis; Apparatus for ——. M. F. M. McCarty, Rocky Ridge, Md., Assignor to T. A. Darby, New York. U.S. Pat. 814,155, March 6, 1906.

THE electrolytic tank is divided from top to bottom by a partition into two chambers, the partition being provided near its lower end with a line of apertures, a glass tube being mounted in each aperture and extending into the respective chambers. An electrode is mounted in each chamber, and is connected with a suitable source of current supply, each electrode comprising a plate of suitable material extending approximately from side to side of the tank in order to present a large superficial area. Each electrode is bent inwards at its lower end, forming a terminal discharge portion extending at right angles to the body of the electrode, and located opposite and in line with all of the apertures and the ends of the glass tubes.—B. N.

Cells; Apparatus for feeding electrolytic ——. F. J. Briggs, Everett, Mass. U.S. Pat. 814,583, March 6, 1906.

THIS invention relates to a device for feeding cells in electrolytic apparatus, and comprises a tank of insulating material, divided by a central partition into two chambers on opposite sides of a standard which supports the tank on a pivot, the standard being in line with the partition. A spring is supported centrally by the standard, and extends longitudinally under the tank. Siphon pipes connect the interior of each chamber with the exterior, and are adapted to be connected with an outside cell. The tank supports a track which extends from one side of the pivot support to the other, this track consisting of two pairs of metallic rods, the rods in each pair being of unequal length, in line with each other and with their ends separated by small spaces. The longer rod in each pair is adjacent to the shorter, and overlaps the longer rod in the opposite pair. The supports for the outer ends of the rods are attached to the siphon pipes. A freely-moving ball on the track is adapted to roll from a position on one side of the pivot support to the other, and means are provided at opposite ends of the track for limiting the movement of the ball. A water supply is located directly over the central partition when the tank is level. The track forms a portion of an electrical circuit, containing a register, whereby, as the tank is tilted down in either direction, the supply of water enters the chamber which is tilted up, and the stream of water which is siphoning out through the opposite chamber is broken, thus breaking any electrical circuit which is passing through the stream. When the rolling ball passes over the centre of the track where the longer rods overlap, it completes the electrical circuit of which the rods form a part, and registers the emptying of one of the chambers.—B. N.

FRENCH PATENTS.

Hydrogen peroxide; Electrolytic preparation of ——. Consortium für Elektrochem. Ind. G.m.b.H. Fr. Pat. 358,806, Oct. 24, 1905.

THIS invention relates to a process for the electrolytic preparation of hydrogen peroxide from persulphuric acid percarbonates, perborates or other analogous substances which may be easily obtained by electrolysis of pure solutions at an elevated temperature in the absence of catalytic agents, the platinum which passes into solution during the electrolysis being extracted by the use of a special cathode or by chemical means. The hydrogen peroxide is extracted from the electrolytic solution by solvents, such as ether or ethyl acetate, or by rapid distillation at a low temperature in a vacuum, the extracted solution being again submitted to electrolytic oxidation. —B. N.

Electric arcs; Process and apparatus for internally throwing up luminous —— especially for the treatment of gases or mixtures of gases by movable luminous electric arcs. A. J. Petersson. Fr. Pat. 359,113, Nov. 4, 1905. Under Int. Conv., Nov. 7, 1904.

THIS invention relates to a process of producing a luminous electric arc between electrodes placed in an electric

circuit, by closing the trajectory of discharge by means of an arc on another circuit, the latter arc being brought over the former by magnetic or electro-magnetic influence. The arcs are first established between the electrodes where the minimum separation is relatively small, and the deviation of these arcs is produced by electrodynamic forces, so as to bring them over the electrodes where the amount of minimum separation is relatively great. Several forms of laboratory furnaces are described, furnished with pairs of electrodes, one or more pairs of electrodes being separated to only a slight extent, and placed in a circuit or circuits so that the arcs are established by an expenditure of energy relatively small. Those arcs are deviated as before mentioned towards the pairs of electrodes which are separated to a greater extent, and which are placed in circuits in which the arcs are only established by expenditure of energy relatively great. —B. N.

(*B.*)—ELECTRO-METALLURGY.

Lithium; Preparation of metallic ——. O. Ruff and O. Johannsen. Z. Elektrochem., 1906, **12**, 186—188.

The authors electrolyse fused lithium bromide containing 10 to 15 per cent. of lithium chloride, and attain a yield of about 80 per cent. of the theoretical. The electrolytic vat is of the type designed by Muthmann, Hofer and Weiss (this J., 1902, 412—413), the salt being fused in a water-cooled metal receptacle by means of an arc and subsequently submitted to electrolysis in the same vessel. A current of 100 ampères at 10 volts is employed, the anode being a carbon rod, whilst the cathode consists of two iron rods of 4 mm. diameter. The metal, which separates at the cathode in the fused condition, is removed from time to time with a shallow iron spoon and poured off from the solidifying salt. The mixture of salts recommended has a good electrical conductivity and low fusing point (about 520° C.), and has proved the most suitable for the purpose. When it is desired to prepare pure metallic lithium, the addition of salts of the other alkali metals is not to be advised. Electrolysis of a mixture of lithium and potassium chlorides yielded a metal containing 5 per cent. of potassium, whereas the metal prepared as described above, contained only 0·17 per cent. of sodium. The melting point of lithium has been determined as 180° C.—R. S. H.

English Patents.

Copper electrotypes; Manufacture of —— and apparatus therefor. S. O. Cowper-Coles, London. Eng. Pat. 4668, March 6, 1905.

The frames containing the wax or other impressions to be electrotyped are mounted in a vat and serve as cathodes. The anodes are mounted on a central rotating frame, and are perforated to admit of circulation of the electrolyte. The latter is admitted at the bottom of the vat, and is projected by centrifugal force through the perforations over the surface of the cathode. In this way all air bubbles are removed and a deposit of copper free from pin-holes can be obtained at a rapid rate of deposition with a current density of from 500 to 1000 ampères per square foot. —R. S. H.

Electro-plating; Apparatus for ——. L. Potthoff, Brooklyn, New York. Eng. Pat. 6790A, March 30, 1905.

A tumbling barrel suitable for containing small articles to be plated, and provided with the necessary mechanism for rotation, is arranged in a vat. Anodes are provided both inside and outside the barrel, and cathodes lead the current to the work to be plated. The essential part of the process consists in the arrangement whereby, when the barrel is rotated in one direction, the articles are retained and submitted to the deposition, whereas, when the direction of rotation is reversed, they are discharged from the apparatus.—R. S. H.

Ore separators; Magnetic ——. C. Leon, London. From Maschinenbau Anstalt Humboldt, Kalk, Germany. Eng. Pat. 19,525, Sept. 27, 1905.

See Fr. Pat. 357,216 of 1905; this J., 1906, 80.—T. F. B.

United States Patents.

Electroplating Apparatus. L. Potthoff, Flushing, N.Y. U.S. Pat. 806,835, Dec. 12, 1905.

See Eng. Pat. 6790A of 1905; preceding these.—T. F. B.

Matte; [Electrolytic] Method of treating ——. W. M. Johnson, Hartford, Conn. U.S. Pat. 814,049, March 6, 1906.

The copper-nickel matte is subjected to the action of hot dilute sulphuric acid, whereby nickel is dissolved and sulphuretted hydrogen liberated, the latter being subsequently converted into sulphuric acid, whilst a residue consisting in part of copper sulphide is left. The nickel is recovered from the solution, the bath being maintained neutral by the addition of nickel hydroxide, which is added proportionately to the amount of metal separated at the cathode. The residue, consisting partly of copper sulphide, is roasted so as to form the oxide, which is then treated with sulphuric acid, and the solution of copper sulphate is electrolysed, using insoluble anodes of lead, in order to separate a portion of the copper, the gases from the roasting operation being simultaneously passed into the liquid. The solution is again used for extracting the roasted residue, and then again electrolysed until the presence of nickel interferes with the deposition of the copper. Further quantities of copper are afterwards obtained by deposition on rotary cathodes. The spent electrolyte is finally used for treating a fresh quantity of the matte.—B. N.

[Zinc] Smelting process; Electrical ——. W. M. Johnson, Iola, Kans. U.S. Pat. 814,050, March 6, 1906.

This invention relates to a smelting process for recovering volatile metals such as zinc, which consists in interposing between a relatively low-resistance charge, containing low-grade ore mixed with low-resistance carbon, and a furnace wall or hearth, a high-resistance charge containing high-grade ore mixed with high-resistance carbon, and also a layer of inert material, such as finely-divided carbon, acting as the electrodes. The furnace wall and hearth are thus protected from the low-grade ore during the passage of an electric current through the charges, the latter being so arranged as to secure a substantially even temperature within the furnace.—B. N.

Metallurgical process [Zinc]. F. T. Snyder, Oak Park, Ill. U.S. Pat. 814,810, March 13, 1906.

Zinc sulphide ore is mixed with carbon and slag-forming materials, and the mixture electrolysed in a bath of fused slag, in absence of air, at a temperature above the volatilising point of zinc, one of the electrodes being of carbon. Zinc and sulphur in the form of vapour are produced at the electrodes, and the sulphur combines with the carbon to form carbon bisulphide. The zinc vapour and carbon bisulphide are collected separately, the former being condensed, whilst the latter is conveyed to an engine where it is combined with oxygen in order to develop mechanical power which is used to drive an electric generator to supply current for the electrolysis.—A. S.

Amalgamating process [Electrical ——]. H. A. Thomas, Assignor to Dry Amalgamation Co., Chicago, Ill. U.S. Pat. 814,814, March 13, 1906.

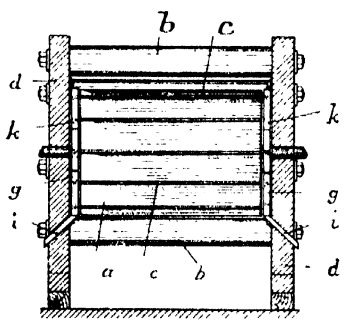
A "thin continuous sheet or layer of pulverised ore" is fed through a body of insulated and electrostatically-charged mercury, whereby the precious metals are amalgamated and removed from the ore.—A. S.

Iron ore; Process of [electrically] smelting ——. P. L. T. Héroult, La Praz, France, Assignor to Soc. Electro-Metall. Franç., Froges, Isère, France. U.S. Pat. 815,016, March 13, 1906.

The invention relates to a process of smelting iron ore by the aid of an electric current. Carbon is introduced at the base of the charge of ore in quantity sufficient to produce the chemical reactions necessary, and is protected from the action of the carbon dioxide generated during the smelting process. A mixture of carbon monoxide and carbon dioxide is formed, of gradually increasing

richness in carbon dioxide as the gases rise to the point at which the reduction of ore practically ceases. At this point oxygen is introduced, whereby the carbon monoxide is further oxidised, and the heating effect in the furnace increased.—A. S.

Iron ore ; Process for [electrically] smelting ——. P. L. T. Héroult, La Praz, France, Assignor to Soc. Electro-Metall. Franç., Froges, Isère, France. U.S. Pat. 815,293, March 13, 1906.



The invention relates to a process of electrically smelting iron ore. The ore is introduced at the top of the furnace, and means are provided for protecting the carbon from carbon dioxide generated during the smelting. The mixture of carbon monoxide and carbon dioxide produced, rises through the charge, and at a point above the level at which carbon monoxide is formed, nozzles are provided, through which oxygen is introduced in order to convert the carbon monoxide into carbon dioxide, and thus increase the heating effect in the furnace.—A. S.

Ore-separator ; Wet magnetic ——. F. J. Odling and W. Jamieson, Melbourne, Australia. U. S. Pat. 813,113, March 13, 1906.

The apparatus comprises a frame in which are mounted magnetic pole-pieces having V-shaped tips, and extending horizontally, but separated by an air-gap. A vibrating guiding-table or apron on to which a mixture of the ore and water is fed, extends through the air-gap between the poles, and an endless band of non-magnetic material travels longitudinally adjacent to the tip of the upper magnetic pole-piece. Means are provided for forming a film or coating of water on the travelling band. By the vibration of the table, the mixture of ore and water is caused to flow below the upper magnetic pole ; the magnetic particles are attracted by the latter and are retained by the "water web" produced by the co-operation of the film of water on the travelling band and the water mixed with the ore. This "water-web" carries the magnetic particles forward and delivers them at the side of the pole-pieces.—A. S.

French Patents.

Ores ; Electro-magnetic separator of ——. W. Wurmbach. Fr. Pat. 350,423, Dec. 24, 1904.

This invention relates to an electro-magnetic separator in which the chambers of separation are separated from rotating magnets by intermediate non-magnetic walls, *g*. The magnetic system consists of a series of horizontal cores, *b*, which may be excited magnetically, and these are disposed around the chambers of separation, *k*, the poles of the same sign being united at their ends by vertical polar pieces, *d*. The latter are made in the form of segments extending over three-fourths of a circle, so that there is an opening in which the magnetic field is not produced. An armature, *a*, with radial conducting plates, *c*, turns within the poles, *d*, and cores, *b*, and the armature is provided with a coil for exciting the magnets. The non-magnetic particles fall and are delivered through *i*, while the magnetic particles are carried round and expelled through the openings of the polar pieces, *d*, where the magnetic field is broken.—B. N.

Zinc and its alloys ; New process for electro deposition of ——. Dr. G. Langbein and Co. Fr. Pat. 358,622, Oct. 18, 1905.

The process of electro-deposition of zinc upon metallic objects is improved by the addition of urea to the bath. Double salts which are readily soluble are formed, and a high current density can be maintained without resulting in the production of a spongy deposit.—R. S. H.

Metallisation of articles of celluloid, horn, &c. ; [Electrical] Process of ——. L. Schwob and G. Hébert-Dilette. Fr. Pat. 359,001, Oct. 30, 1905.

This invention relates to a process of gilding or nickel-plating articles of celluloid, horn, &c., by plunging them into a bath of silver for about 1½ hours, the bath being made up as follows : 50 grms. of "Seignet salt" ("potassium tartrate") are dissolved in a litre of water ; 100 grms. of silver nitrate are dissolved in 55 grms. of ammonia, and added to 1 litre of water ; 50 grms. of each solution are added to 1 litre of water. The articles coated with silver are then placed in an ordinary gold or nickel-plating bath, and a current of electricity passed to deposit the metal.—B. N.

Furnace ; Electric ——, *for the reduction of metals and alloys and particularly of aluminium, silicon, magnesium, chromium, &c.* E. Viel. Fr. Pat. 359,042, Oct. 31, 1905.

The oxides to be treated are intimately mixed with a calculated amount of carbon or other reducing agent and passed in small quantities, but continuously, by means of a screw propeller, between two horizontal or conveniently inclined and highly excited electrodes contained within a crucible lined with carbon, whereby the metal or alloy is reduced and liberated, and falls upon an inclined bed, whence it may be removed as required.—J. H. C.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 273.)

Manihot Glaziovii ; Fatty oil of the seeds of ——. G. Fendler and O. Kuhn. Ber. Dtsch. pharm. Ges., 1905, **15**, 426—429. Chem. Centr., 1906, **1**, 768—769.

One hundred of the seeds of Manihot Glaziovii weigh 53 grms., of which 39·5 grms. consist of shells or husks, and 13·5 grms. of kernels. The kernels contain 5·18 per cent. of water and 35·20 per cent. of substances soluble in ether ; and the husks, 6·66 per cent. and 1·31 per cent. respectively ; the whole seeds contain 9·94 per cent. of fat. The oil examined was prepared from the whole seeds by percolation with ether. It was greenish-yellow in colour, had an odour resembling that of olive oil, and a somewhat bitter, acrid taste. It was soluble in ether, chloroform, benzene, carbon bisulphide, acetone and amyl alcohol, insoluble in absolute alcohol and glacial acetic acid ; with petroleum ether it gave a turbid solution. The oil became turbid at 4° C., but was not solid at —17°C. It had the sp. gr. 0·9258 at 15° C. ; acid value, 2·18 ; saponification value, 188·6 ; Reichert-Meissl value, 0·7 ; iodine value, 137·0 ; unsaponifiable matter, 0·9 per cent. ; glycerol, 10·6 per cent. ; refractometer reading at 40° C., 62·9. The fatty acids consisted of 89·03 per cent. of liquid, and 10·97 per cent. of solid acids. They had the following characters : Sp. gr. at 25° C. ; 0·8984 ; m. pt., 23·5° C. ; solidifying pt., 20·5 ; acid value, 197·6 ; saponification value, 200·1 ; mean molecular weight, 280·7 ; acetyl-acid value, 179·9 ; acetyl value, 20·7 ; iodine value, 143·1 ; iodine value of liquid fatty acids, 163·6 ; m. pt. of solid fatty acids, 54° C.—A. S.

Oleic acid series ; Some new acids of the ——. G. Ponzio. Gaz. chim. ital., 1906, **35**, 569—572.

From 100 grms. of stearic acid, 21 grms. of 2.3-oleic acid

(this J., 1904, 942), m. pt. 59° C., can be obtained. The latter acid, when allowed to stand for several days in contact with bromine, is converted into 2·3-dibromostearic acid, m. pt., 72° C. When heated in a sealed tube at 100° C. with hydrobromic acid in glacial acetic acid solution, β-bromostearic acid, m. pt. 54° C. is formed, which, on heating with alcoholic potassium hydroxide solution under an inverted condenser, yields β-hydroxystearic acid. $CH_3(CH_2)_{14}.CH(OH)CH_2.COOH$, m. pt. 89° C., moderately soluble in warm alcohol and chloroform, slightly soluble in petroleum ether and soluble in ether.

The 2.3-dihydroxystearic acid,

$$CH_3(CH_2)_{14}.CH(OH).CH(OH).COOH,$$

obtained by oxidising 2.3-oleic acid in dilute potassium hydroxide solution with the theoretical quantity of a 1 per cent. solution of potassium permanganate at 0° C., crystallises from ethyl acetate in prisms, m. pt. 126° C., soluble in most organic solvents, and also to some extent in warm water. On oxidising 2.3-oleic acid with twice the quantity of potassium permanganate mentioned above, and without cooling, palmitic acid is produced. (Compare this J., 1888, 442.)—A. S.

Chlorine gas; Use of —— under moderate pressures in the chemical arts. [*Chlorine-proof oil*]. E. A. Asheroft. VII., page 314.

Cocoa-nut fat in butter; Process for the detection of ——. H. P. Wijsman and J. J. Reijst. Z. Unters. Nahr. Genussm., 1906, **11**, 267–271.

THE authors propose a simple method for the detection of cocoa-nut fat in butter, based on Jensen's work as to the precipitation of certain of the volatile fatty acids by silver nitrate solution (this J., 1905, 1025). The sample of butter-fat is treated according to the usual method for the determination of the Reichert-Meissl value, and to the 110 c.c. of distillate, 40 c.c. of N/10-silver nitrate solution are added. After filtering, and washing the precipitate, the excess of silver nitrate is titrated with N/10-sodium chloride solution. The number of c.c. of N/10-silver nitrate solution used up in precipitating some of the volatile acids, is increased by one-tenth (correction for solubility of the silver salts) and is called the first "silver value." A second determination is then carried out in an exactly similar manner, except that 300 c.c. of distillate are collected, water being added to the distilling flask as required. The number of c.c. of N/10-silver nitrate used in this case, when increased by one-fifth, gives the second "silver value." In the case of mixtures containing cocoa-nut fat, the 110 c.c. of distillate in the first determination is not sufficient to hold the whole of the caprylic acid in solution, and some of the latter, therefore, escapes precipitation by the silver nitrate, whereas, in the second determination, the whole of the caprylic acid will be dissolved in the 300 c.c. of distillate, and a higher "silver value" will be obtained. In the case of pure butter-fat, on the other hand, less caprylic acid is present, and the "silver value" will be the same in the second determination as in the first, or even somewhat smaller, owing to the solubility of the silver precipitate in the larger volume of distillate. It was found that even with only 5 per cent. of cocoa-nut fat in a sample of butter, the second "silver value" was higher than the first, whilst in the case of pure butters, even two with abnormal Reichert-Meissl values, the second "silver value" was the same as or lower than the first.—A. S.

Fats; A reagent in the chemistry of ——. [*Naphthalene-stearosulphonic acid*]. F. Twitchell. J. Amer. Chem. Soc., 1906, **28**, 196—200.

THIS acid, the preparation of which has been described previously (this J., 1900, 254), may be used for the separation of stearic and palmitic acids from oleic and linolic acids in tallow and other fats. When a melted mass of mixed fatty acids is treated with a little naphthalene-stearosulphonic acid, the liquid fatty acids present, become slightly soluble, and by simply treating with water can be washed out of the mixture, partly in solution, but mainly as emulsion. Five grms. of the mixed fatty acids are treated with about 1 c.c. of a 10 per cent. aqueous solution of naphthalene-stearosulphonic acid and a little dilute sulphuric acid (containing about 1·25 per cent. of sulphuric acid). After thoroughly mixing the mass, a further 20 or 30 c.c. of the dilute acid are added and the mixture allowed to settle. The whole is then filtered, an oily layer rising to the surface being first brought on to the filter. The solid portion is washed with the sulphuric acid until the filtrate is no longer turbid. From 80 to 90 per cent. of the liquid fatty acids will have been removed by this treatment, and the remainder may be separated by repeating the process once or twice. The crystalline mass on the filter is finally washed with water and dried. It is important that the right quantity of sulphuric acid be used and the temperature during the separation should be a little above the melting point of oleic acid.

Naphthalene-stearosulphonic acid possesses catalytic properties and has the power of hydrolysing fats. Other fatty sulphonic acids, with the exception of stearosulphuric acid, also act as catalytic agents. The action of these sulphonic acids may be explained as follows:—They are soluble in water and their aqueous solutions dissolve fatty bodies, acting like soap solutions. At the same time they are acids which are electrolytically dissociated to a high degree, and the hydrogen ions set free, cause the hydrolysis of the portion of the fat dissolved.—W. P. S.

Linoleic Acid. U.S. Customs Decision, Feb. 20, 1906

LINOLEIC acid was held to be dutiable at 25 per cent. *ad valorem* under paragraph 1 of the tariff, as an "acid not specially provided for." The analysis showed the sample to be composed of 14·73 per cent. of linseed oil, and 85·27 per cent. of linoleic acid. The assessment of duty at 20 c. per gall. of 7½ lb. as "linseed oil" under paragraph 37 was overruled. [T.R.] R. W. M.

Wool lubricant; A ——, soluble in water. J. W. Riep and G. H. Bauer. Eng. Pat. 7231, April 5, 1905. V., page 310.

Oils and fats; Apparatus for heating ——. F. P. y Garcia, Madrid. Eng. Pat. 12,784, June 20, 1905.

CLAIM is made for an apparatus for heating oil or fat by means of the heat produced by a chemical reaction. The apparatus, intended for use with a solid substance termed "Sosca" (a mixture of lime and sodium carbonate), consists of two cylinders the inner of which is perforated all over. The "Sosca" is placed in this vessel and is treated with water introduced from a separate chamber. There is also a lid in the form of a funnel screwed on to the top of the receptacle to carry off the vapours produced in the reaction. When the apparatus is charged, it is introduced into the vat containing the solidified fat.

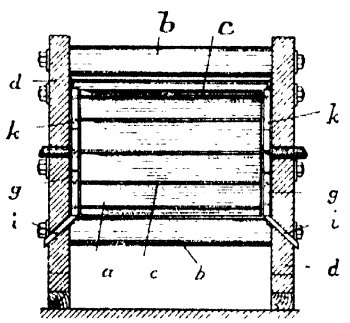
richness in carbon dioxide as the gases rise to the point at which the reduction of ore practically ceases. At this point oxygen is introduced, whereby the carbon monoxide is further oxidised, and the heating effect in the furnace increased.—A. S.

Iron ore ; Process for [electrically] smelting ——. P. L. T. Héroult, La Praz, France, Assignor to Soc. Electro-Metall. Franç., Froges, Isère, France. U.S. Pat. 815,293, March 13, 1906.



The invention relates to a process of electrically smelting iron ore. The ore is introduced at the top of the furnace, and means are provided for protecting the carbon from carbon dioxide generated during the smelting. The mixture of carbon monoxide and carbon dioxide produced, rises through the charge, and at a point above the level at which carbon monoxide is formed, nozzles are provided, through which oxygen is introduced in order to convert the carbon monoxide into carbon dioxide, and thus increase the heating effect in the furnace.—A. S.

Ore-separator ; Wet magnetic ——. F. J. Odling and W. Jamieson, Melbourne, Australia. U. S. Pat. 813,113, March 13, 1906.

The apparatus comprises a frame in which are mounted magnetic pole-pieces having V-shaped tips, and extending horizontally, but separated by an air-gap. A vibrating guiding-table or apron on to which a mixture of the ore and water is fed, extends through the air-gap between the poles, and an endless band of non-magnetic material travels longitudinally adjacent to the tip of the upper magnetic pole-piece. Means are provided for forming a film or coating of water on the travelling band. By the vibration of the table, the mixture of ore and water is caused to flow below the upper magnetic pole ; the magnetic particles are attracted by the latter and are retained by the "water web" produced by the co-operation of the film of water on the travelling band and the water mixed with the ore. This "water-web" carries the magnetic particles forward and delivers them at the side of the pole-pieces.—A. S.

(*C.*)—INDIA-RUBBER, Etc.

Quebrachite; Presence of —— in the latex of Hevea brasiliensis. A. W. K. de Jong. Rec. trav. chim. Pays-Bas, 1905, **25**, 48—49. Chem. Centr., 1906, **1**, 818.

The alcoholic solution obtained on coagulating the latex of *Hevea brasiliensis*, when evaporated on the water-bath, yields crystals of quebrachite, $C_6H_{11}O_5.OCH_3$, m. pt. 190°—191° C., easily soluble in alcohol, acetone and ether; $[\alpha]_D^{28°} = -80{\cdot}2°$. Quebrachite is a sugar which was first isolated from quebracho bark (*Aspidosperma quebracho*) by Tanret (this J., 1890, 202).—A. S.

India-rubber; Influence of chalk and of moisture on the vulcanisation of ——. R. Ditmar. Gummi-Zeit., 1905, **20**, 579—580.

Guayule rubber was vulcanised with 10 per cent. of sulphur and varying percentages of chalk for 50 minutes at 145° C., and the products tested mechanically. In one series of experiments all the materials were carefully dried, in a second series the rubber was allowed to retain its natural moisture, amounting to 14·5 per cent. In either case the breaking strength increased with the amount of chalk, up to 40 per cent. incorporated; the extensibility showed a maximum at about 16 per cent of chalk in the experiments with dry rubber, whilst in those with moist rubber a maximum occurred at about 12 per cent., and another at about 24 per cent. It is proved experimentally that the chalk goes into perfect colloidal combination with the rubber and does not react with the sulphur. On vulcanisation with low percentages of chalk, the products are very porous, owing to the escape of steam; from this the author concludes that chalk acts as a binder of moisture in the process of vulcanisation.—W. A. C.

Rubber; Process of devulcanising ——. M. Körner. Fr. Pat. 358,635, Oct. 18, 1905.

The rubber is heated for a considerable time at a high temperature (130°—150° C.) with benzene or other solvent, in presence of water or steam. In a modification of the process the extract obtained by heating with the solvent is heated along with water or steam, preferably under pressure.—C. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 275.)

Lime spots in vegetable-tanned coloured leather. W. Eitner. Gerber, 1906, **32**, 78—79.

The author has often been troubled, in the dyeing of kips, with the appearance of spots upon the grain. The cause appears to be due to the use of hard water. A similar defect is often met with in the case of glacé leather. In the latter leather the cause is that the free sulphuric acid of the alum, not having been washed out, acts on the lime from the hard water to form calcium sulphate, which is precipitated in the grain of the leather, thus preventing the dyestuff from penetrating readily. In the case of vegetable-tanned leather, the spots are formed in the "scudding process," by the calcareous water used, but they are not easily seen until the finished article is produced. Such lime deposits, which are unevenly distributed, are very difficult to remove, even by severe mechanical treatment.

For their removal an acid de-liming agent should be used, so as to convert the lime into a soluble form. The following acids are employed to this end:—Hydrochloric, lactic, acetic, and formic acids.

To remove lime stains from vegetable-tanned goods before dyeing, wash the tanned goods till soft, and then place in a bath of 2 per cent. hydrochloric acid and move for two hours. After this process the goods are to be well washed with water in the drum, and are then ready for dyeing.—H. Bn.

Lactic acid [Commercial]; Analysis of ——. M. Philip. XXIII., page 339.

Nutgall extract. U.S. Customs Decision.

The United States Circuit Court of Appeals, Jan. 25, 1906, decided that extract of nutgalls is not dutiable under paragraph 1 of the tariff, either directly or by similitude, as "tannin or tannic acid" at 50 c. per lb. This decision affirms one of the United States Circuit Court and reverses that of the Board of General Appraisers, whose latest decision held to the duty under paragraph 1. A previous decision of the Board made nutgall extract dutiable at ¼ c. per lb., and 10 per cent. *ad valorem*, as "nutgalls advanced in value or condition," under paragraph 20. The Court points to an unbroken line of Treasury Decisions for 26 years on nutgall extract, none of which considered the assessment of duty as "tannin," though tannin was especially named in all the tariff laws covering this period. The Treasury Department, Feb. 24, 1906, acquiesced in this decision on the advice of the Attorney-General, and directed the assessment of duty at ¼ c. per lb., and 10 per cent. *ad valorem*, under paragraph 20, as "nutgalls advanced in value or condition."

Skins or hides; Process and apparatus for extracting grease and oil from ——. H. Brewer and J. T. Hardy, Bulwell, Notts. Eng. Pat. 10,437, May 18, 1905.

The wet skins, after liming and salting, are placed in heaps to press the superfluous moisture from them. They are then placed in a rotating drum or tumbler and subjected to the action of deodorised petroleum or other grease solvent and afterwards to the action of warm salt water to wash away the petroleum, grease, &c. The revolving drum has the shape of a double cone and is mounted on hollow spindles. One of the latter enters directly into the drum, whilst the other is closed to the interior of the drum except through a pipe which enters the middle or widest part of the vessel. This pipe is closed by a valve, which, when opened, allows the solvent to pass out of the drum into a collecting vat. The spindle opening into the drum allows the final salt wash to be injected. The drum is provided with a reversing gear, and is fitted with suitable openings. The treatment of the skins takes about four hours or longer.—W. P. S.

Hides; Process of treating ——. F. J. Oakes, New York. Eng. Pat. 24,487, Nov. 27, 1905. Under Int. Conv., Dec. 12, 1904.

French Patents.

Tanning and colouring materials; Automatic extractor for ——. L. F. Jury. Fr. Pat. 358,783, Oct. 7, 1905.

The material to be extracted is placed in a cylindrical vessel provided with suitable openings, a water-gauge, &c., and is there subjected to the action of water or of a weak extract resulting from a previous operation. The concentrated extract is pumped up to a receiver, and, when this is full, a ball-float diverts the current to a second receiver, where the subsequent weaker extracts are collected. The first receiver is divided into two similar compartments, so that they can be used alternately, and the second receiver into a number of compartments, each provided with a ball-float, which, when the compartment is full, causes the stream of liquid to be delivered into the next one, and so on. As the ball-floats rise they open valves at the bottom of the compartments and allow the weak extract to flow through the vessel containing the material. The liquid is heated on its way to the vessel by passing through a condenser into which the steam, arising from a concentrating apparatus, is conducted. The extract from the first receiver is further evaporated in this concentrator, in order to obtain a syrupy or dry product.—W. P. S.

Chrome leather; Process for waterproofing ——. A. Flöring and M. Lenneberg. Fr. Pat. 358,894, Oct. 27, 1905.

The dry leather is immersed for one hour in a bath of melted paraffin or ceresin containing from 5 to 30 per cent. of colophony, carnauba wax, beeswax, Japan wax or the like.—W P. S.

Leather; Process for the manufacture of artificial ——. J. B. Granjon and J. F. J. Berchet. Second Addition, dated Oct. 14, 1905, to Fr. Pat. 343,704, June 4, 1904 (this J., 1904, 1036).

If the leather be intended for use as machinery belts, the cardboard sheets described in the original patent are replaced by strips of strong canvas. Metallic threads or wires are placed between the strips, and to avoid fraying at the edges, the canvas may be made in the form of a tube (like a fire-hose) before treating with the asphalt, &c. It is finally rolled flat while still hot.—W. P. S.

Glue; Process for making ——. W. S. Sadikoff. Fr. Pat. 358,859, Oct. 25, 1905.

Fat and mineral matters are removed from the substances from which the glue is to be made, and the mass then treated with dilute sodium hydroxide solution (from 1 to 3 per cent. in strength). The still alkaline mass is now boiled for 10 minutes with a 1 per cent. aqueous solution of monochloracetic acid, filtered, and the glue precipitated from the solution by means of magnesium sulphate. The glue is finally washed with cold water as usual.
—W. P. S.

Metallisation of articles of celluloid, horn, &c.; [Electrical] Process of ——. L. Schwob and G. Hébert-Dilette. Fr. Pat. 359,001, Oct. 30, 1905. XIB., page 323.

Casein and similar substances; Conversion of ——, *into plastic products.* L. Collardon. Fr. Pat. 359,073, Nov. 2, 1905.

The casein is mixed with a 20 per cent. solution of viscose (in a suitable solvent) at a temperature of 60° C. Substances which harden the casein and decompose the viscose may be added during the operation. In place of viscose, other cellulose compounds may be employed.—W. P. S.

Nitre; Analysis of ——. R. Bensemann. XXIII., page 337.

English Patents.

Fertilisers; Manufacture of —— *and apparatus therefor.* J. Crone, D. C. Taylor, and F. Williams, St. Helens, Lancs. Eng. Pat. 5618, March 17, 1905.

Waste animal substances, such as shoddy, hide and leather scraps, and the like, are delivered in a moist state, into a horizontal cylindrical vessel, adapted to be rotated on hollow trunnions, and enclosed within a chamber of refractory material, heated by a series of grates and flues. The trunnions are connected with fixed end boxes, having removable doors, through which the charge is introduced. A perforated pipe, supplying sulphuric acid of about 115° T., is led into the cylinder through the end boxes, and as far from the axis of rotation as convenient, so that the acid is sprayed evenly over the contents of the vessel as the latter rotates. Shoddy supplied to the apparatus should contain at least 40 per cent. of water. An exhausting fan is connected to the boxes, and delivers into a gas condensing tower. Pits are provided to receive the material when it it discharged. (Reference is made to Eng. Pat. 6101 of 1904, this J., 1905, 203.)—E. S.

Peat; Apparatus for treating ——, *particularly for making manure.* C. H. J. van Haeften, The Hague. Eng. Pat. 10,023, May 12, 1905.

Rapid disintegration of peat is effected by treating it with water containing ammonia, which also brings into solution constituents insoluble in water alone. The apparatus claimed for this process comprises a battery of closed vessels, in which the peat is lixiviated, reservoirs for water and for ammonia solution, with means for heating or cooling, and an air-pump which draws air through the reservoirs and the battery. The ammonia is drawn forward with the air, and when the water is saturated, the ammonia may be returned to its own reservoir by reversing the current.—C. A. M.

Yeast [Fodder or fertiliser]; Treating —— *to render it suitable for commercial purposes.* F. Gothard. Eng. Pat. 13,834, July 5, 1905. XVII., page 331.

XVI.—SUGAR, STARCH, GUM, Etc.

(*Continued from page 277.*)

Diffusion waste-waters [beetroots]; Return of the —— *to the battery.* H. Claassen. Z. Ver. deut. Zuckerind., 1906, 260—278.

The author describes the advantages derived from working a diffusion battery by returning all the weak draining and pressing waters, usually run to waste, these waters taking the place of a corresponding quantity of fresh water in working the battery. By this means, the question of disposing of these waters, which are liable to become noxious, is removed, and a greater or smaller quantity of sugar can be left in the pressed slices according to fluctuations in the value of the sugar for fodder, or for recovery. These waters are not allowed to remain outside the battery for more than a few minutes, and are pumped back into the next diffuser, together with the necessary quantity of fresh water before they have had

time to cool. With rational working and with the extraction of the same amount of sugar as in the old process, it was found that the purity of the juice was slightly increased by the new process, because fresh water dissolves more non-sugar than the waste-waters. Thus the pressed slices not only contain all the extractive substances previously lost in the waste waters, but also a greater quantity of non-sugar. An advantage is only obtained by the new process if the whole of the waste waters be returned to the battery, and these wastes, *viz.*, drainage waters and press waters, should be mixed together and not passed in separately, according to the quantity of sugar present in the different fractions. If the temperature of the waste waters be maintained at the necessary high degree (75° C.), no deleterious changes need be feared in them. Lastly, if irregularities in extraction occur owing to abnormal beets or faulty supervision, no absolute loss can take place as in the old system, there is merely an alteration in the distribution of the sugar between the diffusion juice and the pressed fodder slices.—J. F. B.

Carbohydrates and organic acids and bases; Solubility and specific rotatory power of some —— in pyridine and other solvents. J. G. Holty. J. Physical Chem., 1905, **9**, 764—779. Chem. Centr., 1906, **1**, 917.

The solubility in pyridine at 26° C. of the substances examined is given in the following table:—

Substance.	Grms. in 100 parts of solution.	Substance.	Grms. in 100 parts of solution.
Levulose	18·49	Erythritol	2·50
Malonic acid	14·60	Lactose	2·18
Dextrose	7·62	Strychnine	1·23
Sucrose	6·45	Mannitol	0·47
Galactose	5·45	Propyl tartrate .	Soluble in all proportions.

The rotatory powers of the different solutions were compared with those of aqueous solutions of equal concentration. In the case of sucrose, dextrose, levulose and galactose, the specific rotation was greater in pyridine than in aqueous solution; with the other substances examined, the reverse was the case. The rotatory power of solutions of sucrose in pyridine was altered considerably by addition of benzene, carbon bisulphide, acetone, nitrobenzene or chloroform.—A. S.

Hydrazones and osazones of some α-diketones and reducing sugars; Thermochemistry of the ——. P. Landrieu. Comptes rend., 1906, **142**, 580—582.

The heats of combustion and of formation of the phenylhydrazones and phenylosazones derived from diacetyl, benzil, benzoin, and from the seven commoner reducing sugars, are given in tabular form, in addition to the heat disengaged in the preparation of these compounds from the corresponding diketones and sugars.—E. F. A.

Sugar production of Germany. Bd. of Trade J., March 22, 1906.

According to statistics published in the "Reichsanzeiger," the quantity of raw sugar produced in Germany during the period from 1st Sept., 1905, to Feb. 28 last, being the first six months of the 1905-6 sugar campaign, was 2,068,211 metric tons, as compared with 1,333,279 metric tons during the corresponding months of 1904-5. The quantity of refined sugar produced increased from 786,043 metric tons during the six months September, 1904, to February, 1905, to 903,019 metric tons during the six months September, 1905, to February, 1906. The total quantity of beets used during the first half of the present campaign was 15,726,425 metric tons, as compared with 10,071,211 metric tons during the corresponding months of 1904-5.

The total output of sugar (raw and refined) during the period September, 1905, to February, 1906, expressed in terms of raw sugar, was 2,295,349 metric tons, as compared with 1,510,461 metric tons in the corresponding months of 1904-5. [T.R.]

English Patent.

Lixiviating and washing sugar and other substances; Apparatus for ——. A. Hinze, Rositz, Germany. Eng. Pat. 5663, March 17, 1905.

See U.S. Pat. 793,133 of 1905; this J., 1905, 835.—T. F. B.

United States Patent

Carbonating apparatus for liquids. P. C. Haan, New Brunswick, N.J., Assignor to J. D. Pickard, East Orange, N.J. U.S. Pat. 813,883, Feb. 27, 1906.

The apparatus consists of a containing tank for the liquid and gas under pressure, and is provided with a float for governing the inlet of liquid, this float carrying a nozzle which sprays the liquid upwards through an atmosphere of compressed gas. The inlet for distributing and diffusing the gas comprises a vertical perforated spiral coil with spiral deflecting plates attached thereto; above the coil is placed a casing containing a series of corrugated deflecting plates surmounted by a stratum of porous material, to cause the union of liquid and gas held in the containing tank, by bringing them into intimate contact under pressure.—J. F. B.

French Patent.

Seaweed; Treatment of —— for the extraction of mineral and organic chemical substances. Mme. Laureau *née* J. H. Laureau. Third Addition, dated Oct. 14, 1905, to Fr. Pat. 352,069, March 6, 1905. VII., page 315.

XVII.—BREWING, WINES, SPIRITS, &c.

Barley; Relation between protein contents and condition of endosperm of ——, also method of testing barley. E. Jalowetz. Allg. Z. Bierbrau. u. Malzfab., 1906, **41**; Woch. f. Brau., 1906, **23**, 126—127.

The author proposes a new method for ascertaining rapidly whether a barley is rich or poor in protein according to the steeliness or mellowness of the endosperm. The barley is covered with a 40 per cent. solution of formaldehyde in a long-necked flask, nearly closed with a cork. The flask is heated in a boiling water-bath for 30 minutes; the grain is washed three or four times with cold water, pressed between blotting paper, and at once tested with the usual grain cutter. In all cases the cut surface possesses a gummy edge, inside which the section may show either a very strikingly chalky surface or a pronounced steely appearance. Between these two extremes, two or three intermediate conditions may be recognised, even by an inexperienced observer. The formaldehyde combines with the albuminoids of the grain, and the compound thus formed so influences the course of the reaction that the corns, rich in nitrogen, remain steely, whilst those poor in nitrogen are modified by the treatment and become mealy. This test distinctly reveals the fact, previously ascertained by analysis, that the corns in the lower part of the ear are less rich in nitrogen than those of the upper part of the same ear. It also eliminates the difficulty of distinguishing between "apparent" steeliness, which is harmless, and the permanent steeliness which is accom-

panied by a high protein content. The author has found in one case that the mealy corns contained 1·16 per cent. of nitrogen; the half-steely corns, 1·59 per cent.; and the steely corns, 1·70 per cent. If all the corns in a sample are mealy or almost mealy, the percentage of protein lies within the prescribed limits for a brewing barley; if all the corns are steely or half-steely, the barley is rich in protein. Mixed results indicate that the barley is not uniform as regards the protein contents, and is a mixture of two types, an observation which could not be made by a determination of the nitrogen on the whole sample in the usual way.—J. F. B.

Barley with abnormally high protein content; Malting of ——. T. Hajek. Z. ges. Brauw., 1906, **29**, 171—172

THE author conducted malting experiments with an abnormal barley having the following composition:—Moisture, 12·9; extract on air-dry grain, 62·9; and protein, 17·27 per cent. This barley was indistinguishable by external observations from normal brewing barley containing 10—11 per cent. of protein. The barley was steeped for 93 hours, being left six hours without water on the second and third days and three hours on the fourth day. The couch was piled 10 ins. high and was spread over the whole floor on the second day to a depth of about 5 ins. Germination was conducted in the cool as far as possible and lasted eight days. In spite of a somewhat restricted steeping and all possible precautions for cool germination, the temperature on the floor rose to 22·5° C., showing that barleys rich in protein have a natural tendency to get hot on the floor. The malt was divided into two portions, one being kilned on the Munich system and the other as in the preparation of Pilsener malt at a low temperature.

The malt possessed a low extract value corresponding to the high protein content. The enzyme contents were also high, as was shown by the fact that even the Munich malt required only ten minutes for complete saccharification, and by the high ratio of maltose to total extract. The proportion of soluble albuminoids was high, higher in the pale malt than in the dark, owing either to the coagulation of albumin or the destruction of proteolytic enzymes at the higher temperature of curing. The colour of the wort from the pale malt corresponded to one of the Vienna type, whereas an ordinary barley treated in the same way should have given a paler wort of the Pilsener type. This illustrates the function of the albuminoids in contributing to the colouring matters of malt. The modification of both malts was very bad, and was such as to make them quite unsuitable for brewing purposes. The author considers that these experiments fully confirm the current views as to the difficulty of producing good malts from barleys which are rich in protein.—J. F. B.

Malt [Distilleries and yeast factories]; Temperature necessary for the destruction of injurious organisms on ——. W. Henneberg. Z. Spiritusind., 1906, **29**, 93—94.

THE really injurious organisms in a distillery are the "wild" lactic acid bacteria, whilst in a yeast factory the mycoderma yeasts are also harmful. These organisms cause a large increase of acidity in the main mash, bad attenuation, bad yield of yeast and instability and flocculation of the yeast. In cases where malt is used cold, after the saccharification, in order to prevent foaming fermentation, there is very great danger of infection by the organisms occurring on the malt, unless these are first destroyed at a moderate heat. This destruction can be effected without crippling the diastase by heating the mash at 55° C. for 15 minutes. The author has found that this treatment is sufficient to prevent the subsequent development of all the non-sporulating organisms, amongst which the above-mentioned injurious species are included. The temperatures required to kill the principal organisms present in distillery mashes are as follow:—Mycoderma yeasts are killed in five minutes at 60° C., or in one minute at 65° C.; distillery yeasts lose their power of reproduction at 58° C., and are killed in one minute at 68°—70° C.; the acetifying *B. Xylinum* is killed in one minute at 50° C.; the cultivated lactic acid bacterium, *B. Delbrücki*, is killed in five minutes at 65° C., and in one minute at 72·5° C.; the "wild" lactic acid bacteria are killed in one minute at 66° C. It is quite unnecessary, even with the worst malts, to employ high temperatures for preventing infection. The injurious organisms both in the yeast mash and the main mash are killed during saccharification, and a re-heating at the saccharification temperature of 62° C. for half an hour after acidification of the yeast mash is sufficient to ensure the absence of these organisms. A higher temperature will cripple the diastase without producing a more efficient sterilisation, since the spore-bearing bacteria can withstand even a temperature of 100° C for a considerable time.

The main difficulty in sterilising mashes in the above manner on an industrial scale lies in the difficulty of ensuring that all the organisms are submitted to the desired temperature. Particles of the mash get splashed on the walls and edges of the tuns, and the organisms on these parts escape the action of the heat and are washed back afterwards into the mash.—J. F. B.

Diastatic enzymes; Influence of certain alkaloids and their salts on the activity of ——. H. E. Goebel. Z. Spiritusind., 1906, **29**, 85.

THE author has tested the influence of various alkaloids on the velocity of conversion of starch by Taka-diastase. The majority of the free alkaloids either retarded the conversion of starch into maltose or left it unaffected. The salts of the alkaloids retarded the diastatic action at the ordinary temperature, but accelerated it at 50° C. It is remarked, however, that neither the alkaloids nor their salts cause any alteration of the enzyme itself. Certain alkaloids, such as morphine and the hydrochlorides of atropine and pilocarpine, had a slight accelerating influence on diastatic action. Caffeïne, codeïne, atropine, nicotine, quinine and the hydrochlorides of codeïne and caffeïne had a slight retarding influence. Quinine hydrochloride, strychnine and its hydrochloride, veratrine and morphine hydrochloride had no influence at all.—J. F. B.

Yeasts; Part played by cysts of Glœosporium in the origin of ——. P. Viala and P. Paccotet. Comptes rend., 1906, **142**, 518—520. (See this J., 1906, 277.)

THE cysts of some species of *Glœosporium* form under certain conditions endogenous spores, which in favourable nutrient media, when freed from the cysts, develop to a mycelium of filaments and short elements with buds. These cysts bear the same relationship to the ordinary form of the fungi as the sporulating yeasts do to the budding forms.—E. F. A.

Yeast culture; New method for pure ——. H. Wickman and H. Zikes. Mitt. Oesterr. Versuchss. und Akad. f. Brauind., 1905; J. Inst. Brewing, 1906, **12**, 163—164.

A FILM of gelatin is spread with a glass rod on a cover glass divided up into squares of 2 mm., and is allowed to solidify under a watch glass. The yeast is suspended in beer wort at a suitable dilution, and a drop of the liquid is taken up in a sterile capillary tube, which is then lightly touched on the surface of the gelatin so as to leave a trace of the liquid on each of the squares. The plate thus prepared is placed in a Böttcher's chamber or on a hollowed microscope slide, and is fixed by vaseline. If the dilution has been properly chosen, each drop should contain one cell which can grow on the gelatin surface, and the new cells all lie in one plane. The individual cells are found as easily as with Lindner's droplet culture method; the new cells after 24 hours can readily be counted; the colonies can easily be re-inoculated and the cultures are very lasting.—J. F. B.

Cane juice; Fermentation of ——. F. Watts and H. A. Tempany. West Ind. Bull., 1906, **6**, 387—393.

WHEN cane juice is allowed to ferment spontaneously, the liquid becomes markedly acid and assumes a yellow colour, whilst a dark scum rises to the surface, the juice being said to sour; pronounced alcoholic fermentation with vigorous evolution of carbon dioxide then sets in, resulting in the production of over 8 per cent. by volume of alcohol in the liquid and the

deposition of a sediment of yeast. Finally in course of time, with free access of air, acetification of the alcohol takes place in the ordinary manner, the colour of the liquid changes to a clear, dark red, and the so-called "cane vinegar" is produced. The authors have found that the preliminary acidification ("souring") of the juice takes place equally well in absence as in presence of air. The disappearance of sugar and, presumably, the formation of alcohol proceed much more rapidly when air is allowed free access to the juice than when it is excluded. A study of the acidification of sugar solutions by inoculation of the dark scum from cane juice led to the conclusion that the acid is produced by the oxidation of the sugar by bacterial action at the expense of oxygen derived from the sugar itself, but no corresponding reduction product of the sugar could be identified, though traces of a body crystallising in prismatic needles and which may be mannitol (Marcano, Comptes rend., **108**, 955; this J., 1889, 561) were always found on evaporation. The ratio of volatile acid to fixed acid produced during this preliminary acidification was about 1:2. The organism which produces this acidity forms a felt-like growth in saccharine media, consisting of long threads which break up after 48 hours into short rod-like bacterial forms. The addition of 2 per cent. of phenol to the juice inhibits the acidification of the sugar.—J. F. B.

Colour; Formation of —— by bacteria in saccharine nutrient media. A. Kossowicz. Zeits. landw. Versuchsw. in Osterreich, 1904, 404; Zeits. ges. Brauw., 1906, **29**, 166.

THE author has examined the coloration produced by various bacteria in a solution containing 3 per cent. of raffinose or sucrose, 0·25 of potassium dihydrogen phosphate, 0·005 of tricalcium phosphate, 0·25 of magnesium sulphate, 0·25 of diammonium phosphate, and 0·2 of ammonium chloride.

B. prodigiosum produces a lemon-yellow colouring matter which appears after two or three weeks, and goes into solution. Red colouring matters are formed by *B. lactorubefaciens* and *micrococcus agilis*. *B. synxanthum* produces a reddish-brown substance, the appearance and intensity of which depend, as is also the case with the colouring matters formed by yeasts, on the proportion of magnesium sulphate present. *B. fluorescens liquefaciens* produces a characteristic yellow fluorescent substance, whilst with *B. fluorescens putidus* a white deposit is formed. A yellow colour is also obtained with *B. fluorescens aureus* and *Sarcina liquefaciens*. *B. cyaneofuscus* forms a greyish-brown colouring matter, and *B. mesentericus fuscus* a pale-brown deposit appearing after from two to four weeks. *B. butyricus Hueppe* produces a pale yellow coloration after three or four weeks and develops butyric acid. After six or eight weeks, *B. coli commune* forms a distinctly yellow colouring matter. With the following bacteria pure white cultures are obtained, even after about four months growth:—*Spirillum Finkler-Prior, Streptococcus pyogenes, Micrococcus flavescens, Tyrothrix distorta, B. Freudenreichii, B. aerogenes, B. lactis aerogenes* and the bacterium of stable manure. The last three bacteria and also *B. synxanthum* ferment raffinose vigorously.—T. H. P.

Fermenting vessels of cement. A. Weber. Woch. Brau., 1906, **23**, 95.

THE author recommends the use of fermenting vessels of wired glass, the joints being made with pure cement, coated with "brewers' pitch" ("Bierlack") at frequent intervals of time. The cement is not affected in any way, even the small particles of cement adhering to the glass being unchanged either by the beer or by brushing. In large vessels the attenuation is from 0·2° to 0·3° greater than in smaller ones, but the taste of the beer is the same in the two cases. The use of large vessels, up to 180 hectol. capacity, is recommended on grounds of economy.

The lager vessels used by the author are constructed on the Monier system, the walls and bottom being of cement fitted internally with wired glass. These give very satisfactory results and effect great economy, since they require only half the cellar room, whilst the cooling plant may be diminished, and the pitching of the vessels omitted.—T. H. P.

Wines made from vines attacked by mildew; Chemical character of ——. E. Manceau. Comptes rend., 1906, **142**, 589—590.

WINE made from grapes attacked by mildew contains less alcohol, more total acidity and a higher proportion of nitrogenous organic matter, also more mineral constituents and less free tartaric acid than wine from the same vines treated with sulphur. Such wines have an abnormal chemical composition which gives them a peculiar flavour and renders them more liable to oxidation and attack by disease germs.—F. F. A.

Apple marc; Study of ——. W. D. Bigelow and H. C. Gore. J. Amer. Chem. Soc., 1906, **28**, 200—207.

APPLE marc, or the insoluble matter of the flesh of the apple, is composed mainly of parenchymous tissue and about 40 per cent. of it is rendered soluble by boiling with water. This water extract consists of one complex carbohydrate, a galacto-araban. The must of apples, when treated with several volumes of alcohol, invariably gives a gummy precipitate. This precipitate contains complex carbohydrates which are richer in galactan, relative to the pentosan content, than the hot water extract of apple marc. The same is true of the alcohol precipitate given by "second pressing" ciders. The treatment with boiling water decreases the yield of crude fibre and cellulose and at the same time gives a purer fibre and a purer cellulose.—W. P. S.

"Quick" vinegar process; Bacteriological investigations on the ——. W. Henneberg, Deut. Essigind, 1905, **9**, 393—395, 403—405, 410—412; Chem. Centr., 1906, **1**, 613—614.

BACTERIOLOGICAL examination of vinegar and beechwood shavings, taken directly from an acetifying chamber working normally, showed that the vinegar itself was almost free from bacteria, whereas the shavings contained enormous quantities of acetifying bacteria. The vinegar from a chamber which is working defectively is characterised by the presence of a relatively large quantity of bacteria. In a normal chamber the disposition of the acetifying bacteria in the fibres of the wood and their relatively great power of coherence prevent them being washed off by the vinegar which flows over the shavings. Plate cultures on unhopped wort-agar showed the presence in the vinegar of mycoderma yeasts, yeasts capable of developing fruity ethers and only a few bacteria. Cultures from scrapings from the beechwood shavings showed growths of hay bacilli, spherical bacteria and large quantities of mucus-forming acetifying bacteria. Samples from a defective chamber gave growths of infusoria, dematium, mycoderma yeasts and *B. xylinum*. Since even the normal chambers contain large quantities of organisms quite unconnected with the acetifying process, it is difficult to determine the condition of a chamber by bacteriological analysis of the vinegar, although the number of foreign organisms in a defective chamber is greater. It was not possible to conduct experiments with pure cultures; the author could only obtain cultures of groups of organisms, concentrated as regards acetifying bacteria, by cultivation under certain conditions of nutrition, acidity and temperature. Suitable media for this purpose are diluted beer wort, beer, grain mash and vinegar mash. *B. xylinum* was present in all the vinegar chambers examined and had no deleterious influence on the work of the chambers.

Experiments in the laboratory with "quick" vinegar bacteria concentrated by natural selection, showed that the acetifying process can be effected quite as well in the laboratory as in a properly prepared vinegar chamber, a vinegar containing 10—11 per cent. of acetic acid being obtained under favourable conditions.—J. F. B.

Cane molasses distillery; Chemical control of a ——. J. S. Gongora. Bull. Assoc. Chim. Sucr. et Dist., 1906, **23**, 884—891.

FOR controlling the work of the distillery the density and

the acidity of the wash in each tun should be determined before fermentation. After fermentation, determinations should be made of the proportion of alcohol in the fermented wash, the density of the residue after elimination of the alcohol by distillation, the proportion of unfermented reducing sugars and the acidity. Records should be kept of the volume and strength of the alcohol obtained in the distillery from each tun and the quantity of alcohol lost in the vinasses. The difference between the sum of these two values and the quantity of alcohol calculated from the analysis of the fermented wash corresponds to undetermined losses, any sudden rise in which indicates a leakage at some stage of the distillation. The initial gravity of the wash gives the weight of molasses taken into work. The difference between the initial gravity and the final gravity after elimination of the alcohol gives the quantity of sugar fermented; this value, added to the quantity of unfermented sugar, gives the total sugar submitted to fermentation. The quantity of alcohol in the fermented wash, calculated as per cent. of sugar fermented, gives an idea of the purity of fermentation. The proportion of unfermented sugar per cent. of the total sugar indicates the physiological condition of the yeast. When a rise of this ratio occurs under constant conditions of work, it points to degeneration of the yeast or inhibition due to the presence of traces of anti-fermentative substances or to deficiency of yeast nutrients. The difference between the acidity before and after fermentation in well-conducted work, should not exceed 0·2 grm. per litre, calculated as sulphuric acid. When this number increases, the yield of alcohol per cent. of sugar will decrease, and it will be necessary to cleanse and disinfect the tuns. The time required for the wash in each tun to ferment should be recorded, as an indication of the activity of the yeast.—J. F. B.

Spirit monopoly; Russian state ——. Bd. of Trade J., March 29, 1906.

The spirit monopoly has been extended gradually, and by the middle of 1904 its operations covered all the Provinces of European Russia (Finland excepted) and Siberia. Comparing the yield of the beer and spirit excise before the introduction of the monopoly with that of the beer excise and the spirit monopoly after the introduction of the latter, the results are as follows: Before introduction, 30·7 millions sterling; after introduction, 42 millions. Allowing for extra expenditure in connection with control, &c., the result shows an increased revenue of 9·83 millions. In 1904, the population of the districts served by the monopoly was 127 millions. There were 2,368 distilleries, 335 bottling establishments, 28,209 establishments for sale. The amount of spirits sold was 189 million galls., or less than 1½ galls. per head. There was a slight reduction of the consumption as compared with the preceding year, owing to the comparatively poorer harvest, and the diminished purchasing power of the population. The gross yield in 1904 was 57 million sterling, and the expenditure 16·7 million, giving a net yield of 40·3, or 683,000*l.* less than the preceding year. The expenses of production were nearly 400,000*l.* more than in 1903. The movable and real property possessed by the Crown in connection with the monopoly was valued at 10·7 millions sterling.

The returns are satisfactory to the Government exchequer, as the yields are nearly 10,000,000*l.* superior to those derived by the State from the spirit and beer excise before the introduction of the spirit monopoly. The net revenue has, however, fallen off as compared with that of the year preceding the returns now published, which relate to 1904. This is attributable to the inferior harvest of 1903, which diminished the purchasing power of the population, and also to increased cost of production. The introduction of the spirit monopoly resulted in increasing the Government revenues at the expense of the resources of the local administrations, and the increased profit of the State implies the withdrawal of funds from the local bodies, which were generally employed for purposes of local improvement and education. [T.R.]

English Patents.

Yeast [Fodder or fertiliser]; Treating —— to render it suitable for commercial purposes. F. Gothard, Burton-on-Trent. Eng. Pat. 13,834, July 5, 1905.

Fresh brewers' yeast is pulverised or granulated by rubbing through a series of fine screens, and is then mixed in a machine with some perfectly dry, water-absorbent material suited for the purpose to which the product is to be applied. Suitable materials are dried, such as spent hops or hop meal, malt dust, brewers' grains, oat bran, powdered chalk, garden soil or sawdust. The mixture is quickly passed into a sterilising vessel in which it is heated, with agitation, and is finally reduced to a condition in which it contains not more than 12 per cent. of moisture, the product being used either as a fodder or fertiliser.—J. F. B.

Evaporators for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, waste or spent dyes and the like, and concentrating the solids in the same; the evaporator being also applicable as a smoke washer; Impts. in ——. A. B. Lenflox and T. Mackenzie. Eng. Pat. 7962, April 14, 1905. XVIII*B.*, page 332.

United States Patent.

Distilled liquids; Process for ascertaining the origin of colouring matters present in ——. C. T. Marsh, Assignor to L. H. Weissleder. U.S. Pat. 813,728, Feb. 27, 1906. XXIII., page 338.

German Patent.

Mashes in fermentation industries; Material for use in facilitating the drawing-off of ——. D. Ernst. Ger. Pat. 163,801, Jan. 14, 1905.

In the manufacture of spirit and pressed yeast, malt germs, oat husks, chopped straw, chaff, &c., are added to the mashes to facilitate the drawing-off of the wort. The patentee claims the use of the threads (of the beard) of the maize-cob in place of the materials named.—A. S.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 280.)

(*A.*)—FOODS.

Milk treated with hydrogen peroxide; Note on ——. P. Adam. J. Pharm. Chim., 1906, **23**, 273—277.

Fresh and unboiled milk which has not been treated with hydrogen peroxide gives, in the presence of hydrogen peroxide, a red coloration with guaiacol solution and a blue coloration with *p*-phenylenediamine, and decolorises the Methylene Blue of Schardinger's reagent (this J., 1905, 47). The same milk, previously treated with hydrogen peroxide, gives colorations with guaiacol and *p*-phenylenediamine, but does not change the colour of Schardinger's reagent. If this treated milk be kept until the hydrogen peroxide has disappeared, it will still give, in the presence of hydrogen peroxide, the reactions with guaiacol and *p*-phenylenediamine, but no longer decolorises Schardinger's reagent, differing in the latter respect from fresh milk. From the above facts, the author concludes that the reducing enzyme present in milk is alone destroyed by hydrogen peroxide, and that the oxidising enzyme (not to be confounded with the oxydase) withstands the action of the peroxide for a considerable time.—W. P. S.

Cocoa-nut fat in butter; Process for the detection of ——. H. P. Wijsman and J. J. Reijst. XXIII., page 338.

Cocoa and chocolate; Detection of foreign substances in ——. F. Bordas and Touplain. XXIII., page 338.

ENGLISH PATENTS.

Animal tissues and mixtures of such tissues with other substances, and the products obtained thereby; Process of preserving ——. J. R. Hatmaker, Paris. Eng. Pat. 4351, March 2, 1905.

THE substances, such as fish, oysters, beef, and all kinds of animal tissue, either alone or mixed with other substances, are reduced to a pulpy condition, with the addition of water if necessary. The pulp is then exposed in the form of a thin layer or film upon a suitable surface heated to a temperature above 212° F. (see Eng. Pat. 25,563, of 1904; this J., 1905, 1249), and removed before it is injured by over-heating. The substances may be cooked, digested or seasoned before drying.—W. P. S.

Yeast [*Fodder or fertiliser*]; *Treating —— to render it suitable for commercial purposes.* F. Gothard. Eng. Pat. 13,834, July 5, 1905. XVII., page 331.

[*Milk*] *Separators; Impts. in centrifugal* ——. H. H. Lake, London. From Aktiebolaget Separator, Stockholm, Sweden. Eng. Pat. 19,209, Sept. 22, 1905.

THE invention relates to separators which are driven by a steam turbine. A regulating cover, or a separate chamber communicating with the separator, is connected by a float or an arrangement of balanced levers with the steam valve. When the level of the milk in the separator sinks, the supply of steam is cut off, but a by-pass allows sufficient steam to pass to keep the separator running at a low speed when it is empty.—W. H. C.

Fruit syrups or fruit extracts; Process for making concentrated ——. O. Volz, Berlin. Eng. Pat. 612, Jan. 9, 1906. Under Int. Conv., Jan. 10, 1905.

FRUIT juice of any kind is treated with chloroform, benzene, carbon tetrachloride, ether, carbon bisulphide or similar solvent, and the latter then separated. The chloroform extract is evaporated at a low temperature under reduced pressure, the residue is dissolved in alcohol, the solution cooled, filtered to remove vegetable fats and waxes, and the alcohol again distilled off under reduced pressure. The residue of aromatic substances obtained may be added to the extracted juice after the latter has been evaporated under reduced pressure to about one-twentieth of its volume. The original juice may be obtained from fruit which has been preserved by the addition of alcohol or by pasteurising.—W. P. S.

UNITED STATES PATENT.

Casein; Process of precipitating and preserving ——. H. V. Dunham, Bellows Falls, Vt., Assignor to Casein Co. of America, New Jersey. U. S. Pat. 814,594, March 6, 1906.

A SMALL percentage of boric acid is added to the acid used for precipitating the casein.—W. P. S.

FRENCH PATENTS.

Lupins; Preparation of meal from ——, *for food.* A. de Sousa Reis. Fr. Pat. 358,713, Oct. 21, 1905. Under Int. Conv., Dec. 1, 1904.

LUPINS contain a large proportion (about 50 per cent.) of albuminoids but their utilisation as a foodstuff is hindered by the presence of a bitter principle. According to the present patent the lupins are boiled in a solution of acetic acid and common salt, and then purified by systematic extraction with water until the bitter substance is removed. The seeds are finally decorticated, dried and ground to meal.—J. F. B.

Whey from skimmed milk; Preparation of ——. Deutsche Milchwerke. Fr. Pat. 358,965, Oct. 28, 1905.

Two hundred litres of skimmed milk are mixed with 20 litres of full milk and heated to a temperature of 80° C for 45 minutes. The milk is then cooled to about 25° C., mixed with 6·6 litres of a culture of lactic acid bacteria, and the whole kept at this temperature until the acidity rises to 3·5 or 3·6°. The mixture is now rapidly cooled to about 14° C., and kept at this temperature for a further three or four hours. It is then ready for use as a beverage. —W. P. S.

Alimentary materials; Preservation of ——, *by means of ozone.* H. J. Wessels de Frise. Fr. Pat. 359,037, Oct. 31, 1905.

THE articles, such as meat, eggs, fruits, beverages, &c., to be preserved, are placed in a chamber from which the air is withdrawn by means of a pump, a pipe being provided at the top of the chamber for this purpose. The air withdrawn is passed successively through a cooling and drying chamber, an ozonising apparatus and a sterilising chamber and is then returned to the bottom of the chamber containing the foods. A portion of the ozonised air may be forced by a pump through jets directly on to the joints of meat or into the latter. The chamber is hermetically closed, but suitable openings are provided for removing the articles of food as required.—W. P. S.

GERMAN PATENT.

Proteins; Process for the separation of true ——, *from their solutions, and from salts, extractive matters, albumoses and peptones.* Farbw. vorm. Meister, Lucius und Brüning. Ger. Pat. 164,762, March 4, 1905.

ALBUMINOUS solutions are treated with a small quantity of alcohol, insufficient to produce a precipitate or turbidity, and the proteins are then separated by addition of an excess of acid or alkali. Or, the albuminous solutions are treated with an alcoholic solution of caustic soda or caustic potash, without producing a precipitate, and the proteins are then separated from the alkaline solution by the addition of acid.—A. S.

(*B.*)—SANITATION; WATER PURIFICATION.

ENGLISH PATENTS.

Clinker from refuse destructor furnaces; Treatment of ——. J. A. Brodie, Liverpool. Eng. Pat. 7521, April 10, 1905.

THE clinker is removed from the destructor furnace and at once introduced into a blast-furnace situated adjacent to the destructor. If needed, fuel may be added and also from 5 to 10 per cent. of lime or other flux. The products of combustion of the blast-furnace are led into the flue of the destructor or into a steam generating furnace. The material after treatment in the blast-furnace is suitable for road foundations, concrete or paving blocks.—W. P. S.

Evaporators for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, waste or spent dyes and the like, and concentrating the solids in the same; the evaporator being also applicable as a smoke washer; Impts. in ——. A. B. Lennox, Newcastle-on-Tyne, and T. Mackenzie, Glasgow. Eng. Pat. 7962, April 14, 1905. (See also Eng. Pats. 13,227 and 18,488 of 1904; this J., 1905, 811, 982.)

THE evaporator consists of a series of chambers, with openings in the baffle—or partition—walls between them, the whole being provided with a floor slanting upwards, and communicating at one end with a flue from a boiler, by way of an opening that can be closed by a damper, and at the other end with a chimney. The liquid to be evaporated is sprayed into the chambers, and any portion of the liquid that remains unevaporated drains away, together with any solid matter in the flue gases, through openings in the bottom of each partition, and runs down over the damper into a tank fitted with a strainer or filter to clarify the liquid, which can then be returned to the spraying devices. The communicating openings in the baffle-walls are of chequered brick or iron work, with an open area equal to that of the flue, and may be arranged at different levels so as to distribute the hot gases in passing from one chamber to another. The sloping arrangement of the apparatus enables a fan to be dispensed with when the chimney draught is good, but a fan may be provided in the chamber next the chimney, if necessary.—C. S.

Sewage and other similar sludges; Treatment of ——. [*Recovery of fatty substances*]. F. M. Spence, H. Spence and P. Spence and Sons, Ltd., Manchester and R. Ockel, Lower Walton, Cheshire. Eng. Pat. 8347, April 19, 1905.

THE nearly or completely solidified sludge cake, yielded by curdling or otherwise treating the sewage, is subjected to the action of a sufficient quantity of mineral acid, preferably sulphuric acid, to liberate the fatty acids from the mineral matters present. The amount of acid to be added is ascertained by a preliminary experiment on a small quantity of the sludge cake. Sufficient acid must be added to give a yield of fatty acids free from iron, alumina or other soaps. The acidified cake is then prepared for treatment with suitable solvents. (See also Eng. Pat. 23,640 of 1904; this J., 1905, 1080.)—W. P. S.

Water-purifying apparatus. J. J. Krüger, Copenhagen. Eng. Pat. 24,435, Nov. 25, 1905.

THE water to be purified is forced by suitable means through a water motor or turbine and is then conducted by a pipe to a measuring device, such as a tipping bowl, or paddle-wheel, situated at the top of a tank. The latter is provided with an outlet for the purified water and with a sludge cock. A reagent tank is placed at the bottom of the tank on the outside, and is provided with a stirrer and a pump, both worked by the water-motor. The pump raises the chemical solution up to a small receiver adjacent to the tipping device. This receiver is provided with an overflow and an arrangement, such as a movable pipe or valve actuated by levers from the tipping vessel or water-wheel, so that predetermined quantities of the chemical solution are delivered to the water before it enters the main tank.
—W. P. S.

UNITED STATES PATENT.

Water-purification system. J. F. Wixford, St. Louis, Mo. U.S. Pat. 814,634, March 6, 1906.

THE plant consists of a settling-basin and a delivery-well connected by a conduit near the bottom of the well. A pipe delivers a supply of reagent from a tank into a conduit entering the top of the well and a second pipe delivers lime-water from a lime tank into the conduit at a point nearer the well. Both pipes enter the conduit at such a distance from the well that the chemicals may be thoroughly mixed with the water before it enters the well. The reagent and lime tanks are provided with a supply of water.—W. P. S.

FRENCH PATENT.

Boiler water; Apparatus for the chemical examination of —— while the boiler is in operation. A. Schmitz. Fr. Pat. 359,046, Nov. 2, 1905. Under Int. Conv., Nov. 3, 1904.

SEE Eng. Pat. 22,621 of 1905; this J., 1906, 195.—T. F. B.

(*C.*)—DISINFECTANTS.

FRENCH PATENT.

Antiseptic soap; Manufacture of ——. M. Martens. Fr. Pat. 359,061, Nov. 2, 1905. Under Int. Conv., Nov, 14, 1904.

A SOAP containing "lysol" is claimed, and is obtained by adding a certain quantity of cresol to the alkali used in making the soap.—W. P. S.

GERMAN PATENTS.

Disinfectant from chloronaphthalene and soap; Process of preparing a ——. L. Schwabe. Ger. Pat. 163,663, Oct. 13, 1903.

OLEIC ACID is treated with dry chlorine until an increase of about 50 per cent. in weight is attained; 100 parts of the product are dissolved in 223 parts of 30 per cent. caustic potash solution, and heated until it is soluble in water. In this solution is dissolved 124 parts of the product obtained by chlorinating naphthalene with dry chlorine until it has increased 40—50 per cent. in weight, and removing the hydrochloric acid formed. The final product is stated to be soluble in water, and to contain 70 per cent. of chloronaphthalene calculated on the weight of oleic acid used. (Compare Eng. Pat. 4950 of 1893; this J., 1894, 271.)—T. F. B.

Disinfectant fluids; Process of preparing ——. L. Schachtel. Ger. Pat. 164,793, Feb. 25, 1904.

SOLUTIONS possessing considerable disinfectant properties are obtained by dissolving α- or β-naphthol, or a mixture of the two, in alkali carbonate solutions. The disinfectants may also be prepared in solid form by simply mixing the components. The best proportions are equal weights of naphthol and alkali carbonate: increase of the latter increases the solubility of the product, but diminishes its antiseptic properties. Such disinfectants are stated to be more effective than those prepared from naphthols and alkali hydroxides, and possess the advantage over other phenolic disinfectants of being non-poisonous and odourless.—T. F. B.

Paper making apparatus; Impts. in —— for effecting the separation of sand, metal and other impurities from the pulp. J. Macnaughton, Edinburgh. Eng. Pat. 23,399, Nov. 14, 1905.

SEE U.S. Pat. 813,984 of 1906; following these.—T. F. B.

Cellulose [*Viscose*]; *Apparatus for filtering and pumping or regulating the flow of solutions of* ——. C. F. Topham, Kew Gardens. Eng. Pat. 5766, March 18, 1905.

THE apparatus consists of a support connected with the main viscose supply, and provided with pivot joints maintaining in position the filter, the pump and the nozzle arm, all being clamped together and bored internally so that there is a direct passage from the viscose main to the squirting nozzle. The filter consits of two plates clamped together and provided on their internal faces with projections between which the filtering medium is firmly held, passages being provided for the viscose to pass between the projections. On the discharge side of the filter the supporting plate has a hole covered with an elastic diaphragm, which is distended by the pressure of the filtered viscose when the filter is working freely, but which collapses when the filter fails to pass more viscose than the pump is drawing away. The filtered viscose is drawn away by a plunger pump constructed without an inlet valve, a recess being provided beneath the plunger in which the viscose is trapped by the plunger. At the bottom of the recess is the delivery valve, closed by a spring, which requires a higher pressure to open it than the pressure of the viscose entering the pump. The difference in pressure is overcome by the work of the plunger on the column of viscose above the valve. The delivery valve can either be wholly removed for cleaning or can be loosened to such an extent that a rush of viscose sweeps any accumulated dirt through a passage to the outside, opened by the operation of loosening the valve. After passing the delivery valve the viscose is delivered to the nozzle arm, an air chamber in the form of a bottle being clamped against an opening in the side of the delivery tube to equalise the flow.—J. F. B.

Collodions and cellulose solutions; Pumps for supplying —— to filters and drawing apparatus. L. Desmarais, G. Morane, and M. J. A. Denis, Reims, France. Eng. Pat. 6783, March 30, 1905. Under Int. Conv., April 26, 1904.

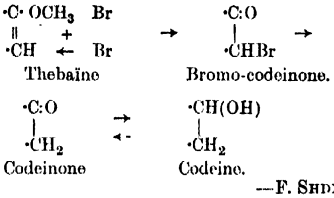
(*Continued from page* 284.)

Cinchona bark [and kola nuts] ; Cause of the red coloration of ——. A. Tschirch. Schweiz. Woch. f. Chem. u. Pharm., 1905, **43**, 125—126.



It has been noted that when fresh kola nuts are sliced, the cut surfaces turn red ; but if the seeds are previously kept in water at 60°—80° C. for a short period, no red colouring follows on cutting them. The formation of "kola-red" is, therefore, attributed to the presence of a hydrolytic ferment or an oxydase. The author observed, when in Java, that freshly removed cinchona bark is free from red colour when first stripped from the tree, but after 65 seconds exposure to the air, the surface turns red. It was found, however, that no red colour appeared when the cut branches were immersed for 30 minutes in water at 80° C., or when they were exposed to steam at the same temperature for a like period. When twigs of the living tree were bent down into a vessel of water at 80° C., and kept immersed for half an hour, again no reddening of the bark occurred when it was removed. If, however, the twigs, instead of being heated in water, were exposed to dry heat at 80° or 100° C. in an oven, reddening subsequently took place. The red colour would, therefore, appear to be due to the action of an enzyme on a glucotannoid, by which either "cinchona-red" itself, or a body which is converted into "cinchona red," is formed.—J. O. B.

Thebaine. M. Freund. Ber. 1906, **39**, 844—850.

The author has succeeded in converting thebaine into codeine. The following formula was proposed for thebaine in a previous communication (Ber., 1905, **38**, 3236):—

On treating thebaïne in chloroform or glacial acetic acid with bromine, the hydrobromide of a monobrom-addition product is obtained, and this, after recrystallising from dilute alcohol, yields fine leaflets melting at 197°—198° C. are obtained. This substance is the hydrobromide of bromo-codeinone, $C_{18}H_{18}BrNO_3$, HBr, H_2O. It contains one methoxyl group, and one methyl group attached to the nitrogen atom. If the hot alcoholic solution of this substance be treated with ammonia, the free base separates in clusters of needles melting at 156°—157° C., with decomposition. The base does not form a methiodide and is readily soluble in chloroform, but insoluble in water and caustic alkali. The bromine probably adds itself to the bridged ring, where it splits the methyl from the methoxyl group. The free base forms an oxime, $C_{18}H_{18}(OH)NO_2(:N.OH)$, which is free from bromine and soluble in dilute alkali. After recrystallising from alcohol, it melts at 272°—273° C. On reducing bromo-codeinone with iron filings and dilute sulphuric acid, codeinone, melting at 185° C., is produced, and this codeinone is identical with the codeinone obtained from codeine.

—F. Shdn.

Piperazine benzoate and salicylate. A. Astruc. Bull. Soc. Chim., 1906, **35**, 169—171.

The benzoate and salicylate of piperazine are obtained as crystalline precipitates on mixing 2 mols. of the acid with 1 mol. of the base in alcoholic solution. Piperazine benzoate, $C_4H_{10}N_2(C_6H_5.COOH)_2$, is a white anhydrous salt, crystallising in glistening plates, which volatilise without melting at 120° C. At 15° C. it dissolves in 15 parts of water, 16·3 parts of 90 per cent. alcohol, and 46·4 parts of absolute alcohol. It is acid to phenolphthalein. Piperazine salicylate, $C_4H_{10}N_2(C_6H_4.OH.COOH)_2$, separates in the form of fine white needles, which volatilise at 160° C. without fusion. At 15° C. it dissolves in 90 parts of distilled water, 200 parts of 90 per cent. alcohol, and 450 parts of absolute alcohol. It is acid to phenolphthalein.—F. Shdn.

"Pois de Java" ; Chemical investigation of ——. E. Kohn-Abrest. Comptes rend., 1906, **142**, 586—589

The grains from "Pois de Java" a species of *Phaseolus lunatus* (see Dunstan and Henry ; this J., 1903, 1255), yield hydrogen cyanide on maceration with water. The author has determined quantitatively the amount of hydrogen cyanide liberated after maceration with water, and subsequent boiling with hydrochloric acid in eight varieties. The amounts vary from 0·528 to 1·638 grms. per kilo. Cold dilute hydrochloric acid only liberates very small quantities of hydrogen cyanide—E. F. A.

Nerol ; Preparation of pure ——. H. von Soden and W. Treff. Ber., 1906, **39**, 906—914.

Crude nerol obtained from oil of petitgrain, purified by calcium chloride, was converted into the diphenylurethane. This was fractionally recrystallised from light petroleum or methyl alcohol. The geranyl-diphenylurethane separates first, melting at 81°—82° C., and from the mother liquors, neryl-diphenylurethane is obtained, melting at 52°—53° C. From 100 parts of crude urethane, 63 parts of pure neryl-diphenylurethane were separated. From this, pure nerol, $C_{10}H_{18}O$, was obtained. It is a colourless oil, possessing a delicate, fresh rose smell. The sp. gr. at 15° C. is 0·8813 ; b. pt. at 755 mm. 224°—225° C. ; at 25 mm. 125° C. Optical rotation, *nil*. A crystalline tetrabromide of nerol, $C_{10}H_{18}OBr_4$, is obtained by adding the calculated amount of bromine to a carefully cooled solution of nerol in chloroform. On evaporating, and recrystallising the residue from ethyl acetate and light petroleum, long silky needles, melting at 118°—119° C., are obtained. Geranyl-diphenylurethane gives pure geraniol, with the following constants :—Sp. gr. at 15° C., 0·8825 ; optical rotation, *nil* ; b. pt. at 3 mm., 94° C., at

25 mm. 129°—130° C.; at ordinary pressure, 229°—230° C. The tetrabromide after recrystallising from ether and light petroleum, melts at 70°—71° C.—F. Shdn.

Coumarin from m-cresol. K. Fries and W. Klostermann. Ber., 1906, **39**, 871—875.

Homologues of coumarin were produced by the Pechmann method from *m*-cresol, the methyl group in the meta position favouring the reaction. 4-*Methylcoumarin*, $C_{10}H_8O_2$, was prepared by heating *m*-cresol and malic acid with concentrated sulphuric acid. On crystallising from dilute alcohol, white needles or tablets melting at 128° C. are obtained. The compound smells strongly of coumarin, and is soluble in most organic solvents. It dissolves in aqueous sodium hydroxide on boiling, from which the greater part of the coumarin is precipitated by carbon dioxide. 2.4-*Dimethylcoumarin*, $C_{11}H_{10}O_2$, is obtained from *m*-cresol and acetoacetic ester. On crystallising from alcohol, short white needles melting at 132° C. are obtained. It is soluble in most organic solvents and in a boiling solution of caustic alkali. 1.2.4-*Trimethylcoumarin*, $C_{12}H_{12}O_2$, is obtained from *m*-cresol and methylacetoacetic ester. After crystallising from alcohol, the product has the form of fine glistening needles, melting at 114° C. It possesses no coumarin-like odour, and is readily soluble in most organic solvents. It is only slowly dissolved by hot caustic alkali solution.—F. Shdn.

Calcium and strontium iodomercurates. A. Duboin. Comptes rend., 1906, **142**, 573—574. (See this J., 1906, 283.)

The author has obtained the compounds, $CaI_2,HgI_2,8H_2O$; $SrI_2,5HgI_2,8H_2O$; and $SrI_2,HgI_2,8H_2O$ crystallising in transparent needles.—E. F. A.

Antimony tartrate. J. Bougault. Comptes rend., 1906, **142**, 585—586.

The author prepared a well characterised antimony tartrate, $C_4H_3O_6Sb$, by precipitation with acetone from a solution of antimony oxide in excess of tartaric acid. The compounds, $C_4H_7O_5Sb$, previously described by Guntz, and prepared, by using alcohol as a precipitant, are probably mixtures of antimony tartrate and its ester.

Acetylsalicylic acid. U.S. Customs Decision, Jan. 10, 1906.

Acetylsalicylic acid is dutiable at 25 per cent. *ad valorem*, as a "medicinal preparation not containing alcohol, nor made with the use of alcohol," under paragraph 68 of the tariff. The claim of the importer for assessment of duty at 10 c. per lb., under paragraph 1, as "salicylic acid," was overruled. [T.R.] R. W. M.

English Patents.

Camphor [from Isoborneol]; Manufacture of ——. O. Imray, London. From Soc. Chem. Industry, Basle, Switzerland. Eng. Pat. 2520, Feb. 1, 1906.

The process claimed for the manufacture of camphor, is by treating isoborneol suspended in water with a hypochlorite, in the presence or absence of a small proportion of an oxygen carrier. (See Fr. Pat. 352,888 of 1905; this J., 1905, 985.)—F. Shdn.

Ortho-toluene sulpho-chloride. O. Oberländer, Manchester, and the Alliance Chemical Co. Ltd., Bury, Lancs. Eng. Pat. 2304, Feb. 6, 1905.

Ortho-toluene-sulphonic acid crystals obtained by the precipitation of their solution in sulphuric acid with water as described in Eng. Pat. 14,390 of 1901 (this J., 1902, 1024) are treated with chlorosulphonic acid at the ordinary temperature. After standing for several hours, the mixture is poured into ice water and ortho-toluene-sulphochloride is thereby obtained. (Reference is made to Eng. Pats. 11,676 of 1900, and 6537 of 1901; this J., 1901, 504 and 746.)—F. Shdn.

Benzoyl-salicylic acid. J. Wetter, London. From F. Hoffmann-la Roche and Co., Bâle, Switzerland. Eng. Pat. 10,093, May 13, 1905.

True benzoyl-salicylic acid, $C_6H_4(O.CO.C_6H_5)COOH$, is produced when disodium salicylate is allowed to act on benzoyl chloride diluted with ether or light petroleum, provided the benzoyl chloride is employed in molecular quantity or slight excess, and high temperatures are avoided. Benzoyl-salicylic acid is sparingly soluble in water, easily in ether, alcohol and chloroform, and after recrystallising from alcohol melts at 132° C. On boiling with alkalis, it splits up into benzoic and salicylic acids.
—F. Shdn.

Para-aminobenzoic ether [ester]; Manufacture of new salts of ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 12,292, June 13, 1905.

See Fr. Pat. 355,193 of 1905; this J., 1905, 1189.—T. F. B.

Aminoalcohols; Manufacture of new esters of ——, *of salts thereof and of new intermediate products for use therein.* H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 12,843, June 21, 1905.

See Fr. Pat. 355,367 of 1905; this J., 1905, 1189.—T. F. B.

Guaiacol sulphonic acids and salts thereof. R. E. Ellis, London. From Chem. Fabr. von Heyden, Akt.-Ges., Radebeul, Germany. Eng. Pat. 16,723, Aug. 7, 1905.

The mixture left after sulphonating guaiacol is treated with excess of chalk in the usual way. To the clear filtrate half a molecule of lime, or other alkaline-earth or oxide of a heavy metal, is then added. This precipitates the para acid as an insoluble basic salt, leaving the ortho acid in solution. Pure para-guaiacol sulphonic acid gives a precipitate with an ammoniacal calcium or barium chloride solution. The potassium salt, when treated with concentrated nitric acid, gives a yellow precipitate of dinitro-guaiacol. Pure ortho-guaiacol sulphonic acid gives no precipitate when treated with the same reagents.
—F. Shdn.

Therapeutical compound [Glycol monosalicylic ester]; Manufacture of a ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 80, Jan. 1, 1906.

The monosalicylic ester of glycol is prepared by heating together salicylic acid (75 parts) and an ethylene halohydrin (*e.g.*, ethylene chlorhydrin, 45 parts) for a few hours at 140°—150° C. The product is poured into water, made alkaline with sodium carbonate, extracted with ether and the ethereal extract distilled *in vacuo*. The resulting pure ester boils at 169°—170° C. (12 mm.) and melts at 37° C. It is stated to be of value in therapeutics as a substitute for salicylic acid.—T. F. B.

United States Patent.

Alcohols; Process of producing aromatic ——. C. Mettler, Munich, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 815,193, March 13, 1906.

See Eng. Pat. 18,674 of 1905; this J., 1905, 1188.—T. F. B.

French Patents.

Menthylsalicylic ether; Process of making ——. R. Scheuble and B. Bibus. Fr. Pat. 358,948, Oct. 28, 1905.

See Eng. Pat. 8544 of 1905; this J., 1906, 233.—T. F. B.

Cholic acid; Process of making mercury salts of ——. J. D. Riedel, Akt.-Ges. Fr. Pat. 359,069, Nov. 2, 1905.

See Eng. Pat. 11,180 of 1905; this J., 1905, 939.—T. F. B

Antimony lactate; Manufacture of double salts of ——. Chem. Fabr. von Heyden, Akt.-Ges. Fr. Pat. 359,084, Nov. 3, 1905.

See Eng. Pat. 21,751 of 1905; this J., 1906, 134.—T. F. B.

Hydrogen peroxide; Electrolytic preparation of ——. Consortium für Elektrochem. Ind. G.m.b.H. Fr. Pat. 358,806, Oct. 24, 1905. XII., page 321.

Phosphorescent substances in the form of powder or stone; Process for the manufacture of ——. L. Vanino and R. Lambrecht. Fr. Pat. 359,038, Oct. 31, 1905.

It is known that the phosphorescence of alkaline-earth sulphides is considerably increased by the addition of very small quantities of bismuth salts. The patentees find that a still greater effect is produced by the addition of small quantities of thorium or thallium, or, especially lithium salts. In order to obtain the phosphorescent material in the form of stone, it is introduced into a fused substance. For example, potassium nitrate is fused and the powdered phosphorescent substance is introduced. On cooling, the mass sets hard.—A. S.

German Patents.

Eucalyptol-formaldehyde compound; Process of preparing a ——. F. Henschke. Ger. Pat. 164,884, Nov. 20, 1904.

Condensation products may be obtained from eucalyptol and formaldehyde by their interaction in presence of a condensing agent, such as an alkali hydroxide or an acid. The resulting compound is very easily resolved into its components.—T. F. B.

Hexamethylenetetramine; Process of preparing ammonium compounds of ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 164,510, May 14, 1904.

"Ammonium compounds" are obtained by the action of hexamethylenetetramine on halogenalkylimides of aromatic acids, either in benzene or chloroform solution, or by heating the components together *in vacuo*: from bromethylphthalimide, a compound of the constitution, $C_6H_4(CO)_2{:}N.C_2H_4.N(Br)$: $C_6H_{12}N_2$, is obtained. —T. F. B.

C-C-Dialkylbarbituric acids; Process of preparing ——. E. Merck. Ger. Pat. 165,225, July 20, 1904. Addition to Ger. Pat. 162,280, Jan. 9, 1904.

Cyanodialkylacetylureas are converted directly into *C-C*-dialkylbarbituric acids by heating with concentrated mineral acids for a longer time than is necessary for their conversion into dialkylmalonuric amides, internal condensation of the latter taking place.—T. F. B.

C-C-Dialkylbarbituric acids; Process of preparing ——. A. Einhorn. Ger. Pat. 165,649, Nov. 24, 1904.

Dialkylthiobarbituric acids are converted into dialkylbarbituric acids by heating with a mineral acid which has no oxidising action (*e.g.*, phosphoric acid, hydrochloric acid, sulphurous acid). The reaction may be accelerated by the addition of alcohol. (Compare Eng. Pat. 22,967 of 1903; this J., 1904, 76.)—T. F. B.

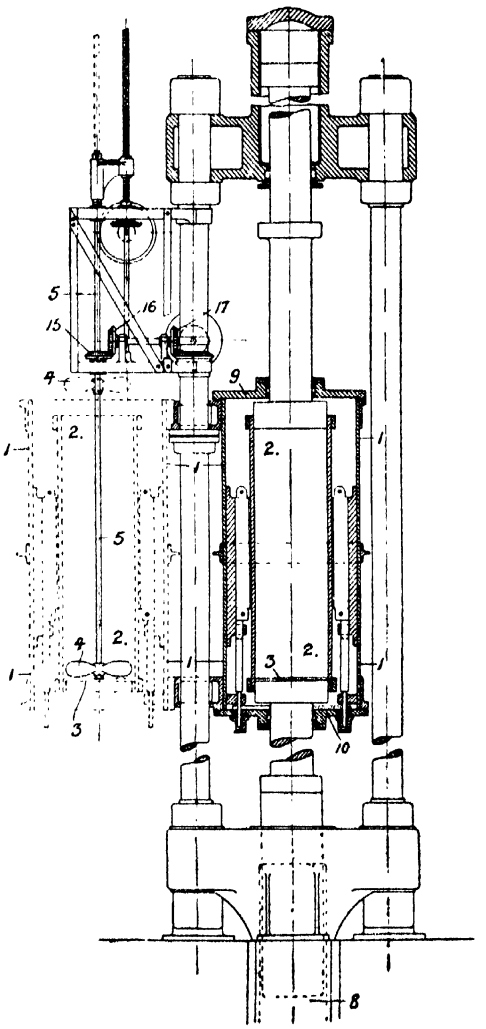
XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 284.)

United States Patent.

Photography; Trichromatic ——. B. Jumeaux and W. N. L. Davidson, Brighton. U.S. Pat. 814,215, March 6, 1906.

See Eng. Pat. 3780 of 1903; this J., 1904, 337.—T. F. B.



XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page* 285.)

English Patents.

Guncotton blocks; Manufacture of pressed or solidified ——, *from the loose or open state.* A. Musker, Bootle, Lancs. Eng. Pat. 3725, Feb. 23, 1905.

The invention consists in the use of an apparatus for mixing guncotton with water which is attached to a hydraulic press, so that the vessel containing the guncotton can readily be swung into position for compressing the pulp into blocks. In the attached drawings the container, 2, held by means of a cylinder, 1, attached to one of the columns of the press, is shown to the left, in dotted lines. At the bottom of the container is a plate, 3, on which the charge rests. Before charging, the blades, 4, of the revolving stirrer, 5, are arranged in position at the bottom of the container, and as the charge is introduced, it is thoroughly stirred, the stirrer being gradually raised by means of the gear fixed above (16 and 17) until the blades are in the position shown by the dotted lines, 4. The container, and cylinder are then swung into position

between the rams of the press, the covers, 9, and 10, are slipped on and bolted tight, and the contents are compressed. The expressed water flows away through perforations in the container, 2, which extend between the edges of the jacket, a layer of filter paper being introduced to prevent the loss of solid guncotton. When the guncotton has been sufficiently compressed, the cylinder can be swung back into its former position, the container removed, and a fresh one substituted for repeating the operation.—B. J. S.

Explosives containing nitroglycerine. J. Wetter, London. From Westfälisch-Anhaltische Sprengstoff A.-G., Berlin. Eng. Pat. 4057, Feb. 27, 1905.

See Fr. Pat. 351,805 of 1905; this J., 1905, 903.—T.F.B.

Explosives. E. Louis, Houilles, France. Eng. Pat. 4372, March 2, 1905. Under Int. Conv., March 2, 1904.

See Fr. Pat. 340,913 of 1904; this J., 1904, 837.—T. F. B.

Smokeless powders; Impts. in ——. A. T. Cocking and Kynoch, Ltd., Birmingham. Eng. Pat. 12,892, June 22, 1905.

FIG. 1.

FIG. 2.

FIG. 3.

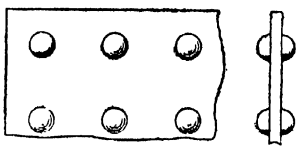


FIG. 4.

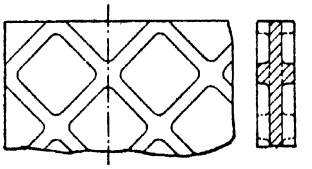

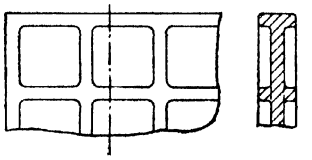

FIG. 5.

Irregularity in rate of burning occurs with all the known forms in which propellants are used. With the cord form the surface exposed, diminishes as the material burns; the flat surfaces of strip or flake powders adhere, whilst tubular powder is apt to split longitudinally; in each case a variation of pressure is produced. The inventors use a modification of the strip or ribbon form with ribs to prevent contact of the flat surfaces. These ribs may be used as shown in section in Figs. 1 and 2, in the form of studs as in Fig. 3, or as a network as in Figs. 4 and 5. The strips may be cut into flakes if desired.

—B. J. S.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUALITATIVE.

Platinum and iridium salts; Action of sulphuric acid on ——, in presence of ammonium sulphate. [Detection of iridium in commercial platinum.] M. Delépine. VII., page 314.

INORGANIC—QUANTITATIVE.

Carbon monoxide; Difficulties in the determination of —— in gaseous mixtures. A. Gautier and Clausmann. Comptes rend., 1906, **142**, 485—491.

In determining carbon monoxide, when present to the extent of several cubic centimetres in gaseous mixtures, the author finds that after the gas has been washed with potassium hydroxide, bromine water and pyrogallol, the cuprous chloride solution, even when present in considerable excess, does not absorb all the carbon monoxide present. Further, carbon monoxide diluted with an inert gas is not burnt completely, even when exploded in presence of excess of oxygen, owing to its resistance to oxidation in presence of other combustible gases. The author recommends that the residual gases, either after absorption with cuprous chloride or explosion with oxygen, be caused to pass over iodic anhydride heated to 70° C. which oxidises the last traces of carbon monoxide.

—E. F. A.

Nitre; Analysis of ——. R. Bensemann. Z. angew. Chem., 1906, **19**, 471—473.

The author's process (this J., 1905, 691), needs modification for potassium nitrate, or for sodium nitrate containing notable amounts of the potassium salt. The solution of the salt (100 c.c.) is evaporated to dryness with 16 grms. of oxalic acid, then mixed to a thin paste with water and a further 8 grms. of oxalic acid, evaporated to dryness again, mixed again with water and 8 grms. more of oxalic acid and evaporated a third time. It is now wetted with water and evaporated five times, brought into a platinum dish, which is covered and placed in a porcelain basin 22 cm. in diameter and 6 cm. high, where it is cautiously heated till acid fumes are no longer evolved. It is then gradually heated over a powerful burner to bright redness till perfectly white, which requires about an hour. The cooled substance is then treated exactly as sodium nitrate.

Instead of this method, the following is often more convenient: (*a*) The chloride is determined in 50 c.c. of the solution. (*b*) 50 c.c. diluted to 500 c.c. are evaporated to dryness with 50 c.c. of concentrated hydrochloric acid; this is repeated five times, then the mass is five times wetted with water and evaporated to dryness, and the chloride in the residue determined. This gives chloride equivalent to chloride + chlorate + nitrate in the original substance. (*c*) The salt is ignited, and the chloride in the residue determined, which is equivalent to chloride + chlorate + perchlorate in the original. (*d*) The salt after ignition is treated as in (*b*) which gives chloride equivalent to chloride + chlorate + perchlorate + nitrate. The mode of calculating from these four results, the amounts of each of the four separate salts is obvious.

This latter "chloride method" is much less laborious than the first, or "carbonate method," but always gives higher nitrate figures. The author has not yet discovered the reason of this, nor which figure is nearer the truth.

—J. T. D.

Iron; Determination of —— by bichromate, using diphenylcarbohydrazide [diphenylcarbazide] as indicator. L. Brandt. Z. anal. Chem., 1906, **45**, 95—99.

In the determination of iron by titration with bichromate solution, diphenylcarbohydrazide (see this J., 1900, 1007, 1040) has the advantage over other indicators of being used in the titrating vessel, and not outside it. The method is as follows:—To about 1½ litres of water in a capacious dish are added 60—80 c.c. of dilute hydrochloric acid (sp. gr. 1·12) and 100 c.c. of a solution containing 10 grms. of manganese sulphate, 55 c.c. of dilute sulphuric acid, 1:3, and 5 c.c. of phosphoric acid of sp. gr. 1·7. The iron solution, which should contain 0·2—0·5 grm. of iron, and 5 c.c. of a 0·1 per cent. solution of the indicator are further added, and the titration with bichromate performed. There is, at first, a bright red-violet colour which finally changes sharply to the green of chromic chloride.

The indicator may also be employed in the determination of chromic acid, an excess of standard ferrous ammonium

sulphate solution being added, and the process completed as above described.

The solution of the indicator in acetic acid should be prepared fresh every few days.—F. SODN.

Ferric chloride; Reduction of —— by zinc. D. L. Randall Z. anorg. Chem., 1906, **48**, 389—392.

AMALGAMATED zinc has generally been considered applicable only to the reduction of sulphuric acid solutions of iron for its determination by permanganate. It is found, however, that it can be applied equally well to ferric chloride, provided that the titration is carried out in presence of manganous sulphate and with sufficiently dilute solutions. Under these conditions, excess of hydrochloric acid is no disadvantage; thus 25 c.c. of the acid may be present if the solution of about 0·5 grm. of iron be diluted to 1 litre.—T. F. B.

Silver and gold; Determination of ——. C. Goldschmidt. Z. anal. Chem. 1906, **45**, 87.

METALLIC silver is precipitated as a black powder from solutions containing it when boiled with sheet cobalt. In like manner sheet nickel, dipped into boiling solutions of gold salts, precipitates the metal as a brown powder. The reactions may be used quantitatively, the precipitates being weighed.—F. SODN.

Tungsten and tin; Separation of ——. E. Donath. Z. angew. Chem., 1906, **19**, 473—474.

THE mixed tungstic and stannic oxides are heated in a covered porcelain crucible with zinc dust or zinc filings, for a quarter of an hour, and after cooling, the mass is heated with 1:2 hydrochloric acid till no more hydrogen is evolved, and all the metallic tin is, therefore, dissolved. To the cooled liquid, potassium chlorate is cautiously added till the blue colour has entirely disappeared, and the tungsten is entirely in the form of dioxide. The liquid is now diluted with at least one and a half times its volume of water, and allowed to stand for 24 hours, when the whole of the tungstic oxide is deposited. It is filtered off, washed first with water containing nitric acid, and finally with a hot dilute solution of ammonium nitrate, dried, ignited, and weighed. In the filtrate the tin is precipitated as sulphide.—J. T. D.

Cement testing. O. H. Klein and S. F. Peckham. Report on Portland cements. J. C. Hertle and W. H. Black. July 27, 1905.

THIS report on cement testing was prepared for the Commissioners of Accounts of the City of New York, and is a discussion on "the determination of a method for a comparative analytical examination of cements, cement mortars and concretes, corelative with their properties as revealed by physical tests."

The method includes the following determinations (1) matter volatile at a red heat; (2) matter insoluble in 10 per cent. hydrochloric acid; (3) soluble silica; (4) alumina and ferric oxide; (5) lime; (6) magnesia; (7) sulphuric acid. For the analysis of 5 grms. of cement, or 10 grms. of mortar are taken. The filtrate and washings from the silica are made up to 1 litre, and the iron and alumina determined in 100 c.c. of this by double precipitation with ammonium hydroxide. The lime is precipitated in the filtrate from the iron and alumina by ammonium oxalate, and ignited with the aid of the blowpipe for 15 minutes. The filtrate from the lime is rendered acid with hydrochloric acid, evaporated to about 150 c.c. and 30 c.c. of a saturated solution of microcosmic salt added. The solution is boiled and cooled, and then ammonia is added with constant stirring, avoiding more than a slight excess until the precipitate begins to form. The sulphuric acid is determined as barium sulphate in 100 c.c. of the solution left in the litre flask.—W. C. H.

Mercury ores; Assay of ——. G. T. Holloway. Analyst, 1906, **31**, 66—71.

THE author describes a modified apparatus for carrying out Eschka's method of determining small quantities of mercury (Z. anal. Chem., **2**, 334). In this method the ore is heated with iron filings in a crucible covered with a weighed gold disc hollowed out into the form of a cup, in which water is placed; the mercury condenses on the gold and is weighed. R. E. Chism (this J., 1898, 1183) replaced the gold cup by silver foil, but the author states that difficulty is experienced in fitting either the gold cup or silver foil "mercury-tight" to the crucible. He proposes a cover consisting of a flat disc of "fine" silver, free from pin-holes, on which is placed a copper box provided with inlet and outlet tubes for a current of cold water.—A. S.

ORGANIC—QUALITATIVE.

Cotton and linen; Test to differentiate ——. A. Herzog. Rev. Intern. Falsific., through Apoth.-Zeit., 1905, **20**, 891.

A SMALL piece of the material is macerated in a tepid alcoholic solution of Cyanine, washed free from excess of the dyestuff with water, then immersed in dilute sulphuric acid. Cotton is completely decolorised by this treatment, but the linen fibres retain the blue tint. If the material be then washed with water, and immersed in solution of ammonia, the colour of the flax fibres is intensified.—J. O. B.

Levulose; Detection of ——, in the presence of dextrose and dextrosamine. C. Neuberg. Z. physiol. Chem., 1905, **45**, 500; J. Pharm. Chim., 1906, **23**, 302—303.

LEVULOSE, when heated with *a*-methylphenylhydrazine acetate, gives an osazone, whilst dextrose, similarly treated, yields the corresponding hydrazone. The osazone is readily detected by its colour and is separated from the hydrazone by means of the usual solvents. The mixture of sugars and *a*-methylphenylhydrazine acetate should be heated on the water-bath for five minutes, and then allowed to cool to the ordinary temperature. Dextrosamine hydrochloride yields no trace of osazone when treated with *a*-methylphenylhydrazine acetate, and may also be distinguished from levulose by means of phenyl isocyanate (Stendal's method), or by oxidation into isosaccharic acid.—W. P. S.

Cocoa-nut fat in butter; Process for the detection of ——. H. P. Wijsman and J. J. Reijst. XII., page 324.

Cocoa and chocolate; Detection of foreign substances in ——. F. Bordas and Touplain. Comptes rend., 1906, **142**, 639—641.

THE cocoa, from which fat and matters soluble in water have been removed, is treated by flotation in a series of liquids (mixtures of carbon tetrachloride and benzene) of densities 1·440, 1·500, 1·530, 1·600. The flotation separations are rendered quicker and more certain by the use of a centrifugal machine, and thus earthnut husks and cocoa seeds, pure cocoa, cocoa husks, potato starch, and mineral matter are successively separated. The method is applicable to other powdered aliments.—J. T. D.

UNITED STATES PATENT.

Distilled liquids; Process for ascertaining the origin of colouring matters present in ——. C. T. Marsh, Assignor to L. H. Weissleder, Cincinnati, Ohio. U.S. Pat. 813,728, Feb. 27, 1906.

FOR testing the nature of the colouring matter of whiskey, amyl alcohol is distilled in presence of a caustic alkali and the clear distillate is mixed with water and with the whiskey to be tested. When the mixture is allowed to stand at rest, it separates into an upper alcoholic layer and a lower aqueous layer. If the whiskey contain artificial colouring matters, the aqueous layer is coloured by them, whilst, if the colouring matters be such as are acquired by the process of ageing, the aqueous layer remains clear.—J. F. B.

ORGANIC—QUANTITATIVE.

Fats; A reagent in the chemistry of ——. [*Naphthalene-stearosulphonic acid.*] E. Twitchell. XII., page 324.

Lactic acid [Commercial]; Analysis of ——. M. Philip. Collegium, 1906, 88—90.

THE presence of anhydride in commercial lactic acid renders the determination of the latter by direct titration untrustworthy. The following method is, therefore, proposed:—About 5 grms. or 5 c.c. of the sample are diluted with water and titrated with N/1 sodium hydroxide solution, using phenolphthalein as indicator. A measured excess of the alkali solution is then added, the mixture boiled, and the excess of alkali titrated back. The first titration gives the amount of actual lactic acid, and the quantity of alkali used in the second corresponds with the amount of anhydride present. One c.c. of N/1 alkali corresponds to 0·09 grm. of lactic acid and with 0·162 grm. of the anhydride. Sulphuric acid should always be tested for in the sample, and, if present, must be determined and allowed for in the foregoing titrations.
—W. P. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Jewels; Coloration of —— by radium rays. A. Miethe. Ann. der Physik, No. 3, 1906; Electrician, 1906, **56**, 887.

ON exposure to a "preparation of 60 mgrms. of radium bromide," a colourless diamond from Borneo, was coloured a light yellow after eight days, and a decided lemon-yellow after a further eight days. On heating to 250° C. the yellow coloration was diminished, but the colour was not entirely destroyed even on heating to redness. A colourless Brazil diamond was not coloured by exposure to the radium rays. On exposing a light blue sapphire from Ceylon to radium rays, after two hours the colour changed to green, then to light yellow, and, after a few more hours, to reddish-yellow; after a fortnight the colour was dark yellow or nearly chestnut. The colour disappeared on heating the sapphire, but the light yellow tint was always regained on cooling. Ruby, amethyst, blue topaz and chrysoberyl were not affected by radium rays. Tinted tourmaline was not changed to any considerable extent, but a stone having a pink colour at one end acquired a red colour, and a tourmaline having a green end acquired a green colour at any section by exposure to radium rays.—A. S.

Trade Report.

ARGENTINA; TRADE OF —— IN 1905.
Bd. of Trade J., March 15, 1906.

The following table shows the value of certain articles imported during the years 1904 and 1905:—

Articles imported.	1904.	1905.
	$	$
Textiles	56,819,229	46,218,951
Stoneware, glass and ceramic goods	15,905,293	17,466,903
Wines, spirits, &c	7,790,815	9,167,842
Chemicals and pharmaceutical products	6,014,344	6,275,786
Oils	6,205,756	5,556,067
Paper and manufactures of paper	4,023,720	4,133,842
Leather and manufactures of leather	1,410,017	1,796,844
Colours and dyes	1,154,439	1,441,726

The values of certain exports from Argentina during the past two years were as follows:—

Exports.	1904.	1905.
	$	$
Wool in the grease	48,355,002	64,312,927
Hides and skins	24,539,712	30,509,533
Linseed	28,359,923	26,233,851
Quebracho extract	2,011,130	2,427,772

NOTE.—The dollar referred to is the gold dollar, worth about 4s.

New Books.

ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES FOR 1904. Part II. Statistics. Wyman and Sons, Fetter Lane, E.C. [Cd. 2484.] Price 7d.

THIS second part of the Annual Report of the Work of the Factory Department contains statistics as to the staffs of the various factories, surgeons' reports, poisoning cases, accidents, and prosecutions, together with a classification of the non-textile industries. Returns of employment are also given in detail.

GAS UNDERTAKINGS. Return relating to all authorised Gas Undertakings in the United Kingdom other than those of Local Authorities, for the year ended Dec. 31, 1904 (in continuation of Parliamentary Paper, No. 331 of 1904). 320. Price 10d.

GAS UNDERTAKINGS (LOCAL AUTHORITIES). Returns relating to all authorised Gas Undertakings in the United Kingdom belonging to Local Authorities, for the year ended March 25, 1905 (in continuation of Parliamentary Paper No. 332 of 1904). 321. Price 5½d.

ACCORDING to these Returns, which have been prepared in the Board of Trade by order of the House of Commons, there were in 1904, 469 authorised gas undertakings in the United Kingdom, other than those belonging to local authorities, as compared with 459 in 1903. The number of such undertakings belonging to local authorities in the year 1904-5 was 265, as compared with 260 in the year 1903-4.

NEW CUSTOMS TARIFF OF RUSSIA AS MODIFIED BY COMMERCIAL TREATIES WITH GERMANY AND FRANCE. Wyman and Sons, Fetter Lane, E.C. [Cd. 2857.] Price 9d.

THE present tariff came into force on March 1, 1906. The following are among the classes dealt with under "Import duties" (the numbers referring to those in the tariff):—40—56, Animal products; 65—72, Building materials, stone, &c; 73—76, Earthenware and porcelain; 77—8, Glass; 79, Coal; 80—87, Tar, pitch, gums and resins; 88, India-rubber and manufactures thereof; 89—123, Chemical and pharmaceutical products; 124—137, Dyeing and tanning materials and colours; 138—166, Metals and manufactures thereof; 176—178, Paper and wares thereof; The return also contains a list of substances of which importation is prohibited, and a tariff of export duties.

BULGARIA: NEW CUSTOMS TARIFF OF ——. [Cd. 2862.] Price 6d. Messrs. Wyman and Sons, Ltd., Fetter Lane, E.C.

THIS translation of the Bulgarian customs tariff has just been published by the Board of Trade, and includes the modifications made by the conventions concluded with the United Kingdom, France, Germany and Italy. The tariff came into force on Jan. 14th last.

ANNUAL STATEMENT OF THE TRADE OF THE UNITED KINGDOM, 1904. Supplement to Volumes I. and II. [Cd. 2668.] Price 5s. 10d.

THIS return contains abstract and detailed tables showing the countries of consignment of imports and countries of ultimate destination of exports. In Volumes I. and II. of the "Annual Statement of Trade" imports are generally classified as received from the countries whence they were shipped direct to the United Kingdom, and exports to countries possessing no seaboard are credited to the country in which the port of discharge is situated. The present volume also contains statements of the consignments from each country retained for consumption in the United Kingdom, or the "special" imports from each country into the United Kingdom.

A Treatise on Producer-Gas and Gas-Producers. By Samuel S. Wyer, M.E., Member of the American Institute of Mining Engineers. Engineering and Mining Journal. 505, Pearl Street, New York, 1906. Price, 4 dols., post paid. 20, Bucklersbury, London.

8vo. volume, containing 276 pages of subject matter, with 113 illustrations, followed by a bibliography of works, &c., on Gas-Producers, filling 14 pages, and the alphabetical index. The text is sub-divided as follows:—I. Fundamental Physical Laws and Definitions. II. Fundamental Chemical Laws and Definitions. III. Thermal and Physical Calculations. IV. Commercial Gases. V. Status of Producer-Gas. VI. Classification of Gas-Producers. VII. Manufacture and Use of Producer-Gas. VIII. Use of Steam in Gas-Producers. IX. Carbon Dioxide in Producer-Gas. X. Efficiency of Gas-Producers. XI. Heat Balance of the Gas-Producer. XII. Fuel. XIII. Requirements. XIV. History of Gas-Producers. XV. American Pressure Producers. XVI. American Suction Gas-Producers. XVII. Gas-Cleaning. XVIII. By-Product Gas-Producers. XIX. By-Product Coke Oven Gas-Producers. XX. Producer-Gas for Firing Ceramic Kilns. XXI. For Firing Steam Boilers. XXII. Wood Gas-Producers. XXIII. Removal of Tar from Gas. XXIV. Gas-Producer Power Plants. XXV. Operation of Gas-Producers XXVI. Testing Gas-Producers. XXVII. Future of the Gas-Producer. XXVIII. Gas Poisoning.

Jahrbuch der Oesterreichischen Chemischen Industrie (Chemische Industrie, Gummi, Gaswerke, Petroleum, Kerzen und Seifen). Herausgegeben von Rudolf Hanel. Jahrgang 1906. Alfred Hölder, K.U.K. Hof. und Universitäts-Buchhändler, Wien, 1906. Price K.3.80. "Compassverlag," Maria Theresienstr. 32. Vienna. I.

This volume, of small 8vo size, is a directory of the Austrian Chemical Industrial firms, and the contents fill 300 pages, and besides the mere addresses of firms and proprietors, it gives also dates as to year of foundation, number of workpeople; horse-power; kind of motive power; telegraphic addresses; various statistics; prices, &c.

Das neue Technisch-Chemische Institut der Königlichen Technischen Hochschule zu Berlin und die Feier seiner Eröffnung am 25, November, 1905. Von dem Direktor des Instituts, Dr. Otto N. Witt, Geheimer Regierungsrat und Profesor. Weidmannsche Buchhandlung, 94 Zimmerstr. Berlin S.W. 12. 1906. Price, M.12.

This large 8vo pamphlet contains a full report of the Royal Technical High School of Berlin, of which Professor Otto N. Witt is the Director. The Report fills 16 pages and is beautifully illustrated both in the text, and by means of photo-lithographic plates. As an illustration of the work done in the Electro-Chemical Laboratory, the working out of Frank's electro-chemical method of utilising the nitrogen of the air is cited (Prof. Frank having carried out a portion of his investigations here), his investigations, with those of others, leading up to the system and method now adopted at Notodden, in Norway, of which the localities, works, and apparatus are fully illustrated. The Report as a whole is a reprint in separate form of the article appearing in the *Chemische Industrie*, 1905, 28, 699—707. (This J., 1906, 27.)

Chemie der Organischen Farbstoffe. von Dr. Rudolf Nietzki, o. Professor an der Universität zu Basel. 5ᵉumgearbeitete Auflage. Julius Springer's Verlag. Monbijouplatz 3. Berlin. Price, M.8.

8vo. volume, containing 355 pages of subject matter, and the alphabetical index. The text is sub-divided as follows:—Introduction: Causes of Colouring Power. Chromphors: Chromogens; the dyeing process. Dyeing on Mordants. Constitution of Chromogens, &c. I. Nitro Compounds. II. Azo-dyestuffs. III. Hydrazone-, Pyrazolone-dyestuffs and Formazyls. IV. Azomethins and Stilbene dyestuffs. V. Hydroxyquinones and Quinone-oximes, (Anthracene dyestuffs). VI. Diphenyl- and Triphenylmethane Dyestuffs. VII. Imido-quinone Dyestuffs. VIII. Aniline Black. IX. Quinoline- and Acridine Dyestuffs. X. Thiazol- and Sulphide Dyestuffs. XI. Hydroxyketone Dyestuffs: Xanthone, Flavone; Cumarin and Indone. XII. Dyestuffs of the Indigo Group. XIII. Appendix with Orseille, Litmus, Canarin and Murexide.

Methods of Organic Analysis. By Henry C. Sherman, Ph.D., Adj. Professor of Analytical Chemistry in Columbia University. The Macmillan Company, New York. Macmillan and Co., Ltd., London, 1905. Price, 7s. 6d.

Large 8vo. volume, containing 237 pages of subject matter, and an alphabetical Index. The subject matter is classified as follows:- I. Introduction: Organic Analysis, &c. II. Nitrogen, Sulphur, and Phosphorus. III. Alcohols and Glycerol. IV. Aldehydes. V., VI., and VII. Carbohydrates. General Methods and Special Methods. VIII. Acids. IX. Oils, Fats, and Waxes. General Methods. X. Fatty Oils, Special Methods. XI. Butter. XII. Soaps and Lubricants. XIII. Proteids and Cereals. XIV. Milk.

The Polariscope in the Chemical Laboratory. An Introduction to Polarimetry and Related Methods. By George Wm. Rolfe, A.M., Instructor in Sugar Analysis in the Massachusetts Institute of Technology. The Macmillan Company, New York. Macmillan and Co., Ltd., London, 1905. Price, 8s. net.

Small 8vo. volume, containing 277 pages of subject matter, with 38 illustrations, five pages of Bibliography, 30 pages of tables, and an Alphabetical Index.

The subject matter is sub-divided and classified as follows:—I. Fundamental Principles. II. The Polariscope. III. The Saccharimeter. IV. Accuracy of Saccharimeter Measurements. V. Apparatus and Laboratory Manipulation. VI. Special Instruments. VII. Polarisation of Cane Sugar and General Commercial Methods. VIII. Determination of Sucrose in Presence of other Optically Active Substances. IX. Sugarhouse and Refinery Methods. X. Chemical Methods of Determining Sugars. XI. Starch and Starch Products. XII. Miscellaneous Saccharine Products. XIII. Polariscope in Scientific Research. XIV. Use of Polariscope in Chemical Analysis. XV. Other than Carbohydrate Determinations.

Society of Chemical Industry

No. 8.—Vol. XXV. SUPPLEMENT. APRIL 30, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Dr. Edward Divers, F.R.S.
GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

OFFICES:—
Telegraphic Address: "59 *Palatable, London.*" 59, Palace Chambers, Westminster, S.W. *Telephone No.:* "913, Victoria."

Journal and Patent Literature.

Class.		Page.
I.	General Plant, Apparatus and Machinery	362
II.	Fuel, Gas, and Light	363
III.	Destructive Distillation, Tar Products, Petroleum, and Mineral Waxes	365
IV.	Colouring Matters and Dyestuffs	367
V.	Preparing, Bleaching, Dyeing, Printing and Finishing Textiles, Yarns, and Fibres	370
VI.	Colouring Wood, Paper, Leather, &c.	373
VII.	Acids, Alkalis, and Salts, and Non-Metallic Elements	373
VIII.	Glass, Pottery, and Enamels	374
IX.	Building Materials, Clays, Mortars, and Cements	375
X.	Metallurgy	376
XI.	Electro-Chemistry and Electro-Metallurgy	379
XII.	Fatty Oils, Fats, Waxes, and Soap	381
XIII.	Pigments and Paints; Resins, Varnishes, &c.; India-Rubber, &c.	[illegible]

XXII.	Explosives, Matches, &c.	[illegible]
XXIII.	Analytical Chemistry	[illegible]
XXIV.	Scientific and Technical Notes	[illegible]

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—6*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications received, the Treasurer is requested to receive [illegible]

List of Members Elected.

April 23rd, 1906.

Alder, H. W., 18, Holyhead Road, Coventry, Warwickshire, Chemist.

Bell, H. W., Tay Street, Invercargill, New Zealand, Company Manager.

Brown, Percy S., c/o Western Electric Co., West and Bethune Streets, New York City, U.S.A., Chemist.

Campbell, Geo. H., 15, Spadina Road, Toronto, Canada, Manufacturing Chemist.

Christie, Dr. W. A. K., 5, Penywern Road, Clydach, R.S.O., Glamorgan, Technical Chemist.

Dains, F. B., Washburn College, Topeka, Kansas, U.S.A., Professor of Chemistry.

Dean, Harry, Armstrong College, Newcastle-on-Tyne, Demonstrator.

Doty, Henry D., c/o Manhattan Rubber Manufacturing Co., Passaic, N.J., U.S.A., Chemist.

Egleson, J. E., Capelton, Quebec, Canada, Chemist.

Fiske, Augustus H., 141, Milk Street, Boston, Mass., U.S.A., Chemist.

Frank, Emil, 41, North 40th Street, Philadelphia, U.S.A., Publisher.

Gibson, Robert R., c/o [illegible] Co., Roebling, N.J., U.S.A., Chemist.

[illegible]

Gater, Walter T., c/o Evans, Sons, Lescher and Webb, Ltd., 60, Bartholomew Close, E.C., Chemist.

Gray, Rt. Albert, Rose Mount, Higherfield, Halifax, Chemist.

Hibbelar, Conrad, c/o Swift and Co., Soap Works, Somerville, Mass., U.S.A., Superintendent.

Hutchings, W. Maynard, Easedale, Elmfield Road, Gosforth, Newcastle-on-Tyne, Metallurgist.

Iddings, Richard P., 18, Wyman Street, Lawrence, Mass., U.S.A., Chemist.

Innes, Dr. W. Ross, 6, Griffiths Road, Wimbledon, S.W., Chemist.

Keily, C. L., c/o Ilford, Ltd., Ilford, E., Chemist.

Kerr, Chas. H., 7022, Paschall Avenue, Philadelphia, Pa., U.S.A., Works Chemist.

Liversedge, S. G., Public Health Laboratory, Castle Street, Dublin, Ireland, Analytical Chemist.

Moller, Emil A., 44, Sherman Avenue, Tompkinsville, N.Y., U.S.A., Manager, The Sanitas Co.

Newkirk, Chas. C., c/o The M. Werk Co., 411, Poplar Street, Cincinnati, Ohio, U.S.A., Chemist.

Pring, J. N., Linden Bank, Sandbach, Cheshire, Student.

Purves, George, Y.M.C.A., Dominion Square, Montreal, Canada, Chemist and Works Manager, Standard Chemical Co., Ltd.

Ryan, Irenaeus F., 452, Fairmount Avenue, Jersey City, N.J., U.S.A., Chemist.

Schulten, Dr. C., 11, Clive Row, Calcutta, India, Analytical Chemist.

Setz, C. F., Herculaneum, Mo., U.S.A., Chemist and Metallurgist.

Shaw, H. G., Box 373, Barberton, Ohio, U.S.A., Chemist.

Silverman, Max, Park Hotel, Williamsport, Pa., U.S.A., Chemist.

Solomon, Maurice, c/o General Electric Co., Carbon Works, Witton, Birmingham, Manager, Carbon Works.

Spiers, V. G., Middlepark, Kamptee, Central Provinces, India, Chemist.

Springer, Alfred, 312, East 2nd Street, Cincinnati, Ohio, U.S.A., Chemist.

Sweet, Everell F., 33, Broad Street, Boston, Mass., U.S.A., Importer.

Wallbridge, Wm. K., 16, East 45th Street, New York City, U.S.A., Technical Chemist.

Whiteley, C. E., 21, Brudenell View, Leeds, Demonstrator of Chemistry.

Winkler, S. M., 38 and 40, Main Street, Cincinnati, Ohio, U.S.A., Chemical Merchant.

Withey, Wm. S., c/o Brustad Mines, Ltd., Eidovold, Norway, Assayer and Analytical Chemist.

Yockey, Harry, c/o National Lead Co., 7th and Freeman Streets, Cincinnati, Ohio, U.S.A., Chemist.

Zaremba, Edward, 944, Monadnock Building, Chicago, Ill., U.S.A., Manager, American Foundry and Machinery Co.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the journal depends.

Bowden, Thos., l/o Stubley; Dorn Lea, Todmorden Road, Littleborough, Lancs.

Brannigan, Jas. A., l/o North Star Soap; 603, North 16th Street, Philadelphia, Pa., U.S.A.

Cammack, Jas. R., l/o Rising Sun; 28, Cambridge Street, Worcester, Mass., U.S.A.

Cox, Francis H., Journalist, of the Scarborough Pictorial and Co., Ltd., Dartford, Kent.

Cheesman, Frank P., l/o 92; 100, William Street, New York City, U.S.A.

Clark, T. W. Firth, l/o Highbury Hill; Laboratory, Johnson Street, Mile End, London, E.

Ekenberg, Dr. M., l/o Stockholm; 72, Victoria Street, Westminster, S.W.

Engineers Society of Western Pennsylvania, l/o Penn Avenue; 803, Fulton Building, Pittsburgh, Pa., U.S.A.

Farrell, Frank, l/o Primrose Mansions; 44, Prince of Wales Mansions, Prince of Wales Road, S.W.

Günther, W. G. W., l/o 5; Colonial Sugar Refining Co. Ltd., 1, O'Connell Street, Sydney, N.S.W.

Hamilton, Robt., l/o Tempest Road; 40, Sefton Terrace, Beeston Hill, Leeds.

Haslwanter, Chas., l/o Willoughby Avenue; 86, Pilling Street, Brooklyn, N.Y., U.S.A.

Jessup, A. E., l/o c/o U.S. Consul; all communications to Tientsin, North China.

Kenrick, Dr. F. B., l/o John Street; 73, Baldwin Street, Toronto, Canada.

Kirkland, Robt., l/o Ross Street; 25, Collier Road, Cambridge.

Kohnstamm, L. S.; all communications to 87–89, Park Place, New York City, U.S.A.

Mitsugi, R., l/o Tokyo-fu; retain Journals.

Noake, Frank, l/o Dudley; Parkside Cottage, Dunstall Park, Wolverhampton.

Palmer, Dr. Chas. S.; all communications to 637, Valley Road, Upper Montclair, N.J., U.S.A.

Palmer, T. Chalkley; all communications c/o American Dyewood Co., Chester, Pa., U.S.A.

Powell, A. Ernest, l/o Whalley Range; 46, Monton Street, Moss Side, Manchester, S., Technical Chemist.

Sibley, S. E., l/o Ilford; Tottenham, Warren Road, Marrickville, Sydney, N.S.W.

Tayler, J. B., l/o Liverpool; Anglo-Chinese College, Tientsin, N. China.

Change of Name.

Shimotome, Prof. H., to Soma, Prof. H., Higher Technical School, Asakusa, Tokyo, Japan.

Death.

Griffith, R. W. S., of Eyeworth Lodge, Lyndhurst, Hants. March 29.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 7878. Bottman, Miller and Diller. Apparatus for the mechanical classification of [illegible]. [illegible] 1908. Convention Germany, April 3, [illegible]

[A.] 8165. Rappold. Kilns or furnaces with travelling hearths. April 4.

„ 8278. British Thomson-Houston Co., Ltd. (General Electric Co.). Vessels used in chemical operations. April 5.

„ 8323. Bornett. Apparatus for filtering gases or liquors. April 6.

„ 8374. Harrison. Filter presses. April 7.

„ 8744. Brewis and Allen. Extraction with volatile solvents. April 11.

„ 8812. Hargreaves. Furnaces. April 12.

„ 8911. Pritchard, and The United Alkali Co., Ltd. Apparatus for evaporating solutions. April 12.

„ 8947. James. Method of producing liquid air or other gases. April 14.

[C.S.] 9056 (1905). Burdon (Soc. Anon. des Procédés Maslin-Theryc). Furnaces. April 11.

„ 9264 (1905). Joyce. Kiln for drying hops and the like. April 19.

„ 9441 (1905). Dolhotel. Recovery of volatile solvents. April 19.

„ 9464 (1905). Craig, Craig and Craig. Apparatus for filtering liquids containing fine coal or the like. April 11.

„ 9548 (1905). Kestner. *See under* II.

„ 10,817 (1905). Morison. Apparatus for heating and evaporating liquids by means of steam. April 19.

„ 22,816 (1905). Lorimer. Drying and conditioning machines. April 11.

„ 23,378 (1905). Thwaite. *See under* II.

II.—FUEL, GAS, AND LIGHT.

[A.] 8017. Lee. Manufacture of metallic filaments for incandescent electric lamps. April 3.

„ 8030. Rothberg. Coke ovens. [U.S. Appl., April 8, 1905.]* April 3.

„ 8057 Kuzel. Manufacture of incandescence bodies of difficultly fusible conductive materials with the use of colloidal oxides and hydroxides of difficultly fusible metals. [Ger. Appl., Aug. 3, 1905.]* April 3.

„ 8067. Act.-Ges. f. Selasbeleuchtung. Apparatus for mixing gas and air for illuminating purposes. [Ger Appl., April 4, 1905.]* April 3.

„ 8119. Wright and Westwood. Purifiers of coal-gas plant. April 4.

„ 8154. Terneden and Muller. Manufacture of water gas.* April 4.

„ 8256. Bloxam. (Watergas Maatschappy System Drs. Kramers and Aarts). Manufacture of water gas.* April 5.

„ 8276. Bauke. Suction gas producers.* April 5.

„ 8293. Gardner, Manners, Fairweather and Warnock. Manufacture of gas and apparatus therefor. April 6.

„ 8362. Bellowitsch. *See under* VII.

„ 8433. Jerratsch. Gas retorts.* April 7.

„ 8462. Grove. Petroleum or heavy oil carburettors. April 9.

„ 8486. Gore. Apparatus for enriching and compressing coal gas. April 9.

„ 8521. Allport. Coke oven plant. April 9.

„ 8670. Bauke. Production of gas.* April 10.

„ 8705. Lynde. Production of gas from hydrocarbons. April 11.

„ 8746. Hischemöller. Fuel. April 11.

„ 8752. Taylor, Russell and Haight. Incandescence gas mantles. April 11.

„ 8778. Bauke. Suction gas generators.* April 11.

„ 8782. Burge. Production of acetylene. April 11.

[A.] 8840. Imray (Siemens und Halske A.-G.). Manufacture of incandescence bodies for electric lighting.* April 12.

„ 8866. Page (Doherty). Gas calorimeters.* April 12.

„ 9020. Bloxam (Lux). Manufacture of filaments of tungsten or molybdenum for electric incandescence lamps. April 14.

[C.S.] 7904 (1905). Thwaite. Apparatus for automatically sustaining the suction influence in suction gas producers. April 19.

„ 9548 (1905). Kestner. Removal of dust and other suspended matter from furnace and other gases. April 11.

„ 10,699 (1905). Collin. Coke ovens with regenerator action. April 11.

„ 23,351 (1905). Fraser and Fraser. Burners for liquid fuel. April 19.

„ 23,378 (1905). Thwaite. Separation of dust from gases. April 11.

„ 995 (1906). Gautreau and Gautreau. Vaporisers for combustible liquids. April 19.

„ 1295 (1906). Maschinenfabrik und Mühlenbauanstalt G. Luther, A.-G. Gas producers. April 19.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 7934. Hesse. Purifying pitch oils and other ethereal oils obtained by destructive distillation of resinous substances April 2.

„ 8757. Pagès and Camus. Manufacture of acetone. [Fr. Appl., April 14, 1905.]* April 11.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 8066. Chem. Fabr. vorm. Weiler-ter-Meer. Manufacture of new sulphur dyestuff compounds. [Ger. Appl., Feb. 26, 1906.]* April 3.

„ 8077. Johnson (Badische Anilin und Soda Fabrik). Manufacture of new derivatives of certain polychloranilines.* April 3.

„ 8490. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new mono-azo dyestuffs. April 9.

[C.S.] 7838. (1905). Oehler and Oehler. Production of indophenol sulphonic acids. April 11.

„ 12,756 (1905). Cooper (Bayer und Co.). Manufacture of new anthraquinone dyestuffs April 11.

„ 15,763 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of intermediate compounds and of colouring matters containing sulphur. April 11.

„ 19,186 (1905). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new sulphurised dyestuffs. April 11.

„ 1954 (1906). Johnson (Badische Anilin und Soda Fabrik). Manufacture of Indigo paste. April 11.

„ 4687 (1906). Imray (Soc Chem. Industry in Basle). Manufacture of a red vat dyeing dyestuff. April 11.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 8045. Soc. Franç. de la Viscose. Spinning viscose. [Fr. Appl., April 3, 1905.]* April 3.

„ 8137. Grosvenor and Mackay. Yarn dyeing machines. April 4.

„ 8167. Trocquenet. Non-inflammable material containing cellulose.* April 4.

[A.] 8313. Frankenberg. Manufacture of waterproof materials. [Ger. Appl., Sept. 18, 1905.]* April 6.

„ 8435. Ringenbac. Bleaching textile fabrics.* April 7.

„ 8461. Pickles and Pickles. Finishing fabrics. April 9.

„ 8597. Fuchs. Mordants for cotton and other materials. April 10.

[C.S.] 4746 (1905). Linkmeyer. Manufacture of artificial threads. April 19.

„ 17,241 (1905). Johnson (Badische Anilin und Soda Fabrik). Production of brown shades on the fibre, with or without white or coloured discharge effects. April 19.

„ 4073 (1906). Meister, Lucius und Brüning. Manufacture of ketone sulphoxylates. April 11.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

[A.] 8230. Dick. Process for colouring or staining ivory, bone, horn, celluloid, and the like. April 5.

VII. ACIDS, ALKALIS, AND SALTS.

[A.] 7856. Lester. Lime briquettes. April 2.

„ 7870. Pauling. Production of nitric acid or nitric oxide from air.* April 2.

„ 7871. Pauling. Production of pure nitric acid.* April 2.

„ 8362. Bellowitsch. Manufacture of ferrocyanides from gas purifying masses or other ferrocyaniferous masses.* April 6.

„ 8364. Lee. Process and apparatus for making barium cyanide. April 6.

„ 8495. Kusel, and Deutsche Solvay-Werke A.-G. *See under* XI.

„ 8910. Lecoeur. Purification of solutions of ammonia of copper. April 12.

[C.S.] 6798 (1905). Garroway. Recovery of magnesium sulphate obtained in the production of acetic acid from magnesium acetate. April 11.

„ 7916. (1905) Driffield, and United Alkali Co., Ltd. Purification of sulphuric acid. April 19.

„ 16,929 (1905). Raschen, Wareing, and United Alkali Co. Separation of arsenic from arsenical sulphuric acid and obtainment of arsenious chloride. April 11.

„ 16,930 (1905). Raschen, Wareing, and United Alkali Co. Production of arsenious acid from arsenious chloride. April 11.

„ 17,887 (1905). Raschen, Conroy, Wareing, and United Alkali Co. Production of arsenious acid from arsenious chloride. April 11.

„ 22,225 (1905). Feldkamp. *See under* XX.

„ 24,733 (1905). Roberts. Manufacture of hydrochloric acid. April 19.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 8888. Marks (Theisen et Cie.). Method of obtaining moiré effects on glass.* April 12.

[C.S.] 6816 (1905). Carl. Glass substitute. April 11.

„ 10,833 (1905). Heller, and Porzellanfabr. Ph. Rosenthal und Co., A.-G., Filiale Kronach Ceramic ware. April 19.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

[A.] 7927. Gordon. Manufacture of bricks. [U.S. Appl., May 4, 1905.]* April 2.

[A.] 8545. Rümp. Manufacture of artificial stone. April 9.

„ 8627. Crowley and Payne. Fireproof or heat resisting surfacing composition or cement.* April 10.

„ 8995. Ford. Manufacture of artificial stone. April 14.

[C.S.] 6536 (1905) Ross. Imitation marble. April 11.

„ 14,709 (1905). Walden. Asphaltic cement. April 11.

„ 1111 (1906). Pirsoul. Manufacture of tiles. April 11.

„ 1325 (1906). Poulsen. Preservation of wood. April 11.

X.—METALLURGY.

[A.] 7876. Bagley, and The South Durham Steel and Iron Co., Ltd. Open hearth furnaces. April 2.

„ 7892. Picaud. Manufacture of steel.* April 2.

„ 8084. Valentine and Betts. *See under* XI.

„ 8141. Abelspies. Ore separating tables. April 4.

„ 8507. Hunter. Conversion of iron into steel or malleable iron.* April 9.

Official Notices.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. Full particulars will be announced later.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Eustace Carey has been nominated to the office of President under Rule 8; Dr. E. G. Love, Mr. A. Gordon Salamon, and Mr. Chas. Wightman have been nominated Vice-Presidents under Rule 8; and Dr. E. Divers, F.R.S., has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's office, at least one month before the date of the Annual General Meeting, at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

ALTERATION OF BY-LAWS.

With a view to facilitate the voting of members residing abroad, notice is hereby given, in accordance with Rule 35 of the By-laws, that the Council will propose to the forthcoming Annual General Meeting the amendment of the Society's By-laws as follows:

1. Rule 18. (*a*) That the words "At least two months before the date of each Annual General Meeting," in the first and second lines thereof, be replaced by the words, "In the second issue of the Society's Journal for the month of April in each year."

(*b*) That the words "date of that meeting," in the fourth line thereof, be replaced by the words "Annual Meeting next ensuing."

(*c*) That the words "At least one month before the date of;" in the sixth line from the end thereof, be replaced by the words "not later than the last day of May prior to."

2. Rule 19. That the words "at least five days before the commencement of the said meeting,' in the two last lines thereof, be replaced by the words, "in the second issue of the Society's Journal for the month of May."

Death.

Griffith, R. W. S., of Eyeworth Lodge, Lyndhurst, Hants. March 29.

PROCEEDINGS

OF THE

EXTRAORDINARY GENERAL MEETING,

MARCH 27TH, 1906.

An extraordinary general meeting of the Society was held on Tuesday, March 27th, 1906, at the house of the Society of Arts, John Street, Adelphi. Dr. E. Divers, F.R.S., President, took the chair at 3.30 p.m.

Mr. C. G. Cresswell (Secretary) read the notice convening the meeting as follows:—

"Notice is hereby given that an Extraordinary General Meeting of the Society will be held at 3.30 o'clock, precisely, in the afternoon of Tuesday, the twenty-seventh day of March, 1906, at the House of the Society of Arts, John Street, Adelphi, W.C., by kind permission of the Council of that Society, with the object of considering and adopting the resolution mentioned in the Requisition hereinafter set forth:—

"To the President and Council of the Society of Chemical Industry."

We, the undersigned Members of the Society of Chemical Industry, hereby request that, in accordance with By-Law 40, you will convene an Extraordinary General Meeting of the Society with the object of considering and, if approved by the said Extraordinary Meeting, of adopting the following resolution (that is to say)—

Resolution.

"That it is desirable that the Society of Chemical Industry as now existing should be incorporated under and subject to the grant of a Royal Charter and that the Council be and hereby is authorised to take all necessary steps to procure the grant of a Royal Charter of Incorporation.

Dated this twenty-second day of December, 1905."

The Chairman. The business before us to-day need take but very little time, and the sparse attendance may be regarded as evidence that the members are in accord with those who have signed the requisition for this meeting. In order to shorten the business, and to put us in order, I will ask Sir Boverton Redwood to formally propose the resolution. Sir Boverton Redwood has been acting as the Chairman of a Committee appointed some considerable time ago to consider the expediency of obtaining a Royal Charter, so that he is particularly well fitted to move the resolution.

Sir Boverton Redwood. As you, sir, have already indicated in your opening remarks, this question of obtaining a Charter of Incorporation for the Society of Chemical Industry has received the attention of the Council of the Society from time to time during, I think, the past three years, and a Special Committee was appointed for the purpose of studying the subject in all its aspects, with the help of our hon. counsel, Mr. C. C. Hutchinson, to whom I would like to take this opportunity of saying we owe very much in this matter, and under the experienced guidance of our legal adviser, Mr. Markby, whom I am happy to see with us to-day. It surely is scarcely necessary for me to say very much in respect to the advantages which would result to the Society from obtaining a Charter of Incorporation. At the present time we are but an aggregation or association of persons having like objects in view, but without legal existence as a corporate body. Consequently in making representations to the Government, or in taking in point of fact any action such as is ordinarily taken by corporate bodies, we have to act simply as an assemblage of individuals with all the obvious disadvantages attendant upon such informal constitution. There can be, I think, no question that if we were to obtain this proposed charter the Society would be placed on a far higher plane in public estimation, lustre would be added to its name, and we should be in an infinitely better position to carry out the important duties with which we are charged. We should also incidentally place ourselves in a position similar to that of the other learned Societies, and it seems to be obvious that in such a position we should be far better able to advance the interests of manufactures and science.

The supremely important question of the possible effect which incorporation might have upon the status of members beyond the seas has been attentively discussed by the Committee, and I may say at once that no action would have been proposed which, in the opinion of the Committee, was in the slightest degree likely to place those members in a less advantageous position, or in any way to weaken the ties which so happily bind us together.

But on that point we are quite satisfied. We have received the most positive assurances from our competent legal advisers that under a charter the Society would be no less broadly Anglo-Saxon and cosmopolitan than it is at present, and that nothing would occur in connection with the incorporation to modify the existing constitution of the Society, so as to impair its usefulness. In these circumstances it scarcely seems that there can be room for doubt as to the advisability of passing the resolution which is before the meeting, but, as you will have gathered from what has taken place, the Council has, doubtless in the exercise of a wise discretion, preserved a passive attitude in this matter, and has not taken action until it was called upon and compelled to do so by the receipt of the requisition which has been read to the meeting. That requisition, as you will have seen, bears the signatures of representatives of all ranks and various sections of the Society; past and present officers, and many distinguished Canadian and United States members of the Society, but I should like to state that by some mischance one of the sheets bearing signatures from New York went astray. Through Dr. Power we are in receipt of a letter from Mr. Parker explaining that the signatures which I am about to give you were affixed to the requisition in his presence, and it is strongly desired that those signatures should be recorded with his own, that is, with Mr. Parker's as advocating the Charter. The signatures in question include those of the two American Past Presidents, Prof. C. F. Chandler (of Columbia University), and Dr. W. H. Nichols; the Hon. Local Secretary, Dr. H. Schweitzer; the Hon. Treasurer, Mr. R. C. Woodcock; Mr. T. J. Parker, Dr. R. W. Moore, Dr. E. G. Love, and Dr. Leo Backeland.

We have thus, besides the signatures received from Canada through Mr. E. Grant Hooper, signatures received through Dr. Power, from New York, New England, Philadelphia, Washington, Baltimore and St. Louis. On receipt of the requisition the Council called this meeting, and, although it was recognised that members not resident in the United Kingdom could hardly be expected to attend, time has been afforded for the receipt of written expressions of any views that might be entertained. As bearing upon the question of the New York signatures, and as indicating the opportunity there has been afforded for the conveyance of expressions of opinion, I may, perhaps, be allowed to read this very brief letter, dated March 6th last, from Mr. Parker to Dr. Power:—

"I am glad to receive your valued letter of the 23rd ult., and to learn that there is a prospect of the names sent you as advocating the acquisition of a Royal Charter for the Society of Chemical Industry being added to your list. I know this would be pleasing to both Mr. William H. Nichols and Prof. Chandler, as I spoke to both these gentlemen personally about it, and they were both very much in favour of it. I shall be glad to learn that Sir Boverton Redwood has appended the names to the list. Please let me hear from you.

"Yours very truly,
"(Signed) T. J. PARKER."

Perhaps it may be anticipated that before resuming my seat I should say a few words as to the prospects of success in the event of the resolution being carried. Obviously nothing like an assurance can be given on such a question, but I think I am justified in stating that the results of confidential inquiries have been such as to give us the most hopeful anticipations of success. I have only further to say that if there are any points that I have not covered in these remarks, on which any member of the Society here present would like to have additional information which it is within my power to give, I hope he will address himself to the Chair on those points, and I have only now in conclusion to formally move the adoption of the resolution which is incorporated in the notice convening the meeting which has been read by the Secretary.

Mr. A. GORDON SALAMON: I have been asked to second the resolution which has been so well described to you by Sir Boverton Redwood, and have very great pleasure in doing so. No one who has served on the Committee, and who has studied this question, can have the slightest doubt that the obtaining of a Charter of Incorporation must react for the benefit of the Society as a whole, and must tend to consolidate those sections beyond the seas with our sections at home. If this be so, it will have the ultimate effect of rendering our Society the most powerful of its kind, and of making it represent fully and completely the chemical industries so far as they are controlled by English speaking chemists.

The CHAIRMAN: I invite discussion on this motion before putting it formally to the vote. Whilst as Chairman of this meeting I wish to preserve an impartial attitude, I believe I may as an individual, without overstepping my position as Chairman, say that I am very strongly in favour of getting this Charter. As you know, this Society has grown very large, and, in consequence of its numbers and importance, it has ventured in recent years to make itself heard on questions of public importance in relation to chemical industry. Now, if any case of strenuous opposition—such as might be offered by vested interests in such a case as is now before a Royal Commission, that of the utilisation of the canals and waterways of this country—to what would be an advancement of chemical industry, I think the Society would feel much greater confidence in combating this opposition, if it knew that it had behind it the position given by the possession of a Royal Charter. At any rate, it would not have to vindicate its right to be heard. Again, were any movement intended on the part of the Government to advance scientific interests, and those societies representing them, we should, if we were a chartered Society, have a much better claim to receive consideration than we have at present. Some 50 years or more ago this question did arise, when the Government, which had already given accommodation to the Royal Society at Somerset House, decided to give further housing accommodation to this and other scientific societies, it limited the housing to those only which had a Charter. If, therefore, we had been then in existence we should have received no consideration whatever from the Government. No doubt other cases may turn up in which we may find the advantage of the consideration which would be given to us from our possession of a Charter. I now invite remarks for or against this motion.

Mr. R. J. FRISWELL: I gather from a remark which fell from Sir Boverton Redwood that the Council adopts a passive attitude in this matter. We have heard most eloquently from him, from Mr. Salamon, and from the Chairman, the advantages which would accrue from the possession of a Charter, but there are a certain number of disadvantages which also accompany it, and I think it is right that those also should be borne in mind. After all unless we act upon the theory that silence gives consent, the signatures to the requisition, and the members present do not amount to much more than 1 per cent. of the Society, so that it appears that there are a considerable number who maintain silence, which may be that of consent, of simple neutrality, or of want of information. Now I happen to be one of the survivors of a very embittered discussion which in the years 1874, 1875 and 1876 shook the Chemical Society very nearly to disintegration. It arose from the fact that numerous persons without any pretence to a knowledge of chemistry were making use of the letters "F.C.S." in order to advertise themselves as competent chemists, and to obtain practice on that ground. Amongst the members most prominent in the discussion were the late Dr. Wright, Prof. Hartley, and Mr. C. T. Kingzett, and several others, including myself. We appealed to the Chemical Society to know whether it was possible that some evidence of qualification for membership of the Society could be required. At first the Society was extremely averse from giving any reply at all; but at last, after a deal of discussion, they agreed to refer the matter to counsel. Counsel referred to the Charter, and advised them that under the Charter it was absolutely impossible for the Chemical Society to require from candidates any knowledge of chemistry—it was simply necessary for a person to be recommended by a certain number of Fellows and to declare that he took an interest in chemistry, and if he were elected and able to pay the fees he became

a Fellow of the Society. Finding it impossible to carry this point, we went further and asked the Society to see whether, under the Charter, they could amend their rules and get a separate class of Fellows established. That proposal I believe arose on the motion of the late Sir Edward Frankland. The matter was referred to counsel again, and again to the Charter, and again it was announced that they had no power whatever to effect any alteration, and that, moreover, any attempt to alter the Charter would rouse opposition, and in addition to being very costly financially might possibly cause other injury to the Society. The result, as we all know, was the formation of a separate body, the Institute of Chemistry. Later on, when I was a member of the Council of the Chemical Society, it was proposed to admit ladies. The Council debated the matter several times, and there was a strong feeling on the part of a majority that ladies should be admitted to the privilege of Fellowship, but again the Charter was referred to, and again it was found impossible. I have referred to these matters simply because the possession of a Charter, like other questions, has two sides to it. Although it undoubtedly, as the proposer and the seconder have stated, confers considerable powers on the Society, enables it to own property, and to do many acts which it otherwise could not do, and also confers prestige, yet it undoubtedly seriously hampers every Society, because I am informed, and I had a great deal to do with the question of the Charter that the Institute of Chemistry obtained, that when a Charter is once granted you are not in the position that you are in under the ordinary law—where you may do that which is not forbidden. When you are under a Charter you may not do that which is not forbidden, you may only do that which is expressly permitted in the Charter. Therefore, unless we are to become to some extent stereotyped or fossilised, it will be necessary for the proposed Charter to be drawn with the most extreme care if future expansions and alterations of the Society may be permitted without having recourse to that tribunal which both the Chemical Society and the Institute of Chemistry have looked upon with considerable alarm, that is the Privy Council, for an amendment of the Charter. As to the possibility of the Society being granted a house, because it is a Chartered Society, I do not think there is much force in that. When a house was granted to six learned societies there were, I believe, but six. Now there are numbers of societies—there are Chartered Accountants, Chartered Patent Agents, the Institute of Chemistry, and various other Chartered Societies, and I do not think it is in the least likely that public money will ever be expended on granting houses to any of those bodies which are to some extent, as we are, of the nature of professional or trade societies.

Gentlemen, I have only made these remarks because I felt it my duty to do so. I have seen during 27 years past the very great difficulty which the existence of a Charter places in the way of a Society which is a living and expanding body. It is all very well for the Chemical Society to have its Charter, but in my opinion it has stereotyped a great many points which could be very well improved. It is all very well, also, for the Institute of Chemistry, which is an examining and qualifying body, but in a body such as ours I feel sure there are likely to arise occasions when it will be desirable to go outside the Charter, however well it may be drawn. We cannot foresee what changes may arise in a few, even 20 years' time. You may say, sufficient unto the day is the evil thereof, and draw our Charter as well as you can, but I hope, as the Council of the Society have taken a passive attitude in this matter, they will at any rate carefully consider what may arise in the way that I have mentioned before proceeding to take a step which, it seems to me, must tend to stereotype our Constitution for, at any rate, a great number of years to come.

Mr. T. Tyrer: I do not propose to follow Mr. Friswell in his rather alarmist speech. I have inquired into the points mentioned by him and may say, for his comfort, that the answers to questions put to the solicitor of the Committee have completely removed my own doubts and fears. May I remind you that the Society's Constitution is extremely broad and wide. The objects of the Society are not such as in any way to be taken as quasi professional, nor can membership be regarded as in any degree a qualification. It may be that the value of membership of the Society of Chemical Industry, apart from its Journal, is that it is a Society of good fellowship, and that wherever a member of the Society meets another there is at once instituted a bond of friendliness and friendship which goes far to justify the application for this Charter. It must not be taken, I think, that the use of the word "passive" as regards the Council is in any way to be regarded as implying dissent. The passivity of the Council is an obligation, as well as a wise action on their behalf. This question was raised some time ago, and has been referred to more than once. I retired from the Council last year, and up to that time the attitude, though passive, was entirely friendly and satisfactory. From time to time to my knowledge, by definite reports, the Committee told the Council what was going on. Most careful questions as to the existing by-laws, based on the fact that this is a Society of wide membership, extending over all parts of the world, questions as to nationality and government and proceedings of various sections have been put—most trying and most interesting questions have been put—to the legal advisers, and I have heard satisfactory replies. But these thoughts were not in my mind until Mr. Friswell spoke. What I really rose to say was this. In addition to the names which have been added, and to which Sir Boverton Redwood referred, there is this great fact, that in one's visits to America within the three years referred to, there were no objections, there was no "passive" resistance, there was no criticism; everybody was pleased, particularly when answers were given by those who knew the spirit in which this movement was commenced. During the meeting which took place last year, the expressions of confidence in the Council, and hopes for the future of the Society, and belief in its great mission, were very numerous and hearty. Out of the very large number of letters I have received, in a majority of them reference was made to the coming action, and hopes expressed that whatever steps might be taken by the Council would be for the good of the whole Society, coupled with the assurance that they were quite convinced that such a Council as we possess could do nothing which was very far wrong. I simply want to emphasise the fact that we need have no fear as to the paucity of members attending now being used as an argument against us at any time. Members could have written, they have had plenty of opportunity, and if there had been any opposition we might have been flooded with telegrams from various parts of the world, especially from America, where they are not shy in expressing opinion. That has not happened and is, therefore, a very happy augury for the future.

Mr. Julian L. Baker asked, in the event of a Charter being obtained, if it would be possible at any future time to raise the annual subscription to the Society?

Sir Boverton Redwood: On that point the solicitor has explained to me that it is not intended to specify the subscription in the Charter, and therefore it can be fixed from time to time as the Council may think fit.

Mr. E. Grant Hooper thought that both Mr. Baker's question and the remarks of Mr. Friswell pointed not so much to the disadvantage of a Charter as to the necessity of securing broad powers. That, he felt, was really the purport of the remarks Mr. Friswell had made.

Mr. Friswell: Certainly.

Mr. E. Grant Hooper: With that view he was sure they were all in sympathy. They did not desire to bind themselves in any narrow groove; and he himself felt that every effort should be made to obtain a Charter of as wide a character as possible. It was impossible to forecast the future of a Society such as this, and just as the various developments which had occurred in the course of its existence could scarcely have been foreseen at its foundation, so was it undesirable that they should limit themselves in any avoidable manner as regards the future. That there might be some limitation, even

after every care was taken, was, he thought, only to say that this, like most other propositions, was not absolutely free from disadvantages. They could hardly hope to escape that, but what had to be considered was whether or not the balance of advantage was in favour of the direction in which they were proposing to proceed. On that point he thought that the comparative smallness of the meeting was evidence of a general feeling on the part of the Society as a whole that they were moving in the right direction.

Mr. DAVID HOWARD: I am not a lawyer; but may I suggest that even as an incorporated body under a somewhat cumbersome Act, we are still limited in our powers. We cannot go beyond our memorandum. If we wished to make some fundamental alteration we should have a process almost as cumbersome as obtaining a Charter to go through, and is there not an advantage in having clearly defined objects and sticking to them? I am old enough to remember the whole history of the discussions at the Chemical Society about practising Fellows. I was an enthusiast at that time in favour of it, and I am bound to say I think it was one of the best things that ever happened that we had a Charter to prevent our making a mistake. It has been much better that the Institute of Chemistry should do the work, and not act as a mere adjunct to a learned Society which had nothing to do with professional work as such. Therefore I think that is one thing distinctly in favour of a Royal Charter. Again, with regard to the admission of ladies, I do not think that the injury to the Society has been so serious as to justify that being claimed as an objection to a Charter; and we can put in words which will prevent our excluding ladies. Then, with regard to the Institute of Chemistry, I do not know of a single point in which the Charter has done us any harm, and I know many in which it has done us good. The very fact that it has kept us on strictly defined lines—not too strictly—has been a great benefit to the Institute. I have heard some wild suggestions, and there is no more delicate way of suggesting to a man that he cannot have what he wants, than to say that it is not in the Charter; it is so much more considerate to put it in that way than to say "you know it *is* very stupid"; and very often that would be the only alternative. I have had a pretty long experience as a Fellow of two Chartered Societies, and have found it an unmixed blessing. After all, it ever so fundamental a change was proposed as to go outside a carefully-drawn Charter, I think it is very well to make it extremely difficult, and make it require very careful and serious consideration before you do it. We have a certain check on us now, and if the other check is somewhat more severe, is it unwise to have that check? Is it unwise to prevent some rash action which would do away with the useful work of many years? For it is far from certain that progress is always in the right direction. When I was young I learnt Latin, which I believe now is objectionable in a chemist, and I was taught a certain line about an extremely easy descent to a place which we do not mention. Therefore progress may be in a wrong direction. On the other hand, a difficulty in making fundamental changes is an unmixed good.

Mr. P. MACEWAN: If this resolution is passed, will it be final? I ask that because I notice that the British Medical Association are also going to apply for a Royal Charter, and the first thing that Association seems to have done was to submit to its members the draft of the Charter. From that I learn—and the thing is brought to my mind by Mr. Baker's question—that their subscription is the same as ours, but in the Charter they say that the subscription shall not exceed 60s. a year. My question is, will the members of this Society not have an opportunity of reading the draft Charter before it is applied for? If it were published in the Society's Journal, some suggestions might be put forward by members who took care to read it.

Sir BOVERTON REDWOOD: The answer is that all that this meeting would commit the Society to is indicated by the resolution; and with respect to further action, the course which would be taken would be to submit the byelaws, which in effect would indicate the nature of the Charter to the members of the Society, at a subsequent date, for their consideration and approval; when further opportunity, of course, would be afforded for discussion of the subject.

Mr. MACEWAN: Before, or after the Charter is obtained?

Sir BOVERTON REDWOOD: Subsequent to the granting of the Charter. What this Society would be committed to is indicated by the resolution; namely, that the Council is authorised—assuming this resolution to be passed—to take all necessary steps to procure the granting of a Royal Charter of Incorporation. The Council, in pursuance of that authorisation, would proceed to take those steps. Assuming that they meet with success, and obtain the Charter, it would then be necessary to draw up a series of byelaws, which, as I have said, would be submitted to the Society in due course for their consideration and approval.

Mr. MACEWAN: Why should not we have the same advantage as in the case of the British Medical Association, where the proposed Charter is submitted to all the members and published in the Society's Journal? I simply throw that out as a suggestion; I do not press it, but it struck me as being an exceedingly good idea to let members see what is exactly being asked for.

Sir BOVERTON REDWOOD: I take it, Mr. President, we are perfectly safe in acting as I have indicated. We are acting under the advice, and with the experienced assistance of Mr. C. C. Hutchinson and of Mr. Markby; and I may further point out that it would not be, as I understand, the constitutional method of procedure to discuss the terms of a Charter which we may never obtain. We have first of all to procure the Royal recognition, which is indicated by the granting of a Charter. It is possible we might not get precisely such a form of Charter as we might have in our minds as the outcome of discussing the particulars of the Charter by a meeting.

The CHAIRMAN: Are there any other remarks to be made? If not, I will ask Sir Boverton Redwood to reply to the comments which have been made, in so far as necessary.

Sir BOVERTON REDWOOD: I have only to say that I think we are indebted to Mr. Friswell for his attendance here, and for the remarks he has made; first, because it is always well to hear both sides of a question, and I may say that one admires a man who has the courage to express himself in a sense which may perhaps be different to that of the majority of those among whom he finds himself for the time being. But especially I think we are indebted to Mr. Friswell because his remarks have had the effect of eliciting speeches in support of this motion which perhaps otherwise we might not have had. There is, I think, in all that Mr. Friswell has said, only one point for me to comment upon. Mr. Friswell has alluded to the size of this meeting, on which I have nothing further to say beyond what the Chairman has already remarked; but I ought to refer in connection with that to the comparatively small number of signatures to this requisition. Coupling the paucity of this attendance with the small number of signatories, Mr. Friswell pointed out that, collectively, it represented but a small fraction of the total membership of the Society. It is only right for me to say that with respect to the signatures for this requisition, all that was aimed at was to comply with byelaw 40, under which the requisition was sent in and this meeting has been called, which byelaw requires that there shall be at least thirty signatures. It was, in fact, rather by accident than by intention that we exceeded the requisite number. It was in point of fact in taking steps to obtain only the requisite number of signatures that something like double that number came in. But I know that there would be no difficulty in indefinitely, within the limits of the membership of the Society, extending the list, and, therefore, it must not be taken that the number of signatures has any kind of bearing whatever on the attitude of the members of the Society in relation to the proposition which has been put before you.

The CHAIRMAN: I most cordially endorse the words of Sir Boverton Redwood in thanking Mr. Friswell for expressing some words of warning to us as to the steps that we are proposing to take. It is very important for this meeting to consider both sides of the matter, so that we may not be deciding without having considered the consequences. Mr. Howard has treated the matter so thoroughly from the point of view I take myself, that it is unnecessary to enlarge upon what he has said. I may mention that I also was in the fight at the Chemical Society to which Mr. Friswell referred, and which led to the foundation of the Institute of Chemistry. Similarly, some remarks made at a meeting of the Chemical Society in the discussion of an important paper by Mr. Deacon, led, indirectly, to the foundation of the Society of Chemical Industry. A wish was then expressed to enlarge the scope of the Chemical Society's operations, so that industrial chemical papers might be read there as well as purely scientific ones. I am sure that on these two occasions the Chemical Society found such shelter as its Charter afforded rather helpful, for it was felt by many of its Fellows that such great undertakings would prove to be beyond the ability of the Society to carry through. As was mentioned by Mr. Howard, a Charter is really very useful at times in this way. If we find out after we have got the Charter any sufficient reason for wishing to extend or modify our powers, it will probably not be difficult or expensive to get a modification of it, or a supplemental Charter. I think, therefore, that we should not be frightened by the dangers which Mr. Friswell has brought before us, although it is important that they should be taken into consideration. I do not think it is amiss for me to express the hope that Mr. Friswell will hold up his hand in favour of applying for the Charter, although, very properly indeed, he has thought it well to point out the objections there may be to doing so without due precautions.

Dr. POWER: Before you put the motion, Mr. Chairman, I should like to say a word. It seems to me that in connection with the record of the proceedings of this meeting it is desirable that there should be some expression of sentiment with regard to the bearing of the Charter on the *status* of the members of the Society across the seas. I naturally have, so far as the United States members are concerned, a feeling of deep interest with regard to this matter, and I think I may say that this movement has received the unqualified support, and the deep sympathy of the more influential members in the United States. The only hesitation that seems to have been expressed in connection with this matter, is as to whether the *status* or the relations of the members in the United States would in any way be prejudiced or altered by the granting of a Royal Charter to this Society. They have received definite personal assurances that such would not be the case, and, if I remember rightly, Sir Boverton Redwood has referred to this in the course of his remarks. I think we may take it for granted that the Charter, if secured, will be drawn on such broad lines as to guarantee the equal rights and privileges of every member of the Society in any part of the world.

The CHAIRMAN: I am sure we are much obliged to Dr. Power for what he has said.

Mr. S. HALL: One thing has occurred to my mind which may induce Mr. Friswell to think of altering his view, though I do not know which way he is going to vote. He has very wisely made us think how to keep the Charter as wide and broad as possible, because Charters no doubt do have the effect of limitation in certain cases; but would it not be the same thing if, having the probability of obtaining a Charter, we limited ourselves and so did not obtain those advantages which Mr. Friswell himself thinks would accrue from it? We should be depriving ourselves of the opportunity of getting them if we did not accept or take the Charter.

The CHAIRMAN: There is one point I forgot to mention just now, and that was with regard to the question raised by Mr. MacEwan. I should like it to be clearly understood that, in applying for a Charter, we are not applying for any modification of the laws and constitution of the Society. As it has been explained by Sir Boverton Redwood, the byelaws will need some revision when we have got the Charter. Any changes will have to be authorised by the vote of a General Meeting of the Society.

I will now put the matter to the vote. Those in favour will please signify the same in the usual way.

It is carried unanimously.

The CHAIRMAN: It only remains to thank you for your attendance to-day.

Mr. S. HALL: Allow me a moment. I am sure that all those who have had anything to do with this matter during the years it has been under consideration must wish to thank Sir Boverton Redwood for the very great care he has exercised, for getting the very best information for us, for calling us together, and consulting us, not only the Committee but the Council, about it. I therefore propose a vote of thanks to Sir Boverton Redwood.

Mr. WALTER REID: This is a resolution which probably everybody in the room would like to second, and if I may claim the privilege of doing so, I would like to, knowing as I do the large amount of work Sir Boverton Redwood has done. This matter has been before us about three years, and during those three years, although it has not been published generally to the Society, the Council have had many reports on the matter, and nothing could equal the clear method with which Sir Boverton Redwood has treated the subject. I do not think one false step has been made from the beginning. When difficulties presented themselves, they were met, and the result is highly satisfactory, and we are much indebted to Sir Boverton Redwood.

The CHAIRMAN: Again, if I may exceed my duties, I should like to take sides and strongly support this resolution, because I feel that nothing that has been said by the proposer and seconder has gone beyond the facts of the case.

The resolution was put and carried unanimously.

Mr. DAVID HOWARD: There is another resolution I should like to move. Our President is only our Chairman to-day, and the Chairman may have a vote of thanks. We the more welcome the opportunity of thanking him, because, as President, we have so much less opportunity of doing so, although, whether as President or Chairman, we are glad to be presided over by him.

Mr. GRANT HOOPER: I beg to second that.

The resolution was put by Mr. Howard and carried unanimously.

Sir BOVERTON REDWOOD: Before the Chairman rises to respond to the vote proposed by Mr. David Howard, may I say that while I am deeply grateful to the Hon. Treasurer of the Society, Mr. Samuel Hall, and to my friend, Mr. Reid, for the very kind words which have fallen from them, and to my friend, Dr. Divers, for supporting the motion, I nevertheless feel that I am placed in a somewhat uncomfortable position. I recognise that we are very far as yet from having achieved the object we have in view, and I cannot help thinking that if, in the end, we should chance to be unsuccessful—I do not anticipate we shall be, but these things do occur—I should deserve your execration rather than your praise. Therefore I cannot divest myself of the idea that perhaps in a sense this motion is a little premature. Let us wait, please, until we have accomplished that which we have in view, and then if you think the work has been well done, I shall be only too glad to hear it.

The CHAIRMAN: I thank you for the kind way in which you have passed the vote of thanks to myself, for your attendance here, and for having done a public duty to the Society. If everybody had stayed away, satisfied that even in their absence the matter would be determined as they wished, nothing could have been done till another meeting had been called.

Birmingham Section.

Meeting held at Birmingham, on Thursday, March 15th, 1906.

PROF. FRANKLAND IN THE CHAIR.

NOTE ON A SIMPLE METHOD OF CHECKING THE EFFICIENCY OF A SEWAGE PURIFICATION WORKS.

BY F. R. O'SHAUGHNESSY, A.R.C.SC., F.I.C.

It is always desirable, and in most cases it is necessary, to have some working standard for guidance in the construction and manipulation of plant to be used for purifying sewage. The moment one attempts to fix definite limits, however, one is met by a number of not inconsiderable difficulties; and at least any arbitrary figures which may be adopted can have only a local and special value, which, if rigidly adhered to, must often give rise to grave anomalies. It is, however, not merely a matter of considerable interest, but it is of the utmost importance to know what may be considered a reasonable degree of purification in any given sewage. For the grosser impurities are usually eliminated with comparative ease, but as the liquor gets purer, it becomes more and more difficult, and consequently more and more expensive, to remove a given increment of impurity. When the process of purification has reached the stage when the purity of the liquor approximates to that at which it is usually considered wise to fix a standard figure, a slight increase in the stringency of the standard will entail an enormous, and often an altogether disproportionate increase in the cost of the sewage works. Taking this fact into account, and remembering also that our ideas on some of the important aspects of this question are necessarily tentative, it behoves us to avoid the besetting sin of dogmatism. The promised land of finality is not for this generation of sewage experts, and it is manifestly absurd to spend large sums of money in effecting what may be an unnecessary degree of purification. It is not my intention in this brief note to discuss at length this vexed question of standards, but my own experience would suggest an elastic rather than a rigid standard, as being the more reasonable.

The object of this communication is to bring forward my deductions from some of my observations on the effect of sewage effluents on the water of the river into which they are discharged. A reasonable condition, as will be generally admitted, is, that the effluent shall *at least* not cause the water of the stream to deteriorate. This condition seems so obvious, that it is often and easily quoted as an axiom. But be it noted that, while it is easy to quote an aphorism, it is somewhat difficult to devise a ready working means of checking this condition The method I am about to explain is as simple and obvious as the axiom. It consists in determining the tendency of the river water to putrefy above and below the given sewage works. As a control, isolated comparisons are of little value, as the river water in populous districts is so extremely variable in composition.

In my own experiments, the observations were made almost daily, and in the table the results are given for a whole year.

AVERAGE analysis of the Rivers Tame and Rea in dry weather.

Results expressed in parts per 100,000.

Sample.	Albuminoid ammonia.	Oxygen absorbed in four hours.
River Rea (above works) ...	0·102	0 913
River Tame (above works)..	0·114	1·172
River Tame(Sweetmore Bridge) (Rea and Tame combined below works).....	0·121	1·233

Also for comparison I give the average analysis of the river water in dry weather, both above and below the works.

The tendency of any particular sample to putrefy was determined by the well-known "oxygen absorbed in three minutes" test, applied before and after incubation for five or six days.

The point to be noted is, that though the water tends to putrefy below as well as above the works, the number of samples showing putrefactive tendencies is less, in this case, below the works than above. This, therefore, may be considered satisfactory, and the works in question, from the point of view of this condition alone, are working efficiently. If the samples showing putrefactive tendencies were more numerous below than above, then the reverse would be the case. This condition is an extremely important one, and anyone familiar with the great difficulties to be surmounted in the treatment of enormous volumes of impure liquid will realise how severe is a control such as this.

Nevertheless, that such a standard can be maintained, the figures amply demonstrate. Further, the observations have that superlative advantage from the point of view of the layman in that they are on a practical and not on a laboratory scale. This method should form, therefore, a very good working test.

DISCUSSION.

The CHAIRMAN said, as Mr O'Shaughnessy had remarked, the tendency now-a-days was more and more to do away with hard and fast standards of sewage purification and to consider local circumstances. It was obvious that to purify sewage which was to be discharged into a foul stream and to purify sewage which would pass into a stream afterwards used as drinking water were two very different matters and it would be unreasonable to employ the same standard for both. This test, which Mr. O'Shaughnessy had introduced, was a very luminous one. The layman could easily understand it. It was based wholly upon practical results. It did not deal with the amount of organic matter—albuminoid ammonia, or anything of that kind, but simply with the question of whether the water putrefied or not after incubation in a closed bottle at a certain temperature for a certain length of time. It would have been advantageous if Mr O'Shaughnessy had stated the amount of nitrates at the three places in question—the Rea, and the Tame at Saltley above the works, and the Tame at Sweetmore Bridge below the works—this diminution in the putrescibility of the water below the influx of the sewage effluent was no doubt to be attributed to the nitrates present

STATEMENT of the condition of the Rivers Tame and Rea at Saltley (above Drainage Board's works) and river Tame at Sweetmore Bridge (below Drainage Board's outfall).

Percentage of samples analysed which showed signs of putrefaction.

in the sewage effluent. There was only one point to guard against, *viz.*, the effect of any other stream entering the Tame.

If Mr. O'Shaughnessy said there was no further tributary between the entry of the Birmingham effluent and the spot where his samples had been taken below, then these figures clearly showed that the character of the water was *chemically* inferior after the introduction of the sewage effluent. The albuminoid ammonia had gone up; the oxygen absorbed had also gone up, but in view of the very considerable proportion of nitrates introduced into the stream in the effluent, the purification of this organic matter which had been introduced, took place because the oxidation of this organic matter was effected at the expense of the nitrates. It was very convenient when one had to discharge a sewage effluent into a foul river like the Tame and Rea and not into a pure stream, because it was comparatively easy, by means of a sewage effluent, to purify a foul river like the Tame than to do the same in the case of a beautiful upland stream.

A similar case occurred to him at Manchester, where the effluent from the sewage works was discharged into the Manchester Ship Canal, which he supposed was about the foulest water that could be found in the United Kingdom, and it was an easy matter there to discharge an effluent which could be shown to purify the Manchester Ship Canal rather than pollute it.

Dr. A. Findlay criticised the method adopted in taking the average for the whole year, as the variations in the different months were so great; could not one, perhaps, get a better idea of these results by plotting in a curve—putting each month by itself? He did not care for the idea of lumping all the figures together for the year, because the irregularities were so great in the different months.

Mr. A. E. Tucker asked whether the very marked difference in the putrefaction figures attributed to June and July could be attributed to climatic influences—whether June was cold and July hot—or how otherwise they could be accounted for.

He also asked for further details as to the actual method. The time for the permanganate test was given, but not the time for the subsequent incubation.

Mr. H. Silvester said the question was a very important one for a densely populated district like the Midlands. Frequently it was very little credited in rural districts. He believed the County Council of Derbyshire had a fixed standard of 0·1 albuminoid ammonia and 1·0 of oxygen absorbed in parts per 100,000. That was very well for Derbyshire, where there were no very large works, but in the Midlands, where a number of manufacturing industries were pouring their waste products in the sewage, it was difficult to get the effluent at the outfall works to comply with these figures; then the incubation test, which he believed was used by the Chairman in his Manchester experiments, supplied a want. If in a polluted stream like the Rea and Tame an effluent could be turned out that would not putrefy and would admit of coarse fish living, that was all that could be reasonably expected. He took it that that was the object of the figures which Mr. O'Shaughnessy had put on the board, showing that good work was being done by the Tame and Rea Drainage Board.

The Chairman said he was not the originator of the process; it was due to Mr. Scudder.

Mr. Clifford asked whether the three minutes' oxygen absorption test, before and after incubation, did measure putrescibility. In carrying out similar tests at Manchester some difficulty was experienced in deciding whether a particular sample was putrescent or not when it was on the border line of putrescibility. Some samples would be slightly putrescent, but the oxygen absorption showed no increase; others would remain practically odourless, yet showed a slight increase in the oxygen absorption. No mention was made as to the indefiniteness of the test. Had Mr. O'Shaughnessy tried the dissolved oxygen method as a measure of putrescibility? Some work had been done at Manchester by that method. Known quantities of effluent and aërated tap water were mixed and incubated, and the dissolved oxygen determined. There was one other point not mentioned, namely, the possible effects of certain tar products on the three minutes' oxygen absorption test.

Dr. T. S. Price suggested, in connection with Dr. Findlay's remarks, that, in taking an average, it would be better if the relative volumes of water contributed by the Rea and the Tame were taken into consideration. It would thus be possible to obtain a better average to compare with the results that were obtained below the sewage works.

Mr. A. H. Hiorns said the results applied specially to Birmingham, of course, and he could not see how they could be compared with other towns. How far would the acid liquors, waste pickle and so on, which must go into the sewage in enormous quantities, operate in the putrefaction? A lot of acid, he believed, also came through the special method of purification. If that method were not adopted, the same results would not occur in other districts; therefore, he thought these results were applicable to Birmingham only and could not be compared with those of other districts.

Mr. W. W. Butler asked whether it was correct to assume that the quantity of albuminoid ammonia could be ignored so long as the effluent was not putrescent. It seemed to him a remarkable statement. If he had a manufactory and wanted to make use of the stream water referred to, he would naturally look upon that indication of albuminoid ammonia as very dangerous from his own point of view. Would Mr. O'Shaughnessy say that, as the water was not putrescent, he had a good defence against the charge of contamination?

Mr. O'Shaughnessy, in reply, said his was essentially not a paper dealing with details, but with the effect, in the broadest possible way, of the sewage effluent on the stream. The questions which different speakers had raised were mainly questions of detail. As Prof. Frankland surmised, there was an increase in the amount of nitrate in the river water after receiving the effluent, but even so, if the test for putrefaction was not applied directly, there was no guarantee that the water of the stream did not possess a greater tendency to putrefy after reception of the purified sewage. After all, their deductions, however obtained, must ultimately be submitted to a number of laymen for consideration, and he had found by experience that such people did not care to be troubled with a lot of figures which they only very partially understood. The *raison d'être* of the method and the test was to supply information which could be put into plain English, and readily grasped by the average layman. It was quite true that the albuminoid ammonia and oxygen absorbed showed an increase, but that increase was very slight, and he need hardly point out that to remove this slight increment from, say, 25,000,000 galls. of water per day would entail an enormous expense. Moreover—and Mr. Butler had referred to this point—since the tendency of the river water to putrefy was lessened, they might anticipate that, with free access of air and all the purifying agencies of the stream at work, the river water would improve as it flowed along. This he actually found to be the case, and the rate of improvement was astonishing.

With respect to Mr. Tucker's query. The test consisted in observing the amount of oxygen absorbed by a given volume of the sample from acid permanganate, in three minutes, both before and after the sample had been incubated in a closed bottle for five or six days at 80° F. With regard to the months of June and July, Mr. Tucker was correct in his surmise—one was very wet and the other a dry month.

Mr. Clifford had remarked on the indefiniteness of the test, and it *was* indefinite with respect to the *amount* of putrescibility. He had, however, used the term "putrefactive tendencies" advisedly, for, although a sample might not have quite enough available oxygen to remain non-putrescent in a closed bottle, still only under very exceptional circumstances would the same water putrefy when exposed in the river. The method was not empirical

with the behaviour of any given sample, but with the general conditions obtaining over prolonged periods.

With respect to the method for determining the rate of absorption of dissolved oxygen, he had made a large number of observations, and was convinced that in experienced hands it was capable of giving very valuable information with respect to the behaviour of the dissolved contents of water. Tar products were not present in sufficient quantity to interfere here, but when present were likely to produce confusingly curious results. He agreed with Dr. Findlay's objection and with Dr. Price's remark.

Acid discharges were certainly inimical to biological treatment, if present in sufficient quantity. It was necessary, in fact, to exercise considerable care from that point of view, and at times some difficulty had been experienced owing to those waste liquors. At one time, it was thought that Birmingham sewage could not be successfully treated otherwise than chemically, but during the last five or six years the opposite had been demonstrated.

The CHAIRMAN said those results might be produced in another way. If the sewage were treated with a large proportion of antiseptic chemicals, then the number of samples putrefying below the point of ingress might be less than that of those putrefying above. Of course, that would not be a desirable state of things, because on further dilution, putrefaction would ensue. But if, as Mr. O'Shaughnessy assured them, the nitrates have gone up, then it was obvious that the smaller putrescibility of the samples below the works was due to the presence of nitrates and not to the presence of antiseptic chemicals.

Mr. O'SHAUGHNESSY said that the chemicals, in the original sewage, practically did not affect the nature of the effluent going out, because it first of all had to go through septic tanks where it was well mixed, and every drop of water to which those figures applied had to filter through an average of 4 ft. 6 in. of soil before it reached the river, so that the chemicals could not have much effect on the final effluent.

London Section.

Meeting held at Burlington House, on Monday, April 2nd, 1906.

MR. A. GORDON SALAMON IN THE CHAIR.

The CHAIRMAN said he had a very pleasant duty to perform, namely, to inform the members that their American brethren whom they had the pleasure of welcoming last summer, had sent a very charming recognition of their reception in the form of an engraved tablet, which they desired should be kept as a permanent record of the pleasure which their visit had given them. The wording was as follows:—

"The American members of the Society of Chemical Industry who were present at the Annual Meeting in London, 1905, and participated in the many splendid tours, receptions and entertainments forming the great programme provided by the London and Provincial Sections of the Society, desire to place on record in an enduring form their deep appreciation of the delightful hospitality and attention extended to them by their British fellow members.

"In expressing their thanks and gratitude the American members feel that the new and more intimate relations established with our brothers across the sea by the meeting of 1905, have broadened and strengthened the bonds of love and friendship already so firmly established between the two great English-speaking countries."

The Committee, in accepting this memento, had instructed their Hon. Secretary to write to the Chairman of the Visiting Committee in New York, saying how much they appreciated this token from their fellow members across the sea, and it was also their intention to ask the Council to allow it to be hung in their Council Room at Westminster. He trusted that would meet with the approval of the meeting.

ROPINESS IN FLOUR AND BREAD AND ITS DETECTION AND PREVENTION.

BY E. J. WATKINS.

During the hot autumnal months, bakers are frequently confronted with the outbreak of a serious disease in the bread called "rope." The disease generally declares itself within 12 to 48 hours, after the loaf has left the oven. At first, the bread acquires a faint, sickly odour, and, upon cutting open, the crumb of the loaf is found to be infected with brownish spots, larger and more numerous at the centre of the loaf. With the progress of the disease, the spots gradually expand until the centre of the loaf becomes moist and sticky. The infected portions can be drawn into long, gummy threads, hence the name of the disease. If conditions are favourable, the whole of the crumb finally becomes reduced to a slimy, brownish mass, and presents the appearance of having been saturated with molasses, emitting a strong valerian-like odour. Bread which contains bran, such as wholemeal, Graham bread, rye bread and patent bread which contains more or less of the germ and husk, is much more frequently attacked by the disease, than is bread made entirely from white flour, but the disease is not uncommon in white bread. The straight grade flours, *i.e.*, those made from the flour obtained on the break rolls, and hence more or less contaminated with the dust and bran fragments, appear to be more liable to attack than the patent grades, made from the fine clean semolina, obtained from the heart of the endosperm.

All modern writers agree in ascribing this disease to bacterial activity, but a wide difference of opinion appears to exist, in this country, as to the nature of the specific bacillus. Ropiness in liquids has been exhaustively studied by many workers, and English writers upon bread have generally attributed to organisms isolated from such solutions, the power to also produce ropiness in bread thus:—

W. Jago ("Science and Art of Breadmaking," 1895) quotes Morris and Moritz as having traced ropiness in beer to *Pediococcus Cerevisiæ*, and considers that the ropiness of bread is probably due to similar origin.

P. Schutzenberger ("Fermentation," 4th Edition, 1886) devotes a chapter to viscous fermentations and quotes observations of Pasteur, who found small globular organisms 0·0012 to 0·0014 mm. in size, which grew at 30° C. in solutions containing sugar.

The products of the organism per 100 grms. of sugar, are stated to be mannite 51·09, gum 45·5, carbon dioxide 6·18.

These observations have been largely used by writers upon breadmaking in explaining the causes of ropiness in bread and the products resulting from it.

Resulting from a comprehensive investigation of 16 samples of ropy bread found in Germany, *J. Vogel* ("Zeits. f. Hygiene und Infektions Krankheiten," **26**, 393) isolated two species of bacteria which he identified as being members of the group of potato bacilli, and which he named *B. Panis Viscosus I.* and *B. Panis Viscosus II.* respectively. *Jackenack* ("Z. Anal. Chem.," **39**, 73) found a similar organism in a black bread which he investigated.

The finding of potato bacilli in bread has also been reported by other workers, among whom, Uffelmann, Emil Laurent, Kratschmer, and Niemilowicz should be mentioned.

So far as I am aware, however, no investigation of the organism to be found in ropy bread, occurring in this country, has hitherto been published, I therefore take the opportunity of recording the following observations:—A brown loaf was taken from a batch of bread which had gone very ropy, portions of the sticky material from the centre of the loaf were removed with a sterile platinum

[illegible] with sterilised water. Portions [illegible] with traces of the resulting [illegible] at 37° C. in the incubator. Growth occurred in 36 hours upon all the media, viz., nutrient gelatin, agar, sterilised bread, and in peptonised wort. A microscopic examination showed all these cultures to consist of a short motile bacillus. By repeated sub-culturing in peptone wort a practically pure culture was obtained. These pure cultures in wort were then used in the following experiments upon the production of ropiness in bread made with a known sound flour.

I. Sound loaves two days' old were taken, and cut into two with a sterilised knife. One half was then infected with three loopsful of a wort culture, at the centre of the crumb, and afterwards placed in a moist chamber at a constant temperature of 28° C; in each case the second half which had not been infected, being placed side by side with the test so as to form a check. The results from four of these tests are given in Table I.,

in [illegible] one loaf of about 400 grms.

Doughs were [illegible] ture, [illegible] two hours, then moulded, proved [illegible] for 40 minutes at an oven temperature of [illegible] A series of seven tests was made, and in each proportion of water increasing from 1 to 5 c.c. was [illegible] from the mixing water required for dough [illegible] replaced by an equivalent volume of a peptone wort culture of the bacillus. The fermentation of these doughs was quite normal, the dough presenting no [illegible] of the effect of bacterial activity when moulded and proved. The resulting bread was light and bulky, with a [illegible] normal odour, flavour, and appearance when it [illegible] oven. These loaves were cut into two with a [illegible] knife, and one half was placed in the incubator at a [illegible]

Table I.—Inoculated Bread.

No.	Loaves kept in moist chamber at constant temperature.		
	½ Loaf inoculated with 3 loopsful of wort culture.	Temperature of incubator.	½ Loaf not inoculated kept as check.
1	Small brown patch in 12 hours, gradually extending until ¼ of crumb had been destroyed in 14 days.	30° C.	Remained perfectly sound during 14 days. Some of mould about 15th day.
2	Ropiness appeared in 14 hours, very gradual increase during 7-day test.	28° C.	Free from ropiness during 7-day test. Mould appeared at 12th day.
3	Crumb completely destroyed in 10 days and reduced to pasty mass.	35° C.	Remained quite sound and free from ropiness.
4	1 c.c. wort culture inoculated. Large central patch in 8 days.	30° C.	Kept in dry air at 15° C. Quite sound and without any sign of rope during test of 8 days.

In each of the tests, ropiness was found to develop in the inoculated portion of the loaf to such an extent in 12 hours, as to be unmistakably recognised. The rapidity with which it spread throughout the mass depended upon the temperature. The higher temperatures (35° C.—40° C.) greatly accelerating it. In no case did the uninfected portion develop ropiness, though the test was continued until moulds (chiefly penicillium) made their appearance.

A number of baking tests were next made, a patent flour being selected for the purpose which had been previously tested and found to yield perfectly sound bread.

Note.—Patent flours are produced entirely from the centre of the endosperm.

The doughs were made with distilled water in a porcelain trough, compressed yeast being used for fermenting.

The proportion of materials used was similar to that

temperature and in moist air, whilst the check [illegible] were kept at room temperature for seven days [illegible] further four days at room temperature (about 15° [illegible] in a moist atmosphere, the object being to ascertain [illegible] effect of low temperature alone as compared [illegible] temperature and moisture.

In Table II. will be found the results obtained [illegible] this series of tests. Photograph I. illustrates [illegible] appearance of test 9. In no case did any of the bread made from these doughs, inoculated with [illegible] of the bacillus, develop ropiness, providing the [illegible] ture at which the loaf was kept did not exceed 15° C. Presence of moisture was without effect at such [illegible] tures. On the other hand, every portion, [illegible] of the quantity of culture added, became [illegible] tures between 25°—30° C. in a moist [illegible] presence of the disease could be detected by [illegible] istic odour accompanying its development, long [illegible]

any obvious changes in the bread had made their appearance. After a variable period the peculiar browning and softening of the crumb made its appearance which is indicative of the advanced stages of the disease.

In order to further test the influence of atmospheric conditions, a sound loaf was taken, cut into two and each half treated with 1 c.c. of a wort culture. One of these sections was kept at 28° C. in the moist chamber, and the other at 16° C. in a dry cupboard, the crumb being kept moist with sterilised water. The portion in the moist chamber became quite ropy in 24 hours, whilst the other half did not show any sign of the disease at the end of 28 days though still quite moist. Fig. II. shows the condition of these two pieces.

Elevated temperature would thus appear to be absolutely necessary to the development of ropiness in bread, even when the bacillus is present in large numbers, moisture alone when temperature is low, being incapable of causing its appearance.

In the course of experimenting with cultures in various media it was found that acidity either checked, or altogether stopped the growth of the organism, according to the degree of acidity present.

Thus flasks of peptone wort containing 0·1 per cent. acetic acid were inoculated with three loopsful of a young agar culture, and incubated at 28° C. Controls with peptone wort containing no acetic acid being run at the same time. In the acid flasks no growth was obtained, but the neutral flask developed a good culture. In a further experiment 0·06 per cent. acetic acid yielded similar results. When lactic acid was substituted for acetic acid it was found that alcoholic fermentation occurred in one of the flasks, but the rope bacillus could not be detected either by the growth in the medium or by microscopic examination, whilst in the other flasks results similar to those produced by acetic acid were obtained.

It appeared to be probable, therefore, that if slight acidity of the medium prevented the growth of the bacillus in liquid cultures, it should be possible to entirely suppress the disease in breads if the doughs were made slightly acid. A series of loaves was accordingly made, the doughs of which were rendered slightly acid with varying proportions of acetic and lactic acids. A relatively large amount of wort culture was added to each dough. The quality of acid used in these doughs has been calculated into pounds of real acid per sack of flour, as this is most convenient for baking purposes. The quantities used, with results obtained, will be found in Table III.

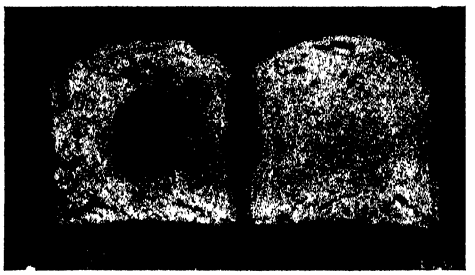
Photograph III. shows the results obtained from a parallel experiment. Both these loaves were made from the same flour, yeast, &c., and each dough was mixed with 5 c.c. of the same wort culture of the bacillus. To one of the doughs was then added 0·3 of acetic acid, whilst the second dough was left in the natural condition. Fermentation and baking were precisely similar for both loaves. After baking they were both kept in the moist chamber at 27° C. The loaf marked, A, which contained no added acid, became distinctly ropy in 24 hours, the disease progressing rapidly during the remainder of the test. Loaf, B, which contained acid, was perfectly sound at the end of five days when the photograph was taken.

These acid loaves were generally of good bulk and sweet and, with exception of experiment 13, they did not betray any sign of acidity to the taste or smell. On account of the rapidity with which the acids used affect the gluten, it was always necessary to see that the fermentation was not prolonged unduly, but, it was never found to be difficult to control this action, so long as the acid did not exceed about 1 lb. per sack of flour.

In experiment 13, mentioned above, the acid did break down the elasticity of the gluten and the resulting bread was heavy, close and damp, a condition presumably favourable to the bacillus, but it will be noted that the disease did not manifest itself.

A consideration of all the results obtained leads to the conclusion that the addition of a small quantity of acetic acid to the dough will effectually prevent the appearance of ropiness in the resulting bread during much longer period than bread is usually kept. The minimum quantity of acid appears to be about 0·3 lbs. per sack of flour, whilst a maximum of 0·7 lbs. should not be exceeded on account of its softening action upon the gluten.

When lactic acid is employed as a preventive, the minimum quantity is greater; below 0·6 lbs. per sack its action is somewhat uncertain. The greater softening action of this acid upon gluten must not be lost sight of when considering the quantity to use.



The resistance of the bacillus, or its spores, to heat is very great indeed, as was shown by the following experiments:—A peptone wort culture was immersed in a

boiling water-bath for 30 minutes on three successive days. Streak cultures on agar were made after each boiling and incubated at 28° C. All the cultures yielded vigorous growths, and bread tubes inoculated from the thrice-boiled wort became typically ropy. Microscopic examination of the cultures also revealed the same organism as was originally isolated.

Two doughs were next inoculated with portions of this boiled culture, fermented and baked as before. The results will be found in Table IV.

or flour store; dirt accumulating in false bottoms and crevices of troughs, &c., have each in turn been advanced as the cause of the sudden appearance of this disease, and elaborate methods for purifying and sterilising all apparatus have been devised, as the best means of eradicating it when it has once revealed its presence.

Such methods have frequently proved totally inadequate to accomplish the desired end, even when carried to the extent of putting in a complete new set of utensils and reconstructing the bakehouse.

Table IV.—Boiled Culture.

No.	Flour used	Amount of boiled wort culture added in the dough	½ Loaf kept in moist chamber at 28° C.				½ Loaf kept at 16° C. in dry cupboard for 7 days.
			12 hours.	24 hours	48 hours.	72 hours.	
28	Patent grade	c.c. 0·5	Ropy smell	Crumb dark in colour	Damp and quite ropy	Whole crumb sticky and brown coloured	Quite sound
29	„	1·0	„	Ropy smell	Crumb darkened in colour	Centre quite sticky and brown coloured	Quite sound

The noteworthy feature of these tests was that, after three boilings of 30 minutes and one baking of 40 minutes, the organism was not only alive but extremely active, the disease appearing somewhat earlier and spreading with greater rapidity. This test also shows how hopeless a task the baker is recommended to undertake, when he is told to give bread liable to rope an extra long baking, in order to prevent the disease appearing.

The morphological and cultural characteristics of the organism isolated from the bread and from the various media, are as follows:—A short rod with rounded ends, frequently united in pairs, seldom in chains of more than three. It readily forms ovoid spores which almost entirely fill the cell. In length, it is from 1· 1·25 μ; in breadth, 0·75 μ.

The micro-photo of the organism, Fig. IV., is taken from one of the loaves inoculated with a peptone wort culture of the bacillus, which had been started from flour.

In hanging drop.—Sluggishly motile, organism surrounded by a translucent capsule.

Staining.—Good by Gram, Carbol Fuchsin, Methylene Blue. Spore staining very difficult, usually only successful by Müller's method. Grows best at temperatures between 25°—40° C., stagnates at 15° C.

Agar.—Smeary white growth, brownish on looking through the medium, edges of growth irregular. Whitish film on water of condensation.

Gelatin.—Shining, barely visible, filmy growth, very slowly liquefying the medium.

Wort gelatin.—White crinkled growth, slowly liquefying medium.

Peptonised wort.—Rapid growth, rendering liquid turbid, and forming a slimy gelatinous film on the sides of flask and surface of liquid. The wort acquires a faintly urinous odour.

Sterilised bread.—Becomes brownish, as if saturated with syrup, and is gradually converted into a moist viscous mass, emitting a strong valerian-like odour.

Milk is coagulated, clot partially redissolving upon long action.

Potato.—Quickly becomes covered with a white crinkling growth which turns brown with age. A peculiar burnt, musty odour is evolved.

The foregoing characteristics leave little doubt as to the identity of the organism with *bacillus mesentericus fuscus* (Flügge. Lehmann and Neumann's "Atlas of Bacteriology," page 326, Plate 43).

The bacillus is a frequent inhabitant of soil, vegetables, &c., and doubtless also of the cereals.

Perhaps the most important question, from the practical baker's point of view, is, how and when the bacillus gains access to his doughs. It would appear from a perusal of the methods generally advocated for the prevention or cure of rope, that the bakers are to be held almost entirely to blame for its appearance in the bakery.

Dampness and insufficient ventilation of the bakehouse

It has been noticed, however, in more than one case that a complete change of flour was accompanied by a disappearance of the disease equally as sudden as its onset. The suggestion that the flour was the real medium conveying the bacillus, or its spores, has been vigorously combatted by millers, but positive and conclusive evidence, either for or against this view, does not appear to have been available hitherto.

During the autumn of 1905, a large firm of bakers in the North had the misfortune to find their bread suddenly attacked by this disease. They dealt promptly with the matter by discarding all flour in stock and replacing it with fresh flour from a totally different source. As a result, the trouble immediately disappeared. A series of careful baking tests of each of the brands of flour forming the old stock was then undertaken, with the result that all but one brand were found to be perfectly sound. Every blended flour into which this particular brand entered was also found to yield bread which became ropy. The evidence was conclusive that this flour carried the bacillus and had been the means of introducing rope into the bakery. At my request the firm kindly furnished me with some of this flour for investigation. It was an ordinary bakers' grade, somewhat soft and of low water absorbing capacity. It contained 10·45 per cent. dry gluten grey and rather short in texture, the soluble matter was 4·46 per cent. and the reaction was slightly acid (0·132 acetic acid per 100 grms).

A series of cultures upon various media was started, using a very thin paste of the flour made by thoroughly triturating 1 grm. of flour with 100 c.c. sterile distilled water, the medium being inoculated with 1 loopful of the well stirred emulsion. Upon cultivation, growths were obtained identical with those previously isolated from ropy bread.

Sterilised bread was rapidly turned completely ropy by one loopful of the flour mixture; check tubes ran concurrently remaining unchanged.

From each of these cultures stained preparations were made which upon microscopic examination revealed short sporing bacillus, similar to the *B. Mesentericus* previously isolated from bread. Fresh subcultures in peptone wort were started and baking tests afterwards made with them using the patent flour employed previously.

The whole series amounting to 10 loaves became ropy within 48 hours.

A set of loaves was made from the suspected flour alone, without addition of any culture. On testing these in a similar manner to those recorded in Table II., it was found that all the half loaves kept at 26°—30° C. in moist air became thoroughly ropy, whilst the check portions maintained at low temperatures 14°—16° C. remained sound during testing periods of 14 days.

A repetition of the acid experiments yielded results in conformity with those in Table III. Portions of the

suspected flour made into bread with addition of acid did not go ropy during the usual testing period (see Table III., Nos. 18, 19, 24, 25, 26).

The above series of tests having shown that the bacillus was, undoubtedly, present in this sample of flour, an attempt was made to see whether yeast was in any way essential to the development of the organism in bread. Accordingly some loaves were made without yeast, a commercial baking powder in the proportion of 10 grms. in 280 grms. flour being substituted as the aërating agent.

In all five tests were made, and a reference to Table V., Photo V., will show that ropiness appeared in the usual time in each case, demonstrating that the development of the disease is independent of the presence of yeast.

at 28° C. In the bakery, the prover would be found equally efficient, or the neighbourhood of the oven, provided suitable means be taken to protect the tubes from dust and accident.

At the expiration of 24 hours the tubes should be examined, both for appearance of the bread and also by smell for indications of ropiness. If *B. Mesentericus* be present, the whole of the tubes containing the flour solution will generally exhibit positive indications of ropiness, the check tubes remaining unchanged. The experiment should be continued a further period of 24 hours, with examinations at intervals, for confirmation, by noting the rate of increase of the disease, which is usually rapid.

If a portion only of the inoculated tubes shows signs of

Table V.—Baking Powder.

No.	Brand of flour used for making dough	No. of c.c. peptone wort culture of bacillus added	½ Loaf kept in moist chamber	Temp. °C.	½ Loaf kept at room temperature.	Temp. °C.
30	Suspected flour entirely	None	Ropy in 24 hours	27	--	--
31	Patent grade	2 c.c.	Ropy in 36 hours but not very pronounced	30	Quite sound and apparently sweet at expiration of 4 days, kept dry	16
32	" "	5 c.c.	Ropy in 36 hours, large central patch in 4 days	28	Surface kept moist by distilled water Quite sound for 96 hours	18
33	25 per cent suspected flour 75 per cent patents	None	Apparently sound for 30 hours Slight ropy odour in 48 hours Crumb coloured pink in 60 hours	28	Perfectly sound at end of 48 hours	18
34	Patent grade	5 c.c.	Ropy in 30 hours, entire crumb discoloured in 72 hours	26	Sound at end of 96 hours	16

In this case the evidence establishes beyond doubt the existence of the bacillus in the flour, but there is reason for the view that, in modern practice, flour is the only material responsible for the appearance of this disease.

It must be mentioned that, in the past, the introduction of rope bacillus may occasionally have been due to the use of potato ferments. The use of potatoes is now almost obsolete, certainly among progressive bakers, and the fact that *B. Mesentericus* is known to commonly exist upon potatoes should furnish a strong additional reason for the abandonment of their use in bread-making.

The loss and anxiety entailed when goods became attacked by rope, renders a reliable and rapid test for the presence of *B. Mesentericus* very desirable.

I find that the following test satisfies all the requirements of the practical baker, it is very delicate, a positive result being readily obtained from 0·02 grms. of a ropy flour. On the other hand, there is no fear that genuinely sound flours will fail to pass the test, because they do not yield appearances which resemble ropiness in the time proposed as a limit. Ten large test tubes (6 in. by 1 in.) are thoroughly boiled in water for one hour, washed and drained. When drained place in the oven and bake at 232° C. (450° F.) for three hours to completely sterilise them. Cool and then place into each tube a finger of bread 3 in. by ½ in. by ½ in., cut from the centre of the same 2-day old loaf. (The average weight of each piece is 5 grms.) Moisten each piece with 5 c.c. of recently boiled distilled water, then plug all tubes with cotton wool and sterilise by immersion in boiling water for one hour on three successive days. These tubes are conveniently prepared in batches a few days previous to being required.

In order to test a flour, 2 grms. are taken from sample and well mixed with 100 c.c. of distilled water. The beaker containing the mixture is placed in a boiling water bath for 30 minutes, in order to destroy all organisms except spore formers like *B. Mesentericus*, &c.

To the series of 10 prepared tubes add successively 1 to 7 c.c. of the boiled flour mixture, leaving the three remaining tubes to serve as checks. Number the tubes in rotation. The precaution of having three check tubes is necessary in view of the known vitality of the mesentericus group, and no test should be considered satisfactory unless all three check tubes remain quite sound.

Immediately the tubes have been inoculated, the wool plugs are replaced, and the 10 tubes put into an incubator

ropiness, it is better to repeat the experiment before condemning the flour; when the bacillus is present in dangerous number, indications can usually be found in every tube inoculated, though frequently not yielding a growth proportional to the amount of flour solution added.

If the tubes reveal no indication of ropiness in 48 hours, the flour may be passed as sound. It is not practicable to prolong the experiment beyond 48 hours on account of the development of other organisms, moulds, &c. When *B. Mesentericus* is present, its existence is always manifested within 36 hours of starting the test.

Summary.

Ropiness in bread is produced by varieties of *Bacillus Mesentericus* (Flugge). The bacillus is introduced into the dough through the flour, in which material it sometimes occurs in large numbers, possibly coming from the bran coats. Breads containing bran and straight grade white flours are most prone to develop ropiness.

The bacillus is a prolific spore former, the spores being capable of resisting high temperatures for prolonged periods.

Once present in the dough, development of the bacillus, after bread has been made, depends partly upon the reaction of the bread and partly upon atmospheric conditions.

Bread is only faintly acid in reaction and always insufficiently so to naturally prevent the development and spread of ropiness, but if the acidity be increased by addition of small quantities of acetic acid to the dough, development can be prevented.

Low temperature and dryness of the bread store tend to suppress development, but the maximum temperature of 18° C. (65° F.) cannot be exceeded without great risk.

When a batch of bread is found to be ropy, all flour in stock should be at once tested, so as to locate the infected stock and in the meantime fresh supplies of flour from a different source should be laid in.

When the infected batch of flour has been discovered, it should be isolated, so that it can be worked up under those conditions which are most unfavourable to the development of the bacillus, *i.e.*, the doughs being made slightly acid and the bread being quickly cooled and kept at low temperature during storage. Such flour might advantageously be kept until the colder months, when the prospects of development are at a minimum.

During the summer months the danger of purchasing ropy flour may be entirely obviated by the application of the bread tube test to a sample of the flour before buying.

Discussion.

The Chairman said he had been much interested in a suggestion of the author as to the use of acid in preventing this contamination of flour, for they would all agree that the evil resided substantially in the flour itself, and not to any appreciable extent in outside substances which were likely to be used. The author recommended the employment of lactic and acetic acids as deterrents, but he asked if the proportion in which he suggested their use would not have a deleterious effect on the bread produced. The sample exhibited at the close of the paper smelt very strongly of acetic acid, which would certainly be objectionable. He did not know whether he had found that with lactic acid he could prepare a bread with no injurious properties. He would also call attention to a matter which had been in the minds of many, namely, the employment of nitrogen peroxide with a view to producing a bleaching effect on flour. That had been quite recently the subject of litigation, and it had been stated by a number of experienced millers that the use of nitrogen peroxide in traces, in addition to the effect of bleaching, brought about an improvement in the flour itself. Now, if acidity were requisite for the prevention of the work of this bacillus, it would be interesting to know whether the same effect would be produced by employing traces of the much more potent nitrogen peroxide. He noticed that the author said that when he replaced the yeast by baking powder he did not get such objectionable results as regarded ropiness, and it would be of interest to know whether that was due to any particular ingredient of the baking powder, or whether he had examined the yeast employed for bacterial impurities. The author further told them that when he used bran in the flour there was more likelihood of this "rope" being developed than when it was not present, and he asked whether, in his opinion, there was any constituent in the bran itself which encouraged the growth; otherwise it was rather difficult to understand how the mere presence of the bran, unless associated with bacteria, would have this effect. It appeared that the "rope" flour and bread had been submitted to a temperature at which the spores were not destroyed, but he would like to ask if the author had examined the dough, and if he could tell them at what stage the spore development commenced and was at its maximum, and what was the condition of the dough with regard to the appearance of the *B. Mesentericus fuscus* in it. In what respect did this *B. Mesentericus fuscus* differ from the *B. Mesentericus vulgatus* described by Loffler, which produced similar ropiness in milk? That was the so-called potato bacillus, and he asked whether these were varieties of the same species or essentially different, or whether they were both common to the so-called peptone bacilli.

Mr. W. Jago asked the author whether he had tried either of the odourless mineral acids, such as sulphuric or phosphoric acid instead of acetic acid, because, with regard to the diseases of bread, the baker placed that of sour bread as the first and foremost, and he was afraid that if it was suggested to the average baker that in order to get rid of ropiness he should get his bread charged with acetic acid, he would be inclined to regard the remedy as worse than the disease. He noticed the remark that ordinary bread was only very faintly acid, and, as a matter of fact, it was but faintly acid to all ordinary tests; but notwithstanding that, a number of samples of sour bread contained acetic and butyric acid in quite sufficient quantity to render them objectionable in flavour and character. One point which struck him was the references to the baker's ordinary remedy for ropiness, namely, baking his bread as thoroughly as possible. This, as the author had indicated, meant drier bread, and there was less chance of the development of the ropy organism. The breads which were going to become ropy were usually those in which there was the presence of dextrinous, or gummy bodies—not merely dextrin, but also bodies of the soluble proteid type. It was probably known to many that, in order to overcome the dryness of breads produced by modern methods, in which the bran and everything associated with it was as far as possible removed, and potatoes were no longer used, it had become customary to boil starch in some form and add the gelatinised starch to the bread in the making. Now breads containing this gelatinised starch became ropy much more readily than those from which such starch was absent. This only pointed to the fact that certain forms of bread, and bread possessing certain characteristics, were better media of growth than others. He congratulated the author on the simplicity of the method suggested for determining whether any particular flour was the source of ropiness. Ropiness he regarded as being introduced by the flour, because of certain organisms, germs, and spores residing on the outer coating of the bran. Having once come into the flour, and through the flour into the bread, there was no doubt of the fact that the greatest possible cleanliness in troughs and in utensils was a means, if not of prevention certainly of cure. But having once got a growth of this kind into a bakery the re-infection would be continual. One of the methods of re-infection that had occurred in his experience had been in the bread cooling rooms themselves, where by successive elimination of the various defective materials, the yeast, the potatoes, the flour, and gradual working at each until the original source was removed, there yet remained the room in which the bread was stored, the loaves remaining from one batch apparently had affected the successive batches, and after everything else had been got rid of, this source of infection remained. Again the question of thorough sterilisation by every possible means of utensils, the rooms, the delivery vans and even the clothing worn by the men delivering the bread, was of importance.

Mr. E. Grant Hooper said that he had no experience of any such extreme degree of ropiness as was represented by the bread placed before them that evening. It must be apparent to all, on looking at the samples, that it was in the centre of the bread, the moister part, that this development had occurred, whilst the outer or drier portion presented no abnormal feature. This made him inclined to suggest that the baking was in many cases at fault where the evil appeared, whether it was of an extreme character, or a much less pronounced case where the bread was merely sour. No doubt this infection would spread where a decided development of the ropy organisms occurred in a bakery; but he would like to ask the author whether he had any experience of the general bacteriological examination of flours. He was of opinion that where flour was badly treated, where it was allowed to get or to remain damp, that sort of development was likely to occur, and he would suggest that the particular organism and others akin to it were much more widely spread than was commonly supposed. If flour were kept dry the development of such organisms to any serious extent appeared to be infrequent, but, in such samples as had come before him, he had always observed that it was ill-baked, moist bread of which complaint was made. Such bread, if kept for, say, a fortnight, would almost always become mouldy, indicating that it was more damp than ordinary, good sound bread. He agreed with the Chairman in thinking that the addition of acetic acid would probably prove highly objectionable to consumers, for he certainly thought that the samples passed round were much too acid to be accepted as satisfactory bread.

Mr. A. E. Humphries asked whether the abnormal proportion of yeast used had anything to do with the extreme cases of ropiness which were produced. He found that an addition of 0·25 per cent. of lactic acid absolutely spoilt the bread for commercial purposes. Frichot, who claimed to hold the master patent for bleaching flour, had stated that his object was not to make the flour whiter, but to sterilise it. The author had told them indirectly that the bacillus survived the oven, and he traced it back to the flour. As a miller he was anxious to know how the flour picked it up, and where it came

[illegible] Was it claimed that the trouble arose from the flour always, or only that it did so in the case particularly referred to in the paper?

Mr. Lawrence Briant said when bread became ropy, which was a somewhat rare occurrence, it occurred generally in breads which were peculiarly moist. When materials were used in baking, such as malt extract, which increased the moisture, and partially dextrinised the starch, the resulting bread was known to be more prone to become ropy than in other cases, and it therefore seemed as though the percentage of moisture in the bread had a good deal to do, not with the presence, but with the activity of the particular bacillus. It was interesting to know that this bacillus was in the flour, and was not due to dirt or carelessness in the management of the bakery, although it was easy to understand that carelessness would perpetuate its growth. Some years ago Mr. Jago and himself, independently working on the causes of sourness in bread, came to the conclusion that it was due in most cases to bacteria present in the flour, and not, as was previously imagined, to contamination in the bakery, although no doubt that was responsible for a good deal of sour bread. It also seemed clear that ropiness occurred, or was likely to occur, in an underbaked loaf more than in one thoroughly baked. The temperature in the interior of the loaf was not 400° F., for a number of observations of temperature were made by Mr. Jago, and some by himself years ago, and it was then observed that the temperature seldom rose above 205°; 98°—203° F. was the usual temperature in the interior. Possibly, had the temperature been higher, the bacteria, if not destroyed, would at any rate have become less active. With regard to the addition of acid to dough, that would surely be inadmissible from many points of view. Amongst others, when bread was acid it became peculiarly chaffy in character, a condition much objected to by the public, and for that reason alone the use of acid should be condemned.

Mr. Julian L. Baker referred to the treatment of flours by bleaching agents, one of which was nitrogen peroxide. It seemed to him that such treatment might seriously modify certain conditions in bread making, because the natural flour contained active diastase. That diastase would, of course, act on the wheat starch during the making of the dough, during its fermentation, and in a measure during the baking. It was probable that quite a different set of carbohydrate constituents would be found in the ultimate loaf if the diastase were destroyed.

Dr. S. Rideal said in regard to the acid treatment, he thought both acetic acid and lactic acid were unsuitable for preventing ropiness. The experiment with baking powder suggested that possibly alum or tartaric acid were preventatives, and he would suggest that the author try bisulphate of soda, which he had found an excellent germicide, in the place of free acids in the sterilisation of water.

Dr. E. Frankland Armstrong said the author had identified this bacillus with the *B. Mesentericus*, but he had omitted to say whether he had tried a pure culture of *B. Mesentericus* in bread to ascertain whether similar ropiness was produced. It seemed to him that was a point of considerable interest. He did not quite gather whether, in sterilising flour, the infusion which Mr. Watkins told them was swarming with this bacillus, he sterilised for once only, or say for 40 minutes, on a particular day, keeping the infusion at a temperature of about 95° for another day, and then again sterilised it in the same way as one was accustomed to sterilise water. If that particular bacillus were capable of forming spores resistant to heat under such very drastic conditions, it would be a very remarkable one. Interesting and convincing as the experiments were, it did seem to him that the author had at times worked under unusual conditions in taking such a large quantity of yeast—5 lb. to the sack, as had been pointed out, was altogether abnormal. A considerable quantity of the nitrogenous substances derived from the yeast, many of them not only injurious in themselves, but containing food substances very favourable for the development of bacteria, were thus introduced into the bread. Yeast, as it came into the hands of the baker, was of course full of bacterial impurities of all kinds. It was only owing to its excessive activity, and the fact that the primary fermentation came to an end before these subsidiary disease germs were able to develop, that the immunity of the baker from much more serious evils than ropiness was to be attributed. He should also like to ask if the author had tried the effect of minute traces of alkalinity on this particular bacillus.

Mr. A. C. Chapman asked if the author had made any experiments to ascertain whether it was possible for the bacillus in question to communicate ropiness to other materials than bread, such as beer, wine, wort, milk, &c., all of which were well known at times to exhibit the phenomenon of ropiness. He had been particularly struck with the singularly successful manner in which the author had always been able to reproduce ropiness with the organism he had isolated. It was the experience of those who had investigated this subject in reference to other substances that ropiness was a very capricious phenomenon. An organism isolated from a ropy liquid was sometimes found to induce ropiness in other liquids quite readily, whereas at other times no such result could be obtained. He (Mr. Chapman) had often observed this in the course of his own work.

Dr. P. Schidrowitz said ropiness occurred in many liquids like beer and wine, and a number of organisms had been isolated, but they always appeared to be different. There was the *B. Gummosus* of Happ, the bacillus found by Laborde, and the bacillus described by Gayon and Dubourg, which all produced ropiness and the concomitants of ropiness, such as mannitol, and he should like to know if, in his experiments, mannitol was isolated?

Mr. Watkins said perhaps he had not been sufficiently explicit as to the use of baking powder in the bread, because several speakers had taken it that he then got better results; as a matter of fact, reference to the tables would show that he got equally bad results, and it struck him that was proof that the yeast was not in fault. Reference had been made to the claim that bleaching the flour also had the effect of sterilising it. His results did not support the theory, as one of the flours that yielded ropy bread had been bleached by the well-known process referred to by the Chairman, in which nitrogen peroxide was used. The question had been asked how the bacillus got into the flour? He should be inclined to say it got in on the bran coating, and was derived directly from the land upon which the wheat was grown, because, as he pointed out, the breads most liable to it were those which contained either bran, or were low-grade white flours containing much bran and offal. Further, the disease appeared to be much more common in Germany, where black bread was largely used. The fact that so much white bread was used here was probably the explanation why ropiness was uncommon. Under modern conditions of breadmaking it was probable that flour was the sole cause of ropiness. The use of mineral acids had been advocated, but he hardly thought these could be justified as substitutes for organic acids in an article of diet. The same objection must also apply to alum, against the use of which many reasons could be urged. He was not sure that the use of acetic acid was so deleterious as some of the speakers seemed to think. Many people took far more acetic acid than he advocated in the form of vinegar. He had calculated that if the minimum quantity of 0·3 lb. per sack were used, it only increased the percentage of acid in the bread by 0·0708 per cent. With regard to the odour of the loaves exhibited, he might say that when they left the oven they did not smell markedly acid to him. The odour which they now possessed was a close odour, and was the natural effect of being kept from five to seven days in a closed incubator at a high temperature and in a moist atmosphere. A good, sweet loaf could be obtained with 0·27 lb. of acid per sack.

Some bread had been mentioned, and it must be admitted that appreciable quantities of acetic and lactic acids were found in such bread, but it should be pointed out, that, so far as the evidence went, the tasting of the

bread was not always proportional to its "sourness," so that those terms were not synonymous. In his experiments, pure acids had been used, and it was not found that the bread, even when it contained as much as 1 lb. of acid per sack of flour was "sour," though it certainly possessed the odour of acetic acid.

Bread, containing gelatinised starch and other hydroscopic substance, undoubtedly furnished a better culture medium to the bacillus which, in his opinion, was largely due to the superior moisture-retaining properties of such breads.

It was difficult to understand how the loaves from one batch could affect succeeding batches by simple external contact in the cooling room. In every case coming within the author's knowledge, ropiness developed first at the centre of the loaf and only after a long time did it extend to the crust. Even then the crust was never penetrated. It would, therefore, appear that the outer portions of the loaf were sterilised, but that towards the centre the spores survived the baking process, and afterwards developed, if conditions proved suitable.

Dryness of the flour, whilst undoubtedly an essential in making a good keeping flour, could hardly help much in the suppression of rope, for the reason just stated, as it was the spores which had to be feared rather than the bacilli. Such drying as would be accomplished by the miller would probably have the effect of causing spore formation.

It was, perhaps, hardly necessary to justify the use of 5 lb. of yeast per sack, in view of the fact that ropy flour made with baking powder produced ropy bread under suitable climatic conditions. Briefly, the reason was that by this means a quick fermentation could be attained, thus preventing any undue development of bacteria in the dough stage. When the small amounts of yeast mentioned by some speakers were used it must be remembered that the fermentations were much more prolonged than was necessary with large quantities of yeast, consequently the danger of bacterial development was greater. Long fermentations were admittedly favourable to bacterial activity, whilst short, vigorous fermentations were distinctly inimical to bacterial growth.

New England Section.

Meeting held at Boston, on Friday, March 2nd, 1905.

VICE CHAIRMAN IN THE CHAIR.

ANTIMONY COMPOUNDS AS FIXING AGENTS FOR TANNIC ACID.

BY W. S. WILLIAMS.

Of the different bodies available as fixing agents for tannic acid on the vegetable fibres, the antimony compounds are by far the most important. The choice of the best salt of antimony to use for a particular class of work is a more difficult matter, and depends on several different factors. The most suitable form for yarn may not answer as well for piece goods, the best fixing agent for cloth mordanted with tannic acid by steeping, is not necessarily as well adapted to precipitate the tannic acid applied by padding, or again, the antimony compound giving the most satisfactory results in piece dyeing may fail to answer as a fixing agent for printed goods.

A perusal of the literature of the subject will leave one even more at sea. All kinds of impossible claims are made by the advocates of the various compounds, and these improbable statements are so interwoven with the facts of the case, that it becomes extremely difficult to sift the evidence. Most of the experiments are made on yarn mordanted with tannin by steeping, and the results taken as conclusive for all forms of fibre and methods of operation.

The statement that a compound containing only 15 per cent. of antimony oxide will replace, weight for weight, one containing 40 per cent. or more is improbable, to say the least, and is not borne out either by theory or practice. The weaker compound may, however, possess other properties which will for certain work more than counterbalance the difference in strength. In many cases where tests are given, one of the antimony compounds is present in large excess, so that the weaker compound, taken in equal quantity, is still able to fix all the tannic acid on the fibre. The only test at all conclusive is one which takes into account both the antimony combined with the tannic acid in the fibre and that left in the bath, and still capable of reacting with more tannic acid. The experiments, to which I call your attention, are chosen from a long series undertaken to determine the relative values of the different antimony compounds under specific conditions. That is, the fixing in a continuous machine of cotton piece goods which had been padded with tannin liquor and dried. The factors considered are cost and resulting shade.

The first attempts were made by taking swatches from the cloth from time to time and samples from the bath for analysis. The results were hardly satisfactory. Differences were found in the weight of the pieces of cloth, and consequently in the amount of tannic acid taken up. The variation in depth of shade, due to this cause, was found in most cases to be greater than that produced by the different conditions of the antimony bath. The analysis of the weak antimony solution was difficult and tedious, and offered no method of separating the available oxide of antimony from that already combined with tannin, but left in the bath. To supplement these, I finally resorted to laboratory trials which I have found to give the most comprehensive comparison of the relative values. The method consists of the progressive exhaustion of an antimony bath by the successive introduction of patches of tannin prepared cloth, and the subsequent dyeing of all the patches with an excess of basic dyestuff. The mode of operation may be briefly outlined as follows:

Separate baths are prepared of the various antimony compounds in 750 c.c. water, and so calculated as to contain the same quantities of antimony. The bath is maintained at 49° C., while introducing successive 10 grm. patches of mordanted cloth. Each swatch is worked for 10 minutes, wrung out, and another lent introduced. As soon as removed from the fixing bath, each patch is rinsed in cold water. After all the patches had been fixed (four or five in each bath are all that are required), they are well washed and dyed together in a bath containing an excess of Methylene Blue or some other basic dyestuff. For cloth padded with a liquor containing 2 oz. of dry tannin per gallon, the bath should contain 0·10 - 0·12 grm. of 75 per cent. antimony fluoride, and the other compounds in proportion. For comparison, a patch of the same cloth is worked $\frac{1}{10}$ minutes in distilled water, rinsed, and dyed with the others.

The first table gives the more common antimony compounds with their relative strength. The first eight given are the compounds used for the trials shown in the second table. The percentages given were determined volumetrically with iodine solution. With the exception of the lactates, the titration may be performed without starch solution, the iodine serving as its own indicator. The results obtained by this method, although not as strictly accurate as those determined gravimetrically with hydrogen sulphide, have been found correct enough for all industrial purposes.

The second table gives the compounds used for a characteristic trial and the results obtained. The results have been proved by repeated trials with the same compounds. The amount of each compound and the relative cost per unit of antimony oxide is figured with the 75 per cent. salt as a standard. These cost values will, of course, vary from time to time, and will differ according to locality.

It will be seen that the first patch in each bath is completely fixed, the patches from the Frochch's "patent antimony salts," the "antimonine," and the lactates being slightly brighter than the others. The second patches from these three baths show a full shade, while the swatches from other compounds which do not dissociate as readily

Relative strength of Antimony Compounds.

are dyed somewhat lighter. In the third set, the baths of these same three compounds are found to be practically exhausted, while the others, which have given up their antimony more slowly still, have enough to fix about one half the tannin present. The fourth set of patches shows all the baths exhausted. None of the baths gave any precipitate with hydrogen sulphide, showing that all the antimony had united with the tannin, even in the case of the compounds most difficult to dissociate.

It will be seen that the claim for the lactates of easy dissociation and complete exhaustion of the antimony is maintained. On the other hand, the remaining compounds, although acting more slowly, have likewise given up all their antimony.

From the trials we are justified in drawing the following conclusions for this class of work:—

With the antimony compounds tested, the fixing power is in proportion to the amount of oxide of antimony they contain.

"Antimonine" and the lactates are the compounds most easily dissociated, and, in this respect, are nearly equalled by the double salt of antimony fluoride and antimony oxalate. Tartar emetic and the corresponding sodium salt give up their antimony most slowly. In practice, for continuous baths, the slightly brighter shade obtained with the lactic compounds is not usually advantage enough to overcome their much higher cost when compared with the fluoride.

These laboratory trials and later experiments carried out in practice do not show any deleterious effects due to liberated acid even from the fluorides. In the latter case I have always used a small quantity of soda, but cannot find that this addition has any influence on the ultimate fixing value of the salt. These results do not agree with those of other writers, notably the experiments described by During (Färber-Zeitung, 1900, page 319). I attribute this discrepancy to difference in strength of antimony solutions, to the time allowed for action (Düring allows the samples to remain in the bath one hour at 60° C.), and, in some cases, to the fact that the mordanted fibre has not been dried before introducing into the fixing bath as in my work.

To further test this action of the acid liberated from the fluorides, the following trials were made, combining practical running and the successive exhaustion test: 30,000 yards of a cloth 10·79 yards to the pound were padded in a liquor containing 4 oz. tannin per gallon, dried and fixed in a continuous machine. The box containing the antimony solution was filled at the beginning of the run with a fresh bath of the usual amount of 75 per cent. antimony fluoride and soda, and maintained throughout the day at the same volume by a continuous stream of fresh solution of the original strength. Nothing was removed from the bath during the run of eight hours except what was carried away by the cloth itself. It will be seen that every possible opportunity was offered for the acid to collect. Samples were taken from the bath at the beginning of the run and every two hours during the day. The original sample was then reduced so as to contain 0·12 grm. of antimony oxide per litre, and all the other samples were reduced in the same volumetric proportion without determining the antimony they contained. The successive exhaustion tests were then made in 750 c.c. of these reduced baths according to the method already described. These results showed no appreciable difference in the fixing value of the baths or the brightness of the shade produced. The last baths were slightly stronger than those at the commencement of the run, but this would be due to the fact that more antimony was added during the day than was used up in fixing the tannin.

From these results it would seem that the action of the liberated acids in stripping the tannin from the fibre and in retarding the action between antimony compounds and tannic acid have been greatly exaggerated. In the case of very light, bright shades, or in the presence of a large excess of acid antimony compounds, this factor might become appreciable, but in the ordinary run of practical work the danger is negligible.

The final test in all cases, however, must be a practical one. Only by such a trial is it possible to determine if an antimony compound will produce the desired results under the conditions existing in the works.

Discussion.

Mr. A. A. Claflin said that the correctness of Mr. Williams' conclusions might be somewhat questioned. The object of printing or dyeing a cotton fabric was to produce a colour, and, in the case of the basic dyestuffs, three factors enter into this colour: tannic acid, antimony compound and dyestuff. Economy could only be considered in one of these factors in relation to its effect on the other two. For example, the cheapest source of tannic acid was mangrove extract, but this could not be used in calico printing because it possessed a colour of its own which would absolutely prevent the production of suitable shades, hence recourse was had to nearly pure tannic acids costing eight times as much. In the case of antimony compounds, it was very easy to show that the fluoride containing 73 per cent. was cheaper than the lactate as a source of antimony. The whole question then was whether, with the fluoride, the final colour was obtained more cheaply and better than with the lactate. The author admitted that the shade produced by the lactate was superior to that produced by the fluoride. That superiority of shade was due, as was pointed out by During, to the fact that the lactic acid had much less solvent effect on the fixed colour than had the hydrofluoric acid. His criticism on the author's work was, that his experiments were not carried on under conditions suitable for determining that loss. It was well known in testing dyestuffs that unless comparative trials were made with very light shades, large differences were imperceptible, because the excess of colour obscured the comparison. The dyestuff was always the most expensive factor in the final colour, and, in the experience of the speaker, the saving of the dyestuff effected by using a lactate instead of a fluoride would more than repay an excess of cost of the lactate. In some recent experiments in a large print works it was found possible to reduce the amount of Methylene Blue in the colour paste 20 per cent., when using antimony lactate, and to still obtain as full a shade as with the larger percentage of dyestuff, using antimony fluoride for fixing.

The author spoke of the addition of soda; chalk was also frequently added to the fixing bath to neutralise the acid, both of these compounds precipitating antimony oxide, and, while freshly precipitated oxide of antimony possessed a certain amount of mordanting power, much valuable oxide was lost by subsidence, and the colours themselves were very liable to rub. Another point was that the price of antimony oxide had nearly trebled in the last two years, and this had the effect of making the relative difference of cost of the antimony lactate and antimony fluoride not so great.

Mr. Williams, in reply, said he thought Mr. Claflin had well presented the other side of the question, and, as he stated in the conclusion of his paper, the final test was that of practical result under actual working conditions.

Nottingham Section.

Meeting held at Nottingham on Wednesday, March 28th, 1905.

Mr. J. M. C. Paton in the Chair.

THE DEPRECIATION OF PLANT AND MACHINERY

By H. Stanley Garry, C.A.

The subject of depreciation is one to which increasing attention is now being paid, and there is, perhaps, no class to whom it appeals more forcibly than those connected with chemical industries. It is a subject moreover which, while generally accepted in principle, has given rise to great divergence of opinion in details. Some considerable confusion exists, however, through a want of clearness in definition, and it will be well, therefore, in bringing this subject before you for discussion to clearly define, in the first place, what is intended to be covered by the word "Depreciation."

It is now generally recognised that the wastage of capital invested in plant and machinery is as much a working expense as the labour which operates it, and forms an equally definite part of the cost of production. It is also recognised that this wastage proceeds from a variety of causes differing in effect. We may enumerate these as follows:

Wastage by deterioration.—While a machine or plant may be renewed and repaired in part, and may be made practically efficient in working, there is a slow but inevitable depreciation taking place, which sooner or later extinguishes its capital value.

Wastage by obsolescence.—Under this head, the plant or machinery may be rendered obsolete by reason of its being superseded by an improved type of machine, or partially by reduction in the price after purchase, or by scientific discovery which may render the whole, or any part of a plant obsolete, owing to the changes in process or manufacture.

These divisions are practically final in their effect.

The term "depreciation" is also used to cover an annual provision in anticipation of the expense of the renewal of the machinery and plant at some future period. Some authorities would carry the matter still further, and include under the head of depreciation a provision against the possible diminished value of the plant and machinery which may occur by reason of the changes in markets and trade. In some cases, the life of machinery and plant may be dependent on the period of a patent. These, however, are matters which are, perhaps, more properly dealt with in the light of reserves, to be provided for before distribution of profits, and are not risks which affect solely the plant, but also the other items of a balance sheet.

We have, therefore, to consider an annual charge for depreciation to provide for:—1, deterioration; 2, renewals; 3, obsolescence. I purpose dealing here with the subject of depreciation under these heads as affecting —1, cost of production; 2, income tax; 3, fire insurance.

With regard to the two primary heads of deterioration and obsolescence, we may describe the effect of these on the life of the plant, as deterioration or death from natural causes, and obsolescence as accidental death.

This illustration is, perhaps, homely, but if you will consider it in the light of insurance, you will more readily appreciate the difference in the risks and the annual premium involved therein.

Residual value.—In dealing with the estimated life of plant and machinery, we have to take into account the residual value of the machinery or plant when its period of usefulness has expired, and in dealing with plant of a special nature, it may be generally assumed that, in proportion to its special character, its residual value will be low. In plant of a general character, as engines, boilers, shafting, pulleys, &c., in the event of displacement, its residual value will be high.

Method.—In like manner when we come to deal with the plant as a whole for the purpose of assessing the annual provision for depreciation, we find that the considerations affecting deterioration, renewals, and obsolescence differ greatly according to the character of the plant.

There are two extreme methods of valuation:—

1. The method of assuming an average per centage rate covering the whole plant of, say, 5 to 7½ per cent. on the book value.

2. The individual valuation of each machine, and the writing off of the detailed differences.

Both these methods are faulty. In the first method, the result is hazardous, as the percentage may be assumed on a proportion of general and special plant which may vary considerably afterwards. In the second place, the detail is very considerable. It has to be done at a time of pressure, and if left to other hands than that of a principal, the results are generally too favourable.

In arriving at a basis, therefore, for the settlement of a depreciation charge, it will be found generally desirable to classify the plant, and by taking the plant and machinery in each department and abstracting the items of each under five or six classes, we shall get, in the first place, a departmental separation, and, secondly, a classification under each department of, say:—

Motive power.—Boiler, engines, &c.

Prime movers.—Shafting, pulleys and transmitters.

Process plant.—Fixed, wearable, loose.

Accessory.—Railway trucks, weighing machines, travellers, cranes and the like.

By leaving space in each department inventory, we can provide for additions, and by having loose sheets with columns for abstracting, we can economise in re-writing.

Having obtained our totals thus, we can then apply to each department and sub-division a separate rate in respect of deterioration, obsolescence and renewals, based on our experience. The particulars thus obtained will also afford a basis for the charges in our cost sheets, as we shall thus obtain a departmental depreciation charge. We can then adopt a fixed rate.

Diminishing value.—Before we can proceed to establish a percentage rate on these classes of plant, we must settle the basis on which the rates are to be calculated.

For some years, the basis of the diminished value obtained by the writing off of the annual depreciation charge has been generally adopted, but during the last few years, there has been a tendency to revert to the basis of original cost. For instance, a rate of 10 per cent. on the original cost will exhaust the value in 10 annual instalments, but a rate of about 16½ per cent. would be required to exhaust the value in the 10 years if calculated on the diminishing value remaining after the deduction of depreciation in each year.

The argument in favour of basing the calculation on the diminishing value, is that the sums written off in the earlier years were greater when the repairs were small, and that thus tended to equalise matters. Too often, however, the two factors of rate and basis have not been settled together, and in consequence, the adoption of the basis of diminishing value has had the effect of leaving a considerable value in the books when the plant has disappeared.

For instance, a 5 per cent. rate generally carries the impression of a 20 years' life, yet taking £100 as cost and writing off on the diminishing value, the balance left at the end of the twentieth year is £37 14s. We cannot assume that the residual value in the plant, after 20 years' service, would be a third of the value, and it will be seen that there is room here for considerable error. Not only so, but if we adopt original cost the position is much clearer for any revision of the rate at any subsequent period.

Depreciation rates.—Dealing with these sub-divisions of the plant in order, we have:—

Motive power, boilers, engines, &c.—Some authorities place the depreciation on engines as high as 12½ per cent. and boilers at 10 to 15 per cent. Much depends on the stress of working and the water. Matheson places the life of a boiler at 15 years, with renewal of the furnace at the end of 10 years, and recommends a rate of 7½ per cent. per annum on the diminishing value on this class; no provision being made for obsolescence. This is, however, an extreme view.

Prime movers.—Shafting, pulleys and the plant under this head have, as a rule, a high residual value even if displaced, and probably a rate of 5 per cent. will be sufficient provision. Belting should be classified as loose tools. In this class, authorities would recommend the adoption of a rate of 5 per cent., which may be divided into 3 per cent. for deterioration and a renewal rate of 2 per. cent. No provision for obsolescence is made herein.

Process plant fixed.—Under this head we would place all heavy process plant, the wearable and renewal portions of which are classified under their separate heading. The deterioration would then be met by a rate of 2½ per cent., the renewal rate at 2½ per cent. An obsolescence rate dependent on the nature of the processes.

Process plant wearable.—Under our classification we have already dealt with the exteriors of this plant and we have, therefore, to provide a heavy renewal rate. By the dissection of this plant under the shop totals we shall have already secured the separation of the different process plants and can readily apply to each shop total a distinctive rate for renewals applicable to its character and requirements. This will be readily based on experience.

Process plant loose.—In the case of loose tools, the valuation yearly gives the most reliable results. In some cases there is an annual increase in this class, but this should verify itself. It is to be remembered that at a going-concern valuation this cannot, in the nature of the plant, work out at much more than half the original cost value.

Accessory plant.—In this case we have a high residual value due to general utility and consequently a rate for deterioration of 2½ per cent., and a renewal rate of 2½ per cent. should suffice.

Horses, carts, harness, &c.—The risks and depreciation on this class are too great to include in any average rate. The treatment accorded to loose tools of revaluation annually gives, probably, the best results.

Depreciation and income tax.—In order to avoid repetition and as the problems in connection with income tax and fire insurance are mainly connected with the rate of depreciation, it will be well to deal, at this stage, with these aspects of the subject. It is to be noted, in the first place, that from the very earliest periods of income tax assessment, the law has always dragged far behind its administration in regard to the allowance of depreciation.

The Report of the Departmental Committee on Income Tax, issued in June, 1905, states that the Committee are of opinion that no substantial change is called for in respect to the allowances for depreciation, a conclusion which could only be expected from the official character of the Committee, and which is further evidenced by their opinion that the income tax, as a whole, is levied with a minimum of friction and a maximum of result. The labours of the Committee have, however, provided evidence of the sharp contrast with which this subject is viewed from the official and commercial standpoints. The official standpoint is summed up by an official witness in the statement that the income tax is a tax on income and not on profits. The commercial standpoint, on the other hand, is summed up by a commercial witness in the statement that income tax should be levied only on profits distributed in dividends as the basis of actual income.

The rate of depreciation allowed under the Income Tax Acts differs considerably in different localities, a result which is stated to be due to a want of knowledge on the part of manufacturers as to their rights. It would certainly appear that there is considerable scope on the part of some body representative of the chemical industries to take up the question of depreciation and to obtain the most-favoured-nation clause in the assessments with regard to this.

For instance, the rate of depreciation allowed to engineers in Leicester is 7½ per cent. on the full value, while in Cardiff the rate is only 5 per cent. on the diminished value. Hosiery machinery in Leicester obtains 7½ per cent. as against 5 per cent. on lace machinery in Nottingham. Dyers' machinery in Leicester can get 10½ per cent. if justified on enquiry. Generally speaking, a distinction is made between motive power and process plant, and the general practice assumes 5 per cent. on motive power and 7½ per cent. to 10 per cent. on process plant. The foregoing allowances are, however, in respect of our two headings of deterioration and renewals.

With regard to obsolescence, there appears to be no annual allowance at present possible in respect of this, but where claims are made specifically under this head, an allowance is made from the assessment for plant which is scrapped to the full amount at which the same stood in the books at the previous stocktaking.

With regard to horses, no allowance is made for these, but the full cost of replacement is to be charged as they occur.

Fixtures.—No allowance is made for depreciation on fixtures, unless these are included under the head of

plant. Any replacements are allowed in full against the year's working.

It is to be noted, as evidence of the interest now taken in securing the allowances for depreciation, that whereas in the year 1893–4 the depreciation allowances were only £4,109,207, they have steadily increased until in 1902–3 they have reached £12,707,580.

The arguments used in connection with depreciation as regards income tax may be regarded somewhat as special pleading, but it may be of interest to summarise the grounds specified by the Associated Chambers of Commerce in 1897, for an increase in the rate of allowance.

1. That machines become obsolete much more quickly to-day than formerly.

2. That the value of machines diminishes more rapidly.

3. That the first purchasers pay a heavy premium on new machines, and, after a year or two, could purchase superior machines at half original price.

4. That machinery is worked at higher speed, wears out sooner, and is more rapidly depreciated to-day than formerly.

With regard to the basis of diminishing value, it is to be noted that the Inland Revenue authorities have now reverted in a number of cases to the basis of original cost, and that where, say, 5 per cent. is allowed on original cost, there is often an alternative rate of 7½ per cent. allowed on the diminishing value.

Renewals.—The practice adopted by the Income Tax authorities provides for the charging up of renewals to capital account where depreciation is allowed, and they usually decline to allow both renewals and depreciation as a charge against the year's profits. The result is to treat renewals as capital expenditure, which in turn are subject to depreciation at the rate agreed on. If we take Mathieson's example of the life of a boiler at 15 years, at the end of 10 years, of which we have to renew the furnaces, it will be seen that by charging renewals to capital, we can only provide for 25 per cent. of the cost of the renewal before the expiration of the life period. Therefore, if we are to charge renewals to capital, it is evident that in our calculation of the rate of depreciation we must include the provision for renewals along with deterioration.

The tendency to-day is to separate renewals from depreciation and to provide a fixed sum annually against renewals and repairs, charging the outlay each year under both these heads against the sum thus accumulated, and leaving depreciation to include deterioration and obsolescence only.

Fire insurance and depreciation. The point has been mentioned that in the case of writing down machinery and plant by an increased rate of depreciation, the value in the case of a fire would be affected in the claim for replacement.

Upon enquiry, I am informed that it is usual, in some offices, to append a declaration on the face of the policy that the depreciation written off in the books of the business shall not be taken for the purpose of assessing a fire loss. I am also informed that the assured is covered for the value of the plant at the time of the fire, and that the original cost of the plant, less depreciation, is not necessarily the basis of the claim.

There does not appear to be any scale of depreciation in force for different kinds of plant recognised by the insurance companies, but as these losses are generally settled as between the assessors and surveyors, acting for both parties, or failing their agreement by arbitration, no special rates are applicable, but each case is settled on its merits. The principal factor appears to be the possession of definite and specific information on the value and cost of the plant, and so far as I have been able to gather, the rate of depreciation adopted by the insurer does not, in any way, govern the claim in case of fire.

It is to be noted that it is a general provision in fire insurances and policies that the company may elect to replace the plant. I have not been able to discover any instance where this has been done, and probably it was never intended as other than a protection to the company.

Turning back to the consideration of the subject generally, we have now dealt with the adoption of rates as regards cost purposes, we have compared the rates allowed for income tax purposes and we shall probably have arrived at the conclusion that the allowances for income tax are in no way to be regarded as a standard of the depreciation rates necessary for business purposes.

There exists some considerable controversy as to the proper authority to fix the rate of depreciation. One engineering author considers it unfortunate that the subject of depreciation is generally settled by the auditors, and claims that only an engineer can understand it. A similar claim is put forward by professional machinery valuers, on the ground of their independent position and general trade knowledge. The engineer is, no doubt, the best authority on deterioration. The chemist (as manager) is probably the best authority on renewals and probably both for obsolescence, while for financial considerations, the auditors take the first place.

In the evidence given by Mr. Arthur Chamberlain, of Birmingham, representing the Birmingham Chamber of Commerce, before the Income Tax Committee, he states, somewhat emphatically, that he would prefer to be guided by the financial expert on the subject of depreciation rather than by either his engineer or a professional machinery valuer, on the ground that the true test of the value of the plant is its earning power.

This brings us to the consideration of my last point:

Financial depreciation.—You will, perhaps, remember that in the opening remarks, we referred to the diminished value of machinery, due to the changes in markets and trade, which includes the action of foreign tariffs.

We have already dealt with deterioration, renewals and obsolescence, and we have still to take a general survey of the plant and machinery item with regard to its position from the point of view of earning power.

The argument put forward is that the plant and machinery asset tends to increase as time goes on, until it obtains an undue and predominating position, that as profits always tend to a minimum, the value of the plant and machinery item in all businesses requires to be steadily diminished if the ratio of profits to capital is to be maintained in future years.

From this point of view, the ideal condition would be, if we take the case of a new plant, that the capital account is to be closed immediately the installation is completed. After that, all additions, renewals and repairs are to be provided out of profits, and in addition, the value of the asset is to be written down annually.

The answer to this is, that if this ideal of depreciation were to be seriously proposed, it would be very few businesses which could be carried on. The reply is that in the history of the great number of businesses which have disappeared, their ruin began when the value of their plant, machinery and buildings steadily increased, even although their productive capacity followed. That the insufficient depreciation was a more potent factor in their downfall than either prices or markets. That prices and markets are dependent on new machinery, and that the obtaining of new machinery depends primarily on the sufficiency of the depreciation.

In this connection, the rates of depreciation in force in the United States would appear to be greater than in this country, and that there are not wanting prophets who trace the alleged falling off in the position of the English manufacturer in the world's market, due primarily to the insufficient depreciation of plant.

In conclusion, I have endeavoured to put before you in as brief a form as possible a summary of the opinion of authorities to-day on this subject. There is a tendency to-day to allow a larger provision for depreciation than was formerly deemed necessary, and to admit the importance of depreciation of plant and machinery in industrial economics to a degree never contemplated by a past generation.

Composition of matter [for protecting packings from the action of lubricating oils]. L. S. van Westrum, Berlin, Germany. U.S. Pat. 814,750, March 13, 1906.

A COMPOSITION consisting of 5 parts of castor-oil, 3 to 4 parts of fine graphite, and 1 to 2 parts of caustic lime is claimed. It is used to prevent packings from being attacked and dissolved by petroleum or equivalent lubricants.—W. H. C.

Extraction vessel. C. M. Chamberlain, Lead, S. Dak. U.S. Pat. 814,940, March 13, 1906.

A LONG tank is supported in a horizontal position by trunnions, so that it can be inclined, and one or more trays, provided with filter beds, are fixed longitudinally within it. The tank has removable ends, one of which is provided with a discharge gate or gates, corresponding to and forming one end of the trays.—W. H. C.

Kiln. R. W. Stewart, Findlay, Ohio. U.S. Pat. 815,387, March 20, 1906.

THE claim is for a kiln chimney which has two separate flues—a "main or fire flue," which takes air from the exterior of the kiln, and a supplementary flue within and surrounded by the main flue and which communicates at its upper and lower ends with the interior of the kiln.—W. H. C.

Kiln. R. W. Stewart, Findlay, Ohio. U.S. Pat. 815,388, March 20, 1906.

THIS is a modification of the preceding patent, in which the supplementary flue surrounds the main flue on three sides.—W. H. C.

Distilling apparatus. G. F. Wentz, St. Louis, Mo. U.S. Pat. 815,392, March 20, 1906.

THE claim is for the combination of a steam generator with a condenser and a water reservoir. A water-supply pipe connects the lower portion of the condenser with the lower portion of the reservoir, and a water-return pipe connects the top of the former with the top of the latter. The steam generator is a cylindrical vessel, having a hand-opening above provided with a cap, from which a pipe leads the vapours to the condenser, and an inclined bottom, in which there is a tap for drawing off sediment. Water is supplied to the generator through a pipe connected to the water-return pipe, between the condenser and the reservoir, and which is controlled by a valve, operated by a crank attached to a float in the generator, and provided with a nozzle to direct the water with a gyratory motion on to the bottom of the generator.—W. H. C.

Filter [Iron-hydrogen alloy]. H. C. Gesner, New York, N.Y. U.S. Pat. 815,417, March 20, 1906.

THIS invention relates to a filter consisting of a porous coherent body of agglomerated particles of an alloy of iron and hydrogen made in the form of a rigid plate or tube.—B. N.

Filtering material. O. Löffler and W. Weidle, Vienna. U.S. Pat. 815,846, March 20, 1906.

SEE Eng. Pat. 6055 of 1905; this J., 1905, 937.—T. F. B.

FRENCH PATENTS.

Distillation of liquids, Process and apparatus for the continuous ——. J. Fischer. Fr. Pat. 359,533, June 22, 1905.

THE apparatus is shown in longitudinal vertical section in Fig. 1, in horizontal section on the line, *x*, *x'*, in Fig. 2, and in vertical cross section along the line, *y*, *y'*, in Fig. 3. The liquid to be distilled enters the apparatus by the pipe, *g*, into the bottom of the chamber, *c*, from which it flows through the chambers, *c*, formed by the partitions, *b*, being compelled to take a circuitous course by the vertical baffles, *j*. The vapours rise into the head, A, and escape by the opening, *a*, whilst the residual liquid collects in the chamber, *c'*, from which it flows to a second apparatus or to a tank, by the pipes, *h*. The gaseous heating medium enters through, *m*, into the chamber, *c'*, passes up the channels, *d*, over the baffle, *k*, and down the channels, *d'*, giving up its heat to the liquid in the chambers, *c*, passing finally into the chamber, C, from which it either goes to a second apparatus through the passage, *n*, controlled by the damper, *n'*, or by the passage, *o*, controlled by the damper, *o'*, to the flue. The apparatus is supported on a base, D, and the heating may be increased by injecting liquid fuel through *p*.

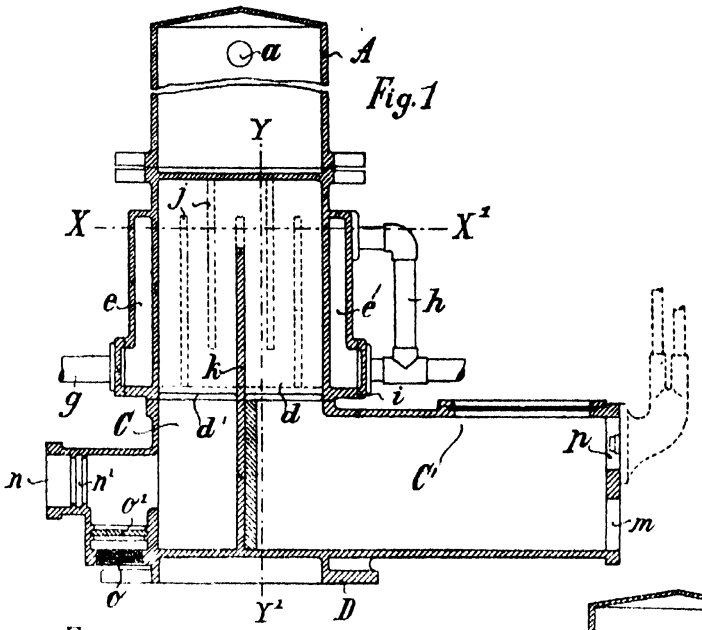

Fig. 1

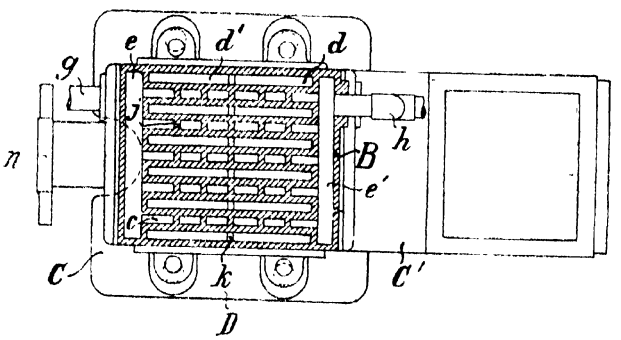
Fig. 2



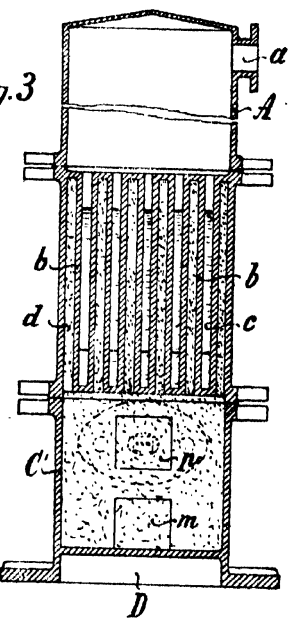


Fig. 3

Modifications of the apparatus are claimed, and it may either be used singly or several may be combined into a battery.—W. H. C.

Inflammable liquid, or liquids which give off inflammable vapours; Process for moving ——. C. Martini and H. Huncke. First Addition, dated Oct. 31, 1905, to Fr. Pat. 337,733, Feb. 28, 1903. (See Eng. Pat. 4233 of 1903; this J., 1904, 14.) Under Int. Conv., May 15, 1905.

The present Addition relates to the regulated addition of carbon dioxide or other inert gas to the exhaust gases from an explosion engine which are used to effect the movement of the fluids in question. The regulation is effected by a valve which is intermittently opened or shut by a lever attached to the shaft of the gas engine.

—W. H. C.

Drying; Process and apparatus for ——. A. H. Messinger and V. Popper. Fr. Pat. 359,594, Nov. 18, 1905.

See Eng. Pat. 25,871 of 1905; this J., 1906, 304.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 308.)

Calcium hydride; Industrial production of ——. G. F. Jaubert. Comptes rend., 1906, **142**, 788—789.

Metallic calcium is prepared by electrolysing the fused chloride, and is then heated for some hours to a high temperature in an atmosphere of hydrogen. The product is a white or grey, hard, porous solid, containing about 90 per cent. of the pure hydride. It is readily decomposed by water, 1 kilo. evolving nearly 1 cb. m. of hydrogen. It is proposed to use it in producing hydrogen for balloons.—J. T. D.

ENGLISH PATENTS.

Burners for liquid fuel. J. W. Morton, Carluke, N.B. Eng. Pat. 4933, March 9, 1905.

IN a burner for liquid fuel, operating by means of a steam-propelled spray, the spraying nozzle is fitted with a two-way connection, one branch of which leads to the boiler in which the burner is generating the steam, whilst the other is connected to a small independent boiler. On starting to use the burner, steam can be raised quickly in the small boiler, which is then kept in operation until a sufficient supply of steam is obtained from the large boiler, whereupon the valve connecting the small boiler is closed. (Reference is directed to Eng. Pats. 4046 of 1886 and 15,270 of 1904.)—H. B.

Gas-producing plants. [*Enriching producer gas*]. H. G. Hills, Romiley, Cheshire. Eng. Pat. 9171, May 2, 1905.

IN order to render producer-gas, generated in a suction producer, suitable for use in a gas engine which is designed for operating with ordinary coal-gas, the producer gas, in passing from the producer to the engine, is carburetted in the usual manner by drawing it through a vessel containing absorbent material, impregnated with benzol or the like. It is claimed that the calorific value of the gas is thus raised from 130—150 up to 500 B.T.U.
—H. B.

Gas calorimeter; Recording —. C. H. Beasley, Smethwick. Eng. Pat. 10,721, May 23, 1905.

A U-SHAPED tube, one limb of which is enclosed within a vertical chimney, is provided at the top of each limb with a small tank, and contains enough oil, or other suitable liquid, to fill the tube and partly fill the two tanks. The gas to be examined, is burned in an atmospheric burner at the bottom of the chimney, and the oil in the heated limb of the U-tube rises to a level above that in the other limb corresponding to the temperature attained. The difference in level is, therefore, a measure of the calorific value of the gas, and is recorded automatically by means of two floats situated in the tanks, and connected by threads or metal strips to two pulley-wheels arranged upon a horizontal spindle. The spindle rotates as the floats rise and fall respectively, and operates a lever carrying a marker, the latter tracing a diagram upon a moving band of paper, actuated by clockwork and ruled with a scale which indicates directly the calorific values.—H. B.

Minerals [*Coal*]; *Apparatus for cleaning and separating* —. G. F. Zimmer, London. Eng. Pat. 13,955, July 6, 1905.

THE crushed coal is made to pass along a vibrating conveyor trough, fitted with a corrugated bottom at the feed end and having a succession of false bottoms consisting of perforated plates, woven wire or grids, alternating with outlets for the removal of the waste. Adjustable weirs and apertures are also provided in the bottoms of the troughs, whereby the material is gradually sized and cleaned as it is carried along the trough.
—J. H. C.

Coal and other minerals; Apparatus for washing and separating —. D. Campbell, R. B. J. Binnie and W. Reid, Hamilton, Lanark. From J. Smith, Hatting Spruit, Natal. Eng. Pat. 26,556, Dec. 20, 1905.

IN jigging, a clearing arm or finger is provided which projects into the stone-trap. Arrangements are made for moving this arm at intervals so as to prevent the trap from becoming choked.—J. H. C.

Burning liquid fuel; Apparatus for —. J. W. Morton, Carluke, N.B. Eng. Pat. 4931, March 9, 1905.

THE liquid fuel is sprayed from a nozzle into a chamber having a tortuous passage in the form of a bend or spiral, which promotes the vaporisation of the fuel and its admixture with the air which enters the chamber along with the jet of fuel. A baffle-plate, of conical or other suitable form, is fixed above the outlet from the chamber, to render the combustion more perfect. The chamber is constructed of refractory material, such as fireclay.—H. B.

Gas; Process and apparatus for producing coal —. P. Busse, Crosta, Saxony. Eng. Pat. 4956, March 9, 1905.

SEE Addition of March 14, 1905, to Fr. Pat. 348,411 of 1904; this J., 1905, 1007.—T. F. B.

Gas-making plant; Impts. in connection with the hydraulic mains of — *for collecting pitch therefrom.* J. Y. Johnson, London. From Deutsche Continental Gas-Ges., Dessau, Germany. Eng. Pat. 17,464, Aug. 29, 1905.

WITHIN the hydraulic mains of gas-making plants, removable scoops or the like are arranged beneath the ends of the dip pipes, for collecting the pitch dropping therefrom, the scoops being withdrawn when filled, and replaced by empty ones. The arrangement is specially applicable to mains provided with a longitudinal inclined sealing partition, forming a separate longitudinal inclined chamber provided at the top with a series of apertures and covers; through these apertures the scoops can be inserted or withdrawn, without interrupting the gas manufacture.—H. B.

Gas engines; Process for the utilisation of the waste heat of marine — *for the production of steam from sea water for feeding gas generators.* E. Capitaine, Germany. Eng. Pat. 22,594, Nov. 4, 1905. Under Int Conv., Nov 5, 1904.

THE hot exhaust gases from the engine, or hot gases from the gas generator, are led down through the tubes of a boiler, or heat interchanger, producing steam from the sea-water contained therein. The steam is utilised in the gas generator. A constant flow of fresh sea-water takes place into the interior of the boiler through a tubular coil arranged within an annular jacket surrounding the boiler. A corresponding constant stream of the boiling, merely slightly concentrated, sea-water flows out from the top of the boiler into the said jacket, and, on its way to waste, parts with its heat to the fresh water flowing in through the coil.—H. B.

Coal gas and other gases, Process and apparatus for washing or purifying —. E. Ott, Zurich, Switzerland. Eng. Pat. 5773, March 18, 1905.

SEE Fr. Pat. 352,565 of 1905; this J., 1905, 961.—T. F. B.

Incandescent light; Process of generating —. R. Mewes, Berlin. Eng. Pat. 5265, March 13, 1905.

HYDROGEN, coal-gas, or other combustible gas, and oxygen, the air, or other gas used as supporter of combustion, are enriched by the addition of volatile, combustible or incombustible compounds, "such as calcium ethyl, calcium methyl, calcium ethylate, magnesium ethyl, silicium ethyl, silicium ethylate, borax ethyl, aluminium ethyl, aluminium ethylate," for the purpose of obtaining light by the incandescence of the liberated particles of metallic oxide, &c., without the intervention of a mantle. Burner jets, from which the enriched gas and air respectively issue, are arranged at suitable angles to each other. If desired, however, the flames may be directed upon the surface of a mantle or other suitable solid body.—H. B.

UNITED STATES PATENTS.

Gas producer. A. Cerasoli, Rome. U.S. Pat. 815,794, March 20, 1906.

SEE Eng. Pat. 20,678 of 1903; this J., 1904, 816.—T. F. B.

Gas producer. C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 815,913, March 20, 1906.

A GAS producer is combined with a fuel-burning furnace by a pipe connecting the waste-gas outlet of the furnace with the producer. This pipe is provided with a valve-controlled air inlet, open to the atmosphere, and with an air injector between the inlet and the producer.—R. L.

Gas generator. J. Radcliffe, Elland. U.S. Pat. 816,123, March 27, 1906.

SEE Eng. Pat. 7592 of 1904; this J., 1905, 490.—T. F. B.

Gas-purifier. F. G. Hobart, Beloit, Wis., Assignor to Fairbanks, Morse and Co., Chicago, Ill. U.S. Pat. 814,698, March 13, 1906.

THE purifier described is for gas or liquid, and consists of a shell or casing, in which are a number of removable trays, closely fitted in the casing and dividing it into compartments. In each compartment, filtering material is placed on the trays. A pair of pipes rest on the bottom of the casing, and pass vertically upwards through the trays, which fit closely round the pipes. One of the pipes has inlet ports on one side of the trays, and the other outlet ports on the other side of the trays. The pipes pass through apertures in the cover at the top of the casing. —W. C. H.

Vacuum lamps; Method of producing —. D. M. Moore, Newark, N.J., Assignor to Moore Electrical Co., New York. U.S. Pat. 814,794, March 13, 1906.

IN the process described for manufacturing vacuum-tube electric lamps, the interior of the tube is coated with an organic substance, such as a hydrocarbon, which is electrolysed in order to form an adherent coating of "fixed solid residue," on the interior. While the electrolytic process is being carried on, the tube is exhausted and finally sealed off when the decomposition is practically complete.—W. C. H.

FRENCH PATENTS.

Fuel; Agglomeration of —. [*Utilisation of waste cellulose lyes.*] A. E. Tavernier and C. Oulman. Fr. Pat. 359,249, Nov. 8, 1905.

WASTE cellulose lyes from paper manufacture are treated with sulphuric acid and concentrated to a syrupy consistency, then well mixed with about 20 parts of the previously ground and sifted fuel. The mixture is heated for 10 minutes with direct steam, then formed into a paste and pressed in a briquette press under a pressure of 200 kilos. per sq. cm. The briquettes are dried in a chamber built of bricks and covered with red lead. Vapours of hydrochloric acid are passed through the chamber. By the action of the acid the cellulose is transformed into carbon and thus made insoluble. The hydrochloric acid vapours are received in water and used again.—R. L.

Burner; Liquid fuel —. C. Leistner. Fr. Pat. 359,355, Nov. 9, 1905. Under Int. Conv., Nov. 10, 1904.

SEE Eng. Pat. 24,372 of 1904; this J., 1906, 114.—T. F. B.

Gas generator. W. Towns. Fr. Pat. 359,203, Nov. 7, 1905. Under Int. Conv., July 8, 1905.

SEE Eng. Pat. 14,090 of 1905; this J., 1905, 1163.—T. F. B.

Gas-retort furnace. W. Bäcker. Fr. Pat. 359,255, Nov. 8, 1905.

THE furnace is circular in plan, and comprises a series of vertical retorts arranged like a ring in an annular chamber in the masonry. In the centre, and below the level of the retorts, are a number of generators, the gases from which are led through numerous flues into the annular retort-chamber, where they burn on encountering streams of preheated air. The chamber is sub-divided by partitions to cause the hot gases to pursue a zig-zag course round the retorts, and the waste gases finally pass off by a central chimney.—H. B.

Gas washer. Cie pour la Fabr. des Compteurs et Matérial d'Usines à Gaz. First Addition, dated Nov. 6, 1905, to Fr. Pat. 356,721, of Aug. 7, 1905 (this J., 1906, 11).

THE washing wheel referred to in the principal patent is here modified, by substituting discs of glass, arranged upon a rotary metal shaft and spaced apart by means of leather washers, for the sectors of glass, arranged radially round the shaft, as therein described. To prevent fracture of the glass discs by striking against the walls of the washing chamber as the shaft carrying the discs is lowered into or raised from it, each end of the shaft is provided with a vertical guide rod which sinks into a vertical pit or channel in the masonry, keeping the discs clear of the latter.—H. B.

Gas washing and purifying apparatus. Kirkham, Hulett and Chandler, Ltd., and S. Hersey. Fr. Pat. 359,276, Nov. 9, 1905. Under Int. Conv., Nov. 11, 1904.

Gases; Apparatus for [automatic] analysis of —. Monopol Betriebskontroll-Apparate K. Stembock. Fr. Pat. 359,352, Nov. 2, 1905. XXIII., page 395.

Filaments of iridium for incandescence lamps; Apparatus for baking —. R. J. Gulcher. Fr. Pat. 359,162, Nov. 4, 1905.

THE apparatus is designed for annealing iridium filaments, obtained by mixing finely-divided iridium with an organic agglutinant material, forming the mixture into filaments, drying the latter and reducing them in a current of hydrogen. An annular oxyhydrogen burner is suspended on a carrier between two vertical guides, and can be caused to ascend or descend between the guides by means of attached cords, working over pulleys at the top of the guides and connected to a winding spindle at the base of the apparatus. The burner consists of two concentric conical chambers, to one of which oxygen is led, to the other, hydrogen, by means of flexible tubing; an annular flame is thus produced, whilst the central space admits an upward current of air, and allows the iridium filament to pass through, as the burner rises or falls. The filament is suspended vertically from a thick platinum wire, so as to be in the centre of the flame, and the burner is raised and lowered as often as desired, to bake the filament throughout its length.—H. B.

Incandescence bodies for electric lighting; Process of making — by producing a metallic deposit on a metal core. Siemens und Halske Act.-Ges. Fr. Pat. 359,339, Nov. 11, 1905. Under Int. Conv., Nov. 15, 1904.

SEE Eng. Pat. 23,097 of 1905; this J., 1906, 115.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 309.)

Pine wood; Products of the distillation of —. W. H. Walker, E. W. Wiggins and E. C. Smith. J. Amer. Chem. Soc., 1906, 28 (Abstracts) 103—105.

THE distillation was effected in a retort made from a 12-in. wrought iron pipe surrounded by a 14-in. pipe serving as jacket. Superheated steam was passed through the jacket and the interior of the charge, the distillation being started at 175° C., whilst after the oil of turpentine and rosin oil had come over, the temperature was raised gradually to 400° C. It was found that heart-wood was of little value for the production of turpentine as compared with stump-wood. The turpentine obtained gave 80 per cent. of distillate below 163° C., had a sp. gr. of 0·865 to 0·867, and showed a specific rotatory power of +28·7°. It contained very little free acid and less than 1 per cent. of non-volatile matter. The crude rosin, after heating to 150° C. to expel moisture, solidified to a hard mass with clear vitreous fracture and of almost black colour. It was, therefore, converted into rosin oil, when the following products were obtained:—

	Per cent.	Sp. gr.
Acid liquor	15·34	—
Rosin spirit	4·20	0·930
Rosin oil	26·47	0·990
Blue oil	17·91	0·994
Green oil	16·62	1·030
Tar	4·62	—

In another series of experiments, the wood was subjected to dry distillation with the following results :—

	Weight of wood. Kilos.	Gas. Per cent.	Crude product. Per cent.	Tar. Per cent.	50 per cent acid Per cent	Oil Per cent.	Charcoal. Per cent.
I	2·2	43·0	34·2	19·5	1·18	3·0	23·9
II	2·0	28·7	46·9	25·9	1·70	2·5	24·5
III.	2·0	25·9	39·6	19·8	1·32	2·6	34·5
IV.	2·0	24·1	51·4	26·8	1·86	3·6	23·3

The first run was made at 300° C. for two hours, whilst in the last three runs, the retort was heated slowly to 175° C. for one hour, after which the temperature was raised to above 300° C. The following are the yields calculated on a cord of light wood of 6000 lb. :—

From steam distillation :

		Yield. Per cent.
Oil of turpentine	24·9 galls.	3·00
Yellow oil	4·4 ,,	0·56
Rosin	318 lb.	5·30

From dry distillation :—

		Yield. Per cent.
Gray acetate of lime	46·2 lb	—
Light oil	18·4 galls	2·31
Charcoal	1050 lb	17·50
Gas	3750 cb ft	2·00
Wood tar	1217 lb	20·28

—D. B.

Louisiana petroleum ; The series C_nH_{2n-2} in ——. C. E. Coates. J. Amer. Chem. Soc., 1906, **28**, 384—388.

JENNINGS oil furnished a small quantity of a fraction, $C_{11}H_{20}$, having an odour of turpentine, and ultimately, after repeated fractionation under a pressure of 21 mm. the following series was obtained :—

Probable formula.	Mol. wt.	C.	H.	Sp. gr.	B.P. at 760 mm C	n_D^{25}	Mol. refraction.
		per cent	per cent				
C_9H_{14}	111	—	—	$0{\cdot}774^{24}_{4}$	120·5	1·4260	—
C_9H_{16}	121	—	—	$0{\cdot}790^{23}_{4}$	145·7	1·4370	—
$C_{10}H_{18}$	138	86·81	13·01	$0{\cdot}814^{22}_{4}$	168–170	1·4460	44·96
$C_{11}H_{20}$	151	87·00	12·88	$0{\cdot}837^{20}_{4}$	198–200	1·4582	48·76
$C_{12}H_{22}$	167	86·68	13·43	$0{\cdot}851^{18}_{4}$	215–217	1·4640	53·48
$C_{13}H_{24}$	181	86·58	13·42	$0{\cdot}862^{22}_{4}$	235–238	1·4692	57·98

Despite the turpentine smell, all the above were optically inactive and gave no evidence of unsaturation under the usual tests. The properties of the hydrocarbon, $C_{10}H_{18}$, correspond with those of a methylbicyclononane, but the sp. gr. is too high. The hydrocarbon, $C_{13}H_{24}$, however, corresponds almost exactly with an isopropylmethylbicyclononane. The series appears to be a homologous bicyclic one beginning at least as low as $C_{10}H_{18}$ and having some connection with asphaltum, since a considerable portion of the oil was condensed to a semi-asphaltic mass on being passed through a red hot copper pipe and suddenly cooled.—C. S.

Dimethyl sulphate for determining tar oils in admixture with rosin and mineral oils, and its behaviour towards fatty oils, oil of turpentine and pinoline. E. Valenta. Chem.-Zeit., 1906, **30**, 266—267.

THE fraction from coal tar boiling at 240°—300° C. is often used to adulterate mineral oils and more frequently printers' ink. For its determination, dimethyl sulphate is recommended, which dissolves the hydrocarbons of the benzene series readily in the cold, but does not act on petroleum distillates and rosin oils. In the method described, a known volume of the oil under examination is added to a suitable volume of dimethyl sulphate (one and a half to two parts) in a stoppered glass cylinder of about 100 c.c. capacity, graduated so that each division equals 0·5 c.c. The contents are well shaken for about one minute and left to rest until the two layers have completely separated, when the increase in the volume of the lower layer indicates the quantity of coal-tar hydrocarbon oil taken up by the sulphate.

For the estimation of tar oils in printers' ink, the lampblack contained therein is separated in the usual manner. If the varnish contain saponifiable products, 25 c.c. are then evaporated to dryness on the water-bath with 125 c.c. of an alcoholic caustic soda solution (80 grms. in 1 litre of 95 per cent. alcohol). The residue is dissolved in 250 c.c. of hot water, the solution well shaken with 100 c.c. of ether, and this operation repeated two or three times. The ethereal solution containing the hydrocarbons is washed with water, the ether expelled by evaporation in a tared platinum dish, and the residue dried and weighed. A measured volume is then treated with dimethyl sulphate.

By the treatment of fatty oils, such, *e.g.*, as olive or almond oil, with dimethyl sulphate a diminution of the volume of the layer of dimethyl sulphate, as compared with the layer of the respective oil, is observed, whereas pinoline and oil of turpentine when shaken with an equal volume of dimethyl sulphate, cause an increase of volume of the latter, owing to solution of the substances named therein, to the extent of about 30 per cent [" Pinoline " is " German " or " Patent oil of turpentine " ; this J., 1898, 607.] The mixture obtained with pinoline has an orange colour, that with oil of turpentine is colourless but shows a considerable increase in temperature, a property, which it is thought might be applied with advantage to the determination of pinoline in oil of turpentine.—D. B.

ENGLISH PATENTS.

Kiln for the gasification or distillation of peat. M. Ziegler. Beuerberg, Germany. Eng. Pat. 18,174, Sept. 8, 1905.

THE kiln consists of a vertical shaft having one or more contractions extending all the way round ; the walls of the lower part of the shaft, in which the fire-grate and ash-pit are situated, being provided with numerous openings on all sides, both above and below the grate level, for the introduction of air. The kiln is always kept filled with peat, which is fed in from above through a hopper ; the gaseous products of the destructive distillation are led off at the top of the shaft ; whilst the residue is removed from the ash-pit by means of a screw conveyor. Preferably forced draught is used.—H. B.

Sulphate of ammonia ; Method of manufacturing ——. J. Grossmann, Manchester. Eng. Pat. 20,837, Oct. 14, 1905.

CRUDE ammonia liquor is distilled in the usual way, but without addition of lime, and the ammonia evolved is received in sulphuric acid in a saturator. The residual liquor in the still is concentrated, filtered, transferred to another still, and treated with an excess of sulphuric acid to expel, on heating, all the thiocyanic acid present, the

expulsion being aided by the injection of air. The ammonium sulphate solution thus obtained is then, after addition of sulphuric acid when necessary, used in the saturator to receive the ammonia evolved as first described. Or, the solution may be neutralised by ammonia and crystallised. When ferrocyanide is present in the crude ammonia liquor treated, the liquor may, at an intermediate stage of the process, be treated with an iron salt, and after removal of the precipitate formed, the cleared liquor is returned to the still in which thiocyanic acid is set free. If cyanide be present, an iron compound may be added to form ferrocyanide; or sulphur or a polysulphide is added to form a thiocyanate, with following treatment as described.—E. S.

United States Patents.

Wood-still. H. Copilovich, Hinckley, Minn., Assignor to Standard Turpentine Manufacturing Co., St. Paul, Minn. U.S. Pat. 814,901, March 13, 1906.

The metal still is cylindrical and has no bottom, but rests on the masonry foundation. There is an opening at the top for charging. The lighter products of distillation are led away by a pipe situated about halfway up the side of the still, and the tarry products are drawn off by a pipe running downwards from the floor.—C. E. F.

Coking; Process of ——. G. E. Merrill, Peace Dale, R.I. U.S. Pat. 815,453, March 20, 1906.

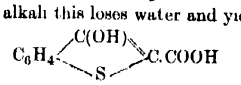
A horizontally moving layer of coal is subjected to successive degrees of heat, which may be regulated independently of each other, so that the different gases in the coal will be given off at determined points. The coal is, during its travel, protected from contact with the air. A spray of water plays on the heated mass of coal, and the steam generated thereby, together with any air which may be present, are removed by suction.—R. L.

German Patent.

Beech wood tar; Process for preparing an alkali-soluble product from —— which is solid at the ordinary temperature. Chem. Fabr. Flörsheim, Dr. H. Noerdlinger. Ger. Pat. 163,446, June 18, 1903.

Air, oxygen or ozonised air is blown through crude beech wood tar heated to 120°–150° C., until the product is soluble in alkalis. When cold, the product is brittle, and completely soluble in alkali; it is said to resemble colophony in many respects. It has only a feeble odour, and is stated to be applicable to pharmaceutical purposes, and also in the production of colour lakes. Metallic salts can be obtained in the usual manner from the alkali solution.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.



(*Continued from page* 310.)

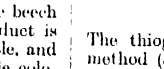
Indigo group; Sulphur-containing analogues of the ——. P. Friedländer. Ber., 1906, **39**, 1060—1066.

Thiosalicylic acid, obtained from *o*-thiocyanobenzoic acid and sodium sulphide, reacts readily and quantitatively with chloroacetic acid in presence of alkali, yielding phenylthioglycollic-*o*-carboxylic acid,

$C_6H_4(COOH)S.CH_2.COOH$, m. pt. 213° C. (uncorr.).

By the action of alkali this loses water and yields the acid

from which, on heating, carbon dioxide is disengaged, and *thioindoxyl* or *a-hydroxythionaphthene*



formed. The latter, when distilled with steam, is obtained in long colourless needles, melting at 71° C. On exposure to the air, thioindoxyl acquires a red colour, more rapidly in presence of alkali; and, on adding potassium ferricyanide to its solution in dilute caustic soda lye, red flocks of *thioindigo* separate,

Thioindigo sublimes in long needles and can be distilled in small quantities almost without decomposition. It is extremely resistant to oxidising agents, and is not acted upon by acids and alkalis, except fuming sulphuric acid, with which it yields a soluble red sulphonic acid. With alkaline reducing agents it yields a product soluble in alkalis, the solution of which, on exposure to air, becomes covered with a red bloom, and can be used for the dyeing of textile fibres, the shades produced being faster to light and oxidising agents than those yielded by indigo.

Thioindoxyl has properties quite analogous to those of indoxyl. With aromatic aldehydes, ketones and diketones, it yields "*thioindogenides*"; with isatin a *thioindirubin*; and with benzaldehyde and its derivatives, yellow crystalline compounds analogous to those obtained by Friedländer and Neudörfer (Ber., 1900, **80**, 1077; 1902, **32**, 1837) from ketocumaran, and erroneously believed to be flavone derivatives.

Arylthioglycollic acids to be used in the synthesis of thioindigo compounds, can be prepared from thioglycollic acid, $HS.CH_2.COOH$, from which by the action of aromatic diazo-compounds, products of the composition $X.N_2.S.CH_2.COOH$, are obtained, which on heating evolve nitrogen, with formation of the corresponding arylthioglycollic acids, $X.S.CH_2.COOH$. They can also be obtained in some cases by the action of nitro and halogen derivatives of aromatic compounds on thioglycollic acid in presence of alkali or an alkaline salt. For example, dinitrochlorobenzene and thioglycollic acid in presence of sodium acetate in alcoholic solution, yield *dinitrophenylthioglycollic acid*, $C_6H_3(NO_2)_2.S.CH_2.COOH$, m. pt. 167°–168° C., whilst *o*-nitrochlorobenzene or *o*-dinitrobenzene yields in a similar manner, in presence of potassium hydroxide, *o*-nitrophenylthioglycollic acid, $C_6H_4(NO_2).S.CH_2.COOH$, which, when reduced in acid solution, gives the inner anhydride of the amino-acid:

The thioglycollic acid is best prepared by Holmberg's method (*J. prakt. Chem.* [2], **71**, 264) from chloroacetic acid and potassium xanthate, the alkylxantho-acetic acid produced being decomposed by alkalis or ammonia.

The azo dyestuffs produced by the action of diazo compounds on thioindoxyl, give shades very similar to those produced by the *a*-naphthol-*o*-azo dyestuffs.—A. S.

Thiazines. R. Gnehm and F. Kaufler. Ber., 1906, **39**, 1016—1020.

The authors' experiments were made with the object of determining whether mercaptans and disulphides of the thiazine series possessed the characters of sulphide dyestuffs. As intermediate products, amino derivatives were prepared. By the action of alcoholic ammonia on Methylene Blue, one dimethylamino group is replaced by an amino group, an asymmetrical dimethylthionine being produced. Five grms. of Methylene Blue hydrochloride (free from zinc) were heated with 20—30 c.c. of a saturated alcoholic solution of ammonia for four hours in a sealed tube at 140°—150° C. The reaction product consisted of a brown crystalline mass, which, on opening the tube, rapidly turned blue. The pure compound was isolated, with suitable precautions to avoid contact with air, and was found to consist of the asymmetrical dimethylleucothionine:

The corresponding blue dyestuff, obtained by oxidation of the leuco compound in the air, is readily soluble in water, and moderately soluble in ethyl and methyl alcohols. On addition of alkali, the blue soution of the

dyestuff immediately turns red. By using benzylamine in place of ammonia, the reaction follows a different course, benzylaminotetramethylthionine being produced.

To prepare the mercaptan, Leuckardt's process (J. prakt. Chem., **41**, [2], 179; also this J., 1889, 187) was employed. Two grms. of dimethylthionine dissolved in 200 grms. of water were treated with 2·5 c.c. of concentrated hydrochloric acid and 0·5 grm. of sodium nitrite, dissolved in a small quantity of water, the mixture being cooled. After half-an-hour, a solution of 5 grms. of potassium xanthate in 300 c.c. of water was added and the mixture heated for four hours on the water-bath. The dark violet resin produced, consisting of the thiocarbonic acid ester of the thiazine-mercaptan, was filtered off, dried, and hydrolysed by sulphuric acid, when the thiazine-mercaptan was produced

$$R.S.CS.OC_2H_5 + H_2O = R.SH + COS + C_2H_5OH.$$

The authors have been unable to obtain the product in a pure state, but it possesses the characteristic properties of a sulphide dyestuff. It dissolves in sodium sulphide solution, with formation of a leuco-compound, and the solution dyes cotton a tolerably intense, somewhat dull blue, perfectly fast to washing.—A. S.

Methylene Green. R. Gnehm and E. Walder. Ber., 1906, **39**, 1020—1022.

By the action of nitrous acid on an acid solution of Methylene Blue, a bluish-green compound, Methylene Green, is formed, which has been generally regarded, although without any conclusive evidence, as nitro-Methylene Blue. The authors prepared the nitrate of Methylene Green by the action of sodium nitrite on a nitric acid solution of Methylene Blue. From the nitrate, the hydrobromide was obtained, and with this compound the amount of hydrogen taken up on reduction was determined. The results obtained prove that Methylene Green is the nitro derivative of Methylene Blue and not a nitroso compound.—A. S.

Dyestuff trade of Germany. For. Off. Ann. Series, No. 3544.

The export trade in dyestuffs continues to increase, the total shipments during 1905 exceeding those of 1904 by nearly 6000 tons; the total value of the exports during the last three years has been:—1903, £6,189,000; 1904, £6,255,650; 1905, £7,443,400. Of these totals, the exports of alizarin dyestuffs were valued at £754,550 in 1903, £741,950 in 1904, and £761,150 in 1905; and of Indigo, at £1,034,000 in 1903, £1,084,050 in 1904, and £1,384,450 in 1905.

The imports of dyestuffs into Germany were valued at £297,800 in 1903; £282,500 in 1904, and £309,350 in 1905. [T.R.]

Cyanines; Absorption and sensitising spectrum of the ——. A. von Hubl. XXI., page 393.

English Patents.

Colouring matters of the quinoline group [Cyanine dyestuffs]; Manufacture of blue —— and photographic surfaces sensitised therewith. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst a/Main, Germany. Eng. Pat. 16,227, Aug. 9, 1905.

Blue dyestuffs, which possess the property of rendering silver halide emulsions highly sensitive to red light rays, are obtained by the action of alkali on an alkyl halide of quinoline or quinaldine (or a mixture of these) in presence of formaldehyde, or a substance which easily generates formaldehyde. Twenty-five parts of quinoline-methyl chloride and 30 parts of *p*-toluquinaldine-ethyl iodide are dissolved in 500 parts of water, and boiled for a short time with 18 parts of 40 per cent. formaldehyde and 25 parts of a 16 per cent. sodium hydroxide solution. The dyestuffs are soluble in alcohol, and with difficulty in water. —T. F. B.

Moistening of substances [dyestuffs]; Process for facilitating the ——, and products made thereby. C. D. Abel, London. From Act. Ges. f. Anilinfabr., Berlin. Eng. Pat. 12,955, June 22, 1905.

The process is described in Fr. Pat. 353,440 of 1905 (this J., 1905, 1102). The products claimed are mixtures of (*a*) Indigo and soap, (*b*) Sulphur Yellow R Extra and soap, each of which is very easily moistened.—T. F. B.

Anthracene series; Manufacture of new compounds of the —— and of new colouring matters therefrom, and their application in dyeing and printing [Anthracene dyestuffs]. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 14,578, July 14, 1905.

See Fr. Pat. 357,239 of 1905; this J., 1906, 66.—T. F. B.

Methylanthraquinone; Manufacture of derivatives of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 16,632, Aug. 16, 1905.

β-Methylanthraquinone, or one of its negatively substituted derivatives, is converted by treatment with a halogen, into an ω-halogenated methylanthraquinone. The mono-, di- or tri-halogen derivatives may be obtained by using the necessary amount of halogen. The dihalogenated derivatives may be converted, by heating with concentrated sulphuric acid, with or without boric acid, into anthraquinone aldehydes.—T. F. B.

Dyestuffs; Manufacture of trisazo ——. R. B. Ransford, Upper Norwood. From L. Cassella und Co., Frankfort on the Maine, Germany. Eng. Pat. 14,787, July 18, 1905.

The dyestuffs prepared by combining diazo compounds with diammodiarylnaphthaldehydin-5-hydroxy-7-sulphonic acid (see U.S. Pat. 813,155 of 1906; this J., 1906, 260) are tetrazotised and combined with amines or phenols or their sulphonic acids. The resulting trisazo dyestuffs dye unmordanted cotton various bright shades of red, fast to washing and acids.—T. F. B.

Dyestuffs; Manufacture of Anthracene ——. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 18,196, Sept. 8, 1905.

See Addition of Sept. 7, 1905, to Fr. Pat. 343,608 of 1904; this J., 1906, 260.—T. F. B.

Dyes of the naphthalene series; Manufacture of o-oxymonoazo ——. W. and W. F. Kalle, Biebrich on Rhine, Germany. Eng. Pat. 23,034, Nov. 9, 1905. Under Int. Conv., Nov. 28, 1904.

The zinc salts of *o*-hydroxydiazonaphthalene compounds are readily formed by the action of a nitrite on the sulphonic acids of 1.2- or 2.1-aminonaphthol in presence of zinc oxide or zinc hydroxide, and zinc salts. These zinc compounds may be easily combined with resorcinol, dihydroxynaphthalenes, β-naphthol, naphtholsulphonic acids, &c.; the zinc compound of the *o*-hydroxyazo dyestuff is then decomposed by acid. Fifty-five kilos. of 1.2.4-aminonaphtholsulphonic acid are made into a paste with a solution of 60 kilos. of zinc sulphate in 70 kilos. of water, to which has been added 15 kilos. of 25 per cent. ammonia solution. A solution of 16 kilos. of sodium nitrite in 60 litres of water is then stirred in. Diazotisation is completed by heating for one to two hours at 40°—50° C. The product is neutralised by the addition of 60 kilos. of "calcined" soda, and mixed with a hot, saturated solution of 33·5 kilos. of β-naphthol. The combination is completed by heating, and the zinc lake is precipitated by addition of a solution of salt, and filtered. When boiled with dilute hydrochloric acid, the free acid is obtained, which dyes wool from an acid bath, bluish-red shades, converted by chroming into pure blue-black, and by treating with copper compounds into reddish-violet shades. (Compare Fr. Pat. 353,786 and U.S. Pat. 807,119 of 1905; this J., 1905, 1062 and 1906, 65.) —T. F. B.

French Patents.

Azo dyestuffs for wool; Production of ——. Soc. pour l'Ind. Chim. à Bale. Fr. Pat. 358,844, Jan. 3, 1905.

2.4-diamino-1-phenol is tetrazotised by means of a nitrite

in presence of a large excess of mineral acid, and preferably at a temperature below 0° C. A reddish-yellow solution of the corresponding tetrazo compound is so obtained and is combined with 1 mol. of an azo-component in acetic acid solution to form intermediate products. These intermediate products are then combined, in alkaline solution, with another mol., either of the same or of another azo-component to form dyestuffs of great fastness to fulling, light and washing, which vary in shade from Bordeaux red to violet. The shades produced are converted into violet-black to greenish-black shades by treatment with chromium salts, &c., on the fibre. For example, 10 kilos. of the hydrochloride of 2.4-diamino-1-phenol are dissolved in a little water and the solution cooled to −5° C., 25 kilos. of commercial hydrochloric acid are then added, and are followed gradually by a 10 per cent. solution of 7 kilos. of sodium nitrite. The solution of the tetrazo compound so produced is stable at ordinary temperatures. It is combined, in presence of an excess of sodium acetate, with 12·3 kilos. of the sodium salt of 1.4-naphthol-sulphonic acid. In a short time the formation of the red intermediate product is complete. This is then combined, either at once or after separation from the alkaline liquor by filtration, with 10 kilos. of sodium β-naphtholate in presence of excess of sodium carbonate in solution. It is best to gradually heat to 40° C. Finally, the whole is heated to 70°–80° C., and the finished dyestuff is salted out. It dyes wool from an acid bath in bright Bordeaux red shades, which are changed by subsequent chroming into violet-black shades, very fast to washing and to fulling. Dyestuffs with analogous properties are obtained if the 1.4-naphtholsulphonic acid is replaced by 1.5- or 2.6-naphtholsulphonic acids, and also if the β-naphthol is replaced by dihydroxynaphthalenes, such as 2.7-dihydroxynaphthalene.—E. F.

Dyestuff easily soluble in water, belonging to the naphthalene series; Production of an o-hydroxymonoazo ——. Fabr. de Coul. d'Aniline et d'Extraits ci-dev. J. R. Geigy. Fr. Pat. 359,310, Jan. 17, 1905.

SEE Eng. Pat. 1368 of 1905; this J., 1905, 1061.—T. F. B.

Dyestuffs, Process of making blue —— by oxidation on the fibre. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 359,637, Jan. 28, 1905.

SEE Eng. Pat. 406 of 1905; this J., 1905, 1010.—T. F. B.

Dyestuff of the triphenylmethane series; Production of new ——. Act. für Anilin-Fabr. Fr. Pat. 359,002, Oct. 30, 1905.

THE phenyl ether of *o*-aminophenol-*p*-sulphonic acid ("1-amino-2-phenylether-5-sulphonic acid") $C_6H_3(NH_2)(OC_6H_5)(SO_3H)$, is condensed with tetraethyldiaminodiphenylcarbinol. A second sulphonic acid group is introduced into the product; the amino-group is replaced by hydrogen and the disulphonated leuco-compound is then oxidised to the corresponding dyestuff. For example: 75 parts of tetraethyldiaminodiphenylcarbinol and 54·5 parts of the phenyl ether of *o*-aminophenol-*p*-sulphonic acid are dissolved in 500 parts of water and 32 parts of sulphuric acid of 66° B. The whole is then heated to 95°—100° C. for 24 hours. On cooling, the sulphate of the product of condensation separates in crystals which are filtered off, washed and dried. One hundred parts of this product are heated with 200 parts of 100 per cent. sulphuric acid to 60°—70° C., until a sample is completely soluble in water. The mass is then diluted with 300 to 400 parts of water and cooled. The greater part of the disulphonic acid separates on cooling. Seventy-nine parts of the sodium salt of the disulphonic acid, of 87·6 per cent. strength, are dissolved in a mixture of 20 parts of sulphuric acid of 66° B. and 180 parts of water, and are diazotised by means of a concentrated solution of 7 parts of sodium nitrite. To the solution of the diazo compound so obtained, 200 parts of alcohol and then about 3 parts of cuprous oxide are cautiously added with shaking. When all the nitrogen has been expelled, the alcohol is distilled off, the solution filtered, and oxidised with lead peroxide and sulphuric acid. By filtering from lead sulphate and drying, the dyestuff is isolated. It dyes unmordanted wool in greenish-blue shades from an acid bath. The dyeings are even, bright, and fast to alkalis.—E. F.

Aminonaphthols; Production of ——. F. Sachs. Fr. Pat. 359,064, Nov. 2, 1905. Under Int. Conv., Dec. 7, 1904.

AMINONAPHTHOLS are prepared by heating the corresponding naphtholsulphonic acids with sodium amide. In this way the sulphonic acid group is replaced by an amino group, and good yields of aminonaphthols are obtained. Diluents may be used. For example, an intimate, well-dried mixture of 2-naphthol-7-sulphonate of sodium, naphthalene and sodium amide is introduced into a vessel heated to 200°—230° C. and maintained at that temperature for one to two hours. The melt is then poured into water, the naphthalene distilled off in a current of steam, the residue neutralised and 2.7-aminonaphthol separated by filtration. In some cases molecular transformation takes place and the resulting aminonaphthol has not the amino-group in the same position, relatively to the hydroxyl group, as the sulphonic acid group in the original molecule. For example, 2-naphthol-6-sulphonic acid yields 2.5-aminonaphthol and 2-naphthol-8-sulphonic acid yields 2.5-aminonaphthol mixed with other isomeric compounds. E. F.

GERMAN PATENTS.

Nitroanthraquinonesulphonic acids; Process of preparing 1.5- and 1.8- — —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 164,203, Jan. 18, 1903.

BY nitrating anthraquinone-α-sulphonic acid, a mixture of 1.5- and 1.8-nitroanthraquinonesulphonic acids is obtained: it can be readily resolved into its components by reason of their different solubilities.—T. F. B.

Phenylglycin; Process of preparing ——. E. Lippmann. Ger. Pat. 163,515, June 9, 1903. XX., page 392.

1.3-Dialkylpyrogallol ethers; Process of preparing ——. Basler Chem. Fabr. Ger. Pat. 162,658, June 16, 1903. XX., page 393.

p-Acidylamino-o-aminophenols and their derivatives; Process of preparing ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 164,295, Aug. 6, 1903.

c p-DIAMINOPHENOL and its derivatives are converted into the corresponding *p*-acidylamino-*o*-aminophenols by treatment, in neutral or acid aqueous solution, with the calculated quantity of acidylating agent. The resulting derivatives, being *o*-aminophenols, are of value in the production of mordant dyestuffs.—T. F. B.

5-Nitro-1-benzaldehyde-2-sulphonic acid; Process of preparing —— from 5-nitro-2-chloro-1-benzaldehyde and alkali sulphite. Farbwerke vorm Meister, Lucius und Brüning. Ger. Pat. 165,613, Oct. 9, 1904.

2.5-CHLORONITROBENZALDEHYDE is converted into 5-nitrobenzaldehyde-2-sulphonic acid by heating it in anhydrous or aqueous alcoholic solution in presence of suspended alkali sulphite. The yield is said to be almost quantitative.—T. F. B.

α-β-Dinaphthazine; Process of preparing asymmetric ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 165,226, Nov. 10, 1904.

ASYMMETRIC α-β-dinaphthazine is obtained by melting β-naphthylamine with an alkali hydroxide: this method is superior to that in which bleaching powder is used, since, in the latter case, chloro-derivatives are formed. When nitrobenzene is added to the melt, no dinaphthazine is formed, but only α-β-naphthophenazine. The dinaphthazine can be converted in the usual manner into amino derivatives, which are of value for preparing azo dyestuffs: its hydroxy derivatives, prepared by sulphonation and melting with alkali, are also of value in the production of dyestuffs.—T. F. B.

Glyoxylic acid, its esters and amide, and phenylglycin and its derivatives. Process for preparing — — from oxalic acid and its derivatives by electrolytic reduction. Kinzlberger und Co. Ger. Pat. 163,842, Sept. 10, 1903. XX., page 392.

Dyestuff; Process of preparing a red sulphide — —. Kalle und Co., Act.-Ges. Ger. Pat. 165,007, April 19, 1904. Addition to Ger. Pat. 152,373, June 12, 1903. (See this J., 1905, 614.)

The hydroxyphenylhosindaline, prepared as described in Ger. Pat. 163,239 of 1904 (this J., 1906, 175), is utilised for the production of a sulphide dyestuff as described in the principal patent. The dyeings obtained with it on wool are more yellowish-red than those previously produced.—T. F. B.

Dyestuffs giving green shades after chroming, Process for preparing monoazo — —. Badische Anilin und Soda Fabrik. Ger. Pat. 164,989, July 27, 1904.

Sulphonic acids of *o*-diazophenols, or of 1.2- or 2.1-diazonaphthol or their derivatives are combined with 2-anthrol. The resulting dyestuffs give shades which are converted to fast bluish-green to yellowish-green on subsequent chroming.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 313.)

Paraphenylenediamine Brown on tissues; Production of, and resists for — —. H. Schmid. Bull. Soc. Ind. Mulhouse, 1905, **75**, 404–409.

The sole application in dyeing and tissue printing which the brown compound produced by the limited oxidation of *p*-phenylenediamine has as yet received, has been in conjunction with Aniline Black, in dyeing, the black resulting from the joint oxidation of a mixture of *p*-phenylenediamine and aniline, as Monnet (Ger. Pat. 4257 of 1886) discovered, showing no tendency to turn green on exposure to gaseous sulphur compounds. Attempts made to form the brown compound, by means of mixtures analogous to those employed in the production in dyeing and printing of Aniline Black, have invariably failed, owing on the one hand to the compound in question being prematurely generated in the dye-baths and printing mixtures, and on the other hand to the cotton tissues becoming injuriously acted upon by the mineral acid liberated. These drawbacks, it is now found, are overcome by neutralising a considerable portion of the acid of the diamine salt employed, or, better, by applying the diamine base in conjunction with ammonium chloride. In the latter case, the base acts on the ammonium salt in the steaming operation, liberating ammonia and forming with the acid the dihydrochloride of the base which, under the influence of an oxygen carrier, *e.g.*, ammonium metavanadate, reacts with the alkali chlorate also present in the mixture, thus yielding the brown compound. The tissues are padded in a solution containing, per litre, 16–20 grms. each of *p*-phenylenediamine, ammonium chloride and sodium chlorate, 1·5 grm. of "Rongalite C," and 0·015 grm. of ammonium metavanadate. White resists may be obtained upon the tissues which have been thus padded, and then carefully dried at a low temperature, by printing a mixture of Rongalite C (200 grms.) and gum thickening (800 grms.). Coloured effects are produced with mixtures similar to those employed in discharging Paranitraniline Red, or with colour-lakes fixable with albumin, in admixture with alkali sulphites, hydrosulphite- (hyposulphite-) formaldehyde compounds, &c. For direct printing, a mixture containing about 25 grms. of the diamine base per litre is made. The brown is developed by steaming the padded or printed tissues for a few minutes. The tissues may, however, be steamed for an hour or longer without injury. The brown produced is, it is stated, very fast.—E. B.

Diphenyl Black; Production of — — on tissues prepared with sodium β-naphtholate. M. Richard. Bull. Soc. Ind. Mulhouse, 1905, **75**, 411–414.

Tissues prepared with sodium β-naphtholate (by means of a solution containing, per litre, 17 grms. of β-naphthol, 19 grms. of caustic soda-lye at 36° B. and 8 grms. of ammonium ricinoleate) and dried in the "hot flue," are printed with diazotised *p*-nitraniline, &c., for red and other colours, and, for a black, with a mixture of "diphenyl oil" (45 grms.), aniline hydrochloride (45 grms.), lactic acid (45 grms), acetic acid (60 grms.), hydrochloric acid (12 c.c.), copper sulphide paste (15 grms.) mixed with water (20 c.c.), ammonium chloride (15 c.c. of a solution at 25° B.), sodium chlorate (35 grms.) dissolved in water (100 c.c.), the whole being reduced and thickened with starch paste (608 grms.). They are then steamed for one and a half minutes, passed through a bath of chalk or of tartar emetic and chalk, washed and soaped. Instead of a mixture of "diphenyl oil" and aniline hydrochloride, "diphenyl oil" or "diphenyl base" alone may be employed, the proportion of hydrochloric acid taken being modified. While, in order to produce Aniline Black on tissues prepared with sodium β-naphtholate, it is necessary to add to the printing mixture sufficient mineral acid to combine with both the aniline present in the mixture and the soda in the tissue, with the mixture of aniline salt and "diphenyl oil" recommended, a black is obtained, by the aid of less mineral acid than is required to combine with the "diphenyl oil." There is, therefore, no danger of tendering the fibre when this mixture is employed.

Stricker considers that the mixture for black described is likely to be of service in tissue printing, inasmuch as the method of development of the black is simple, the shade of the resulting colour is satisfactory, and the colours associated with the black are less tarnished by this than they are by the Logwood Black ("noir réduit") commonly employed.—E. B.

Naphthylamine Claret; Discharging — — with sodium hydrosulphite (hyposulphite), in the presence of caustic soda. L. Baumann and J. Frossard (of La Société E. Zundel). Bull. Soc. Ind. Mulhouse, **75** 1905, 421–424.

In a previous communication (this J., 1905, 435) a mixture was described which was capable of discharging Naphthylamine Claret, Betanaphthylamine Red, Orthonitrophenetidine Scarlet and other insoluble azo dyestuffs, when printed upon cotton tissues dyed with them, and steamed. A careful grinding of the printing mixture, which contained undissolved matters, was considered essential for its successful application. It has since been found that a similar mixture, containing sodium hydrosulphite, if not in solution, at least in such an extreme state of division that, without grinding, it exhibits no tendency to scratch the printing rollers, is obtained by using this compound when it is in a freshly precipitated and therefore relatively pure condition. A white discharge mixture is prepared, for example, by dissolving caustic soda (200 parts), in water (100 parts), adding glycerin (200 parts), and freshly precipitated sodium hydrosulphite, in the form of a pressed paste (500 parts), and, further adding, after four to six hours, thick gum solution (100 parts). The tissues printed with this are steamed for four to six minutes, then washed and soaped. Coloured discharges are obtained by admixing suitable dyestuffs with the white discharge mixture.—A *rose discharge*, with Cyanosine soluble in alcohol (50 parts), dissolved in phenol (150 parts), the solution being mixed with 800 parts of the white discharge printing-mixture; a *yellow discharge*, with Flavanthrene C in paste (150 parts) and 850 parts of the white discharge mixture; a *blue discharge*, from Phenocyanine V concentrated (40 parts), made into a paste with 60 parts of warm water and thus introduced into 900 parts of the white discharge mixture; blue discharges may also be obtained from Indigo, but this dyestuff does not give very satisfactory results, owing to the Indigo White in the mixtures rapidly becoming oxidised on exposure to air in the colour-boxes of the printing machine; *olive* discharges are produced from mixtures of the blue and yellow discharge mixtures. It is advantageous to add a little light petroleum

to the mixtures to prevent the formation of sodium carbonate in them from their direct contact with air. The discharges are produced by steaming for four minutes with very damp steam. After steaming, the tissues are passed through a 20 per cent. solution of an alkali bichromate, washed and soaped at 60°—70° C. Treatment with bleaching powder solution, to clear the whites, is unnecessary. The most important application of the process, it is stated, is in the discharging of tissues dyed with Naphthylamine Claret. For the effective discharge of this dyestuff it is pointed out that the tissues, after being prepared with β-naphthol, should not long remain undeveloped.—E. B.

Naphthylamine Claret; Discharging —— with sodium hydrosulphite, in the presence of neutral iron compounds. L. Baumann, G. Thesmar and A. Hug (of La Société E. Zundel). Bull. Soc. Ind. Mulhouse, **75**, 425—428.

Observing the relative facility with which azo dyestuffs containing nitro groups, *e.g.*, Paranitraniline Red and Paranitronaphthylamine Claret, can be discharged with sodium hydrosulphite-formaldehyde, the authors tried the effect upon the Naphthylamine Claret dyestuff of mixtures to which "nitro" compounds, such as *p*-nitraniline, nitrobenzene and sodium nitrite, were added. The last-named compound, in a neutral mixture and in the presence of an iron salt, was thus found to aid very powerfully the reduction of the dyestuffs in question. The presence in the printing-mixture of sodium ricinoleate and sodium citrate is further favourable to the action, the former of these salts probably neutralising the acidity of the iron salt employed and the latter preventing the precipitation of iron oxide upon the printed tissues. The presence of free alkali in the printing-mixture is injurious, as it causes the discharging power of the latter to be diminished. As the "catalytic" iron salt, ferric chloride is to be preferred to ferrous sulphate on account of its being more readily obtainable in a fairly pure condition than the latter salt. The two salts, however, employed in equivalent quantities, give almost identical results. A suitable printing-mixture is composed of a neutral starch-gum tragacanth paste (400 parts) in which sodium hydrosulphite-formaldehyde ("Rongalite C." 400 parts) is dissolved, and to which are added sodium ricinoleate (80 parts of a 50 per cent. solution), ferric citrate (120 parts of a solution prepared by dissolving together 16 parts of ferric chloride, 32 parts of sodium citrate, and 24 parts of glycerin, in 48 parts of hot water), and sodium nitrite (32 parts of a 40 per cent. solution). The discharge is produced on steaming for 3—4 minutes the tissues printed with this mixture. After steaming, the tissues are thoroughly washed and are then soured with either sulphuric or hydrochloric acid at 1° B., to which a little oxalic acid may be added. They are again washed and then soaped. A chlorinating operation to clear the whites is not needed. Exact determinations of the length of time during which the printing-mixture remains undecomposed have not been made, but it is stated that, provided it be neutral, the mixture appears to keep well. At the end of two days, it retains its full power of discharging. When the sodium nitrite, instead of being employed in the printing-mixtures, is applied to the tissues, in a preparation solution (see this J., 1906, 176), a solution containing 4 grms. of the salt per litre is used.

Besides discharging Naphthylamine Claret, the discharge mixture gives excellent discharges upon tissues dyed in Paranitraniline Red, Chloramsidine Pink, Orthonitrotoluidine Orange, Dianisidine Black and Chrysoidine Bronze. It yields imperfect discharges upon Benzidine Puce and Nitrophenetidine Scarlet.

Coloured discharges may be obtained by adding basic dyestuffs, dissolved in phenol, together with tannic acid, to the white discharge-mixture. Any iron left in the printed parts of the tissue, after steaming and souring, is removed by passing the tissues through a dilute, warm solution of oxalic acid. The dyestuffs of the Gallocyanine group, such as Modern Violet, may also be employed, without a mordant. Fast Black ("noir reduit"), a Logwood preparation, being capable of withstanding the necessary souring operations, may be printed, along with the white and coloured discharges.—E. B.

Naphthylamine Claret, Discharging —— with sodium hydrosulphite in the presence of other compounds. H. Schnud. Bull. Soc. Ind. Mulhouse, **75**, 1905, 429—432.

Baumann and Frossard (sealed note No. 1495, dated Sept. 23, 1904; see abstract above), in endeavouring to obtain an alkaline, discharge printing-mixture for Naphthylamine Claret, free from matters which scratch the surface of the printing rollers (see also this J., 1906, 176), have discovered that a mixture exempt from this defect is produced with sodium hydrosulphite, which has been manufactured and precipitated from solution immediately before use. As, however, most printworks are not in a position, like the Moscow works ("La Manufacture E. Zundel"), to make the hydrosulphite compounds they consume, the method described is not likely to be of general interest. On this account, the second process (sealed note No. 1543, dated June 20, 1905; see preceding abstract), due to Baumann, Thesmar and Hug, in which sodium hydrosulphite-formaldehyde ("Rongalite C"), a compound which is an article of commerce, is employed, will attract more attention. An important advantage of this second method is that it enables basic dyestuffs, such as the Methylene Blues, Nile Blues, Auramine, Thioflavine T, and the Phosphines, Rheonines and Rhodamines, as well as the dyestuffs of the Gallocyanine class, to be employed in the production of coloured discharges. With these dyestuffs, effects are obtained which, in point of brilliancy and fastness, rival those already produced upon grounds dyed in Paranitraniline Red.—E. B.

English Patents

Threads, Manufacture of artificial ——. R. Linkmeyer, Herford, Germany. Eng. Pat. 4755, March 7, 1905. Under Int. Conv., June 8, 1904.

A cupro-ammoniacal solution of cellulose is rendered suitable for the production of threads by the removal of a large part of the ammonia present.

This is effected either by injecting air into the solution or by shaking in contact with air. The process is assisted by subjecting the solution to the action of a vacuum.—A. B. S.

Cellulose threads; Manufacture of lustrous ——. R. Linkmeyer, Herford, Germany. Eng. Pat. 4765, March 7, 1905. Under Int. Conv., Oct. 17, 1904.

A cupro-ammoniacal solution of cellulose is discharged under pressure into a solution of soda- or potash-lye which precipitates the cellulose. The threads are then treated with air, water vapour or similar means to eliminate the free ammonia, and finally washed with a solution of sulphuric acid to remove the copper. A. B. S.

Wool-washing machines. G. W. and A. P. Tatterson, Stockton, U.S.A. Eng. Pat. 4779, March 7, 1905.

See Fr. Pat. 352,153 of 1905; this J., 1905, 1064.—T. F. B.

Textile fabrics; Machines for washing and scouring ——. J. S. Ainley, Kirkheaton, Yorks. Eng. Pat. 13,053, June 24, 1905.

Two, three or more series of rollers spaced at suitable distances apart are mounted in bearings above a tank, each series comprising three rollers arranged one above another. The fabric to be washed is passed between the middle and one of the outer rollers in each series, a length of the fabric being allowed to hang loosely between all the rollers so that it is immersed in the liquor in its passage

through the machine. After leaving the last series it is passed between the middle and second outer roller in each series, the fabric being divided into two or more "drafts" travelling in different paths, and when finally "dratted," the ends are fastened together to make an endless fabric, which can be passed through the machine backwards and forwards as frequently as desired. By this arrangement the material is alternately immersed in the wash liquor and then squeezed as it passes from one set of rollers to another, this action expediting the washing process and subjecting the fabric to the liquor whilst the latter is fresh and fully active, less soap being required than in the present washing machines.—D. B.

Textile fibres; Process of bleaching ——. H. Zeitschner, Helenabrunn, Germany. Eng. Pat. 5296, March 14, 1905.

THIS invention relates to a dry process of bleaching textile fibres, and consists in subjecting them to the action of chlorine or other bleaching agent in a gaseous form, the material being humidified to a slight extent by the admission of aqueous vapour prior to and during the bleaching process. It is then aired and subsequently treated with hydrogen gas in conjunction with moist air or water vapour, and is finally subjected to a wet treatment for the complete removal of the chlorine or other bleaching agent.—D. B.

Calico and similar fabric; [Waterproofing] Printing - . L. Frankenstein, J. W. Spencer, H. Spencer and C. L. C. Lane, Manchester. Eng. Pat. 9809, May 10, 1905.

THE colour is mixed with a solution of rubber thinned with naphtha to the desired consistency. This is printed on with engraved rollers or otherwise, and the solvent naphtha is driven off with heat. For bright colours the rubber is rendered white by addition of zinc oxide or a white pigment. (Reference is directed to Eng. Pats. 2719 of 1866, and 7725 of 1896.)—A. B. S.

Dyeing Vats. H. H. Lake, London. From J. Leontieff, St. Petersburg. Eng. Pat. 21,937, Oct. 27, 1905.

Woven fabrics; Filling the pores of - — *with pulverised substances.* J. Lohmann, Fahr, Germany. Eng. Pat. 23,911, Nov. 20, 1905.

A WEB of fabric, which has traversed a chamber containing the pulverised substance and preferably provided with apparatus for stirring the latter, is caused to travel past an adjustable pad or cushion, by which the powder on the fabric is uniformly distributed, the fabric being then passed between cylinders, which press the powder into the pores and also serve to impart movement to the web.—D. B.

UNITED STATES PATENTS.

Dyeing apparatus. E. Zillessen, Passaic, N.J. U.S. Pat. 813,478, Feb. 27, 1906.

THE apparatus consists of a number of superposed, open, relatively shallow dyeing trays through which the fabric is passed in succession with the aid of tension-rollers. There are arrangements for feeding dyeing materials into the trays, either into each tray independently, or in such a manner as to maintain a circulation of dye-liquor through the apparatus.—E. F.

Dyeing apparatus. E. Zillessen, Passaic, N.J. U.S. Pat. 813,479, Feb. 27, 1906.

THE arrangement described differs from that of U.S. Pat. 813,478 (see preceding abstract) merely in that two feed-pipes for supplying dye-liquor are attached to each tray, one on each side of the line of travel of the fabric. This arrangement is also claimed in the case where one tray only is used.—E. F.

Dye-Vat. F. I. Stone, Atlanta, Ga. U.S. Pat. 814,173, March 6, 1906.

THE vat consists of an outer casing, with a ring at the top, having an inwardly inclined flange, and an inner casing open at both ends and provided with a support for the contents, such as a loose bottom with detachable supporting cross bars. Steam can be discharged upwards between the two casings by means of a perforated steam pipe. There are also arrangements for supporting the inner casing within the outer one.—E. F.

Multicoloured dye effects in woollen fabrics, &c.; Process of producing ——. M. Becke, Höchst-on-the-Maine, Germany. U.S. Pat. 815,671, March 20, 1906.

THIS invention relates to the production of multicoloured effects in woollen and mixed fabrics. Animal hair is dyed with woollen dyestuffs fast to milling and acid, and is then treated with a tanning substance and a metallic salt, so as to render it dye-resistant. This material is then worked up with untreated fibre into spun goods or woven fabrics, and the latter dyed with ordinary wool acid dyestuffs in an acid bath. Goods or fabrics treated in this manner and dyed different colours are also claimed.
—B. N.

Fibrous material; Blue - - *and process of dyeing same.* V. Fussgänger, Assignor to Farbwerke vorm. Meister, Lucius und Bruning, Höchst on the Maine, Germany. U.S. Pat. 816,457, March 27, 1906.

SEE Eng. Pat. 406 of 1905; this J., 1905, 1011.—T. F. B.

Colours for printing on fabrics; Process of producing metallic or lustrous ——. L. Lilienfeld, Vienna. U.S. Pat. 815,600, March 20, 1906.

SEE Eng. Pat. 6645 of 1902; this J., 1903, 694.—T. F. B.

Steaming fabrics. Apparatus for ——. C. H. Fish, Dover, N.H. U.S. Pat. 814,124, March 6, 1906.

THE steaming chamber is adapted to contain steam under pressure. The fabric is led into, and withdrawn from the chamber by means of rollers, of which the centre one, which assists both in feeding in and withdrawing the fabric is covered with resilient material. The rollers are so packed that steam cannot escape.—E. F.

FRENCH PATENTS.

Silk; Treatment of artificial - - . Soc. Anon. Fabrique de Soie Artificielle de Tubize. Fr. Pat. 358,987, Jan. 7, 1905.

NITROCELLULOSE silk is spun directly on to bobbins, which are then placed in a closed vessel, with entrance and exit tubes for liquids. The alcohol is washed out with water and may be recovered by subsequent rectification. The nitrocellulose is then denitrified by suitable liquid reagents in the same apparatus. It is first treated with denitrifying liquids which have been already used for the same purpose, and have, therefore, become less effective: and then with successively fresher and stronger liquids, until finally freshly prepared denitrifying solutions are used. The denitrification can be performed in this manner in one hour. The denitrified fibre is washed with water and then bleached without removing from the apparatus. The fibre is subsequently washed and dried in the same apparatus, a current of air being used for the purpose. The advantages of the method are said to be:—Economy of time and of the liquids employed (since they are recovered and re-employed); also saving of alcohol, healthier conditions for workmen, production of a more regular and stronger product, economy of fibre, there being less mechanical manipulation, and almost complete prevention of danger of explosion or fire.—E. F.

Reeds and similar materials; Treatment of —— *for the production of textile fibres.* C. de Hatvany-Deutsch. Fr. Pat. 358,828, Oct. 24, 1905.

THE reeds or other material are treated with sodium hydroxide solution of 1 to 2 per cent. strength, at a temperature below 100° C. and preferably between 50°

and 80° C., the air being first removed by exposure either to a vacuum or to pressure. In this way, the material is thoroughly impregnated with the solution. The best results are obtained by first exhausting the air, then admitting the sodium hydroxide solution, exposing to pressure and heating. The residue is washed, the water removed by centrifugalising or otherwise, and the fibre dried. The yield of fibre is 30 to 40 per cent. of the raw material.—E. F.

Dyeing animal fibres; Method of ——. H. R. Vidal and G. E. Junius. Fr. Pat. 359,093, Jan. 10, 1905.

The sulphide black obtained by fusion of *p*-aminophenol, or of substituted diphenylamines derived from this product, with sulphur, differs from most sulphide dyestuffs by not being precipitated from its solution in alkali sulphide solutions by acetic acid, other organic acids or sodium bicarbonate. The solutions to which such reagents have been added are not greenish but bright yellow in colour. Such solutions, in which the alkalinity of the sulphides has been neutralised by acetic acid or sodium bicarbonate, dye wool in blue shades by oxidation in the air in the same manner as an indigo vat. The colour develops together with, and proportionally to, the oxidation. The method can also be applied to the dyeing of silk.—E. F.

Wool; Production of violet to blue shades on — fast to air. Fabr. de Coul. d'Aniline et d'Extraits ci-dev. J. R. Geigy. Fr. Pat. 359,600, Jan. 27, 1905.

See U.S. Pat. 794,315 and Eng. Pat. 1367 of 1905; this J., 1905, 841 and 965.—T. F. B.

Rinsing arrangement for dye-vats for piece goods. J. Leontieff. Fr. Pat. 358,895, Oct. 27, 1905.

Immediately after leaving the dye-vat the goods are led over rollers and through a pan fixed below the dye-vat and filled with water, or between sprinkling rollers, or through a combination of pan and sprinkling rollers. Instead of being filled with water, the pan may contain any solution used for after-treatment of the dyed fabric, and is fitted with heating devices, so that hot liquids may be employed.—E. F.

Dyeing and mercerising; Winding of cotton on bobbins for ——. P. Fontaine. Fr. Pat. 359,302, Nov. 10, 1905.

The cotton is wound on to a perforated tube, preferably conical in shape and made of a suitable metal. The larger end of this tube rests in a groove surrounding an opening connected with the liquid supply. A ring of felt is placed at each end of the tube in order to keep the cotton in place, and the whole arrangement is kept in position by means of a screw which passes through the centre of the tube, and is fitted with a nut which screws down on a metal plate at the small end of the bobbin.
—A. B. S.

Cotton bobbins; Process and apparatus for dyeing ——. P. Fontaine. Fr. Pat. 359,311, Nov. 10, 1905.

The apparatus consists of a cylindrical tank with a conical bottom. This tank is fitted with an air-tight cover, and the conical bottom portion is separated from the upper part by a diaphragm which is perforated with holes to carry the bobbin tubes. The upper and lower portions of the vessel are connected with the two pipes of a centrifugal pump so that the dye-liquor can be pumped through the holes in the diaphragm and so through the cotton on the bobbins. A valve is fitted to allow the air to escape on running in the dye-liquor, and there is a steam coil for heating the liquid round the bobbins.
—A. B. S.

Dyeing machine. P. Klug. Fr. Pat. 359,334, Nov. 11, 1905.

The material to be dyed is packed into vessels with perforated bottoms, which fit tightly one above the other. These vessels are placed in the dyeing tank, and can be quickly removed and be replaced by others at the end of each operation.—A. B. S.

Dyeings on fabrics; Production of fast ——. Badische Anilin und Soda Fabrik. Fr. Pat. 359,466, Nov. 15, 1905. Under Int. Conv., Oct. 30, 1905.

The dyestuffs of the Indanthrene class can be dyed as follows:—The cotton is padded with a mixture of one of the above colours with a suitable thickening agent and then dried. The treated material is then passed for half an hour, at 60°—65° C., through a jigger containing about 300 litres of water, 7·5 litres of caustic soda of 30° B., and 3 litres of a hydrosulphite solution prepared by mixing together:—3·3 kilos. of hydrosulphite B.A.S.F., 25 litres of water, and 1¾ litres of caustic soda of 30° B.

The material is rinsed and passed through a bath of weak sulphuric acid (2 c.c. per litre), rinsed again, and soaped at the boil.—A. B. S.

Velvet; Printing and embossing ——. F. Boyer. Fr. Pat. 359,164, Nov. 4, 1905.

A velvet with the pile lying down is printed by means of an engraved plate charged with the requisite colour; without removing the velvet from the press, a second engraved plate is applied to its back surface. The projecting portions of this plate are fitted with felt or similar substance and impregnated by contact with water thickened with starch or otherwise. By contact, the moisture passes into the velvet, and the pile thus softened becomes erect.—A. B. S.

Aldehyde derivatives; Production of — and their application as discharging agents. Badische Anilin und Soda Fabrik. Third Addition, dated Oct. 28, 1905, to Fr. Pat. 350,607, Jan. 7, 1905. Under Int. Conv., Aug. 18, 1905.

See Eng. Pat. 21,538 of 1905; this J., 1906, 15.—T. F. B.

Absorbents for gases or vapours and the application thereof for purifying or recovering gases or vapours, or like purposes; Improved ——. J. Dewar, Cambridge. Eng. Pat. 7808, April 12, 1905.

The claim is for the substitution of certain earthy oxides

for the charcoal used in the process described in Eng. Pat. 13,638 of 1904 (this J., 1905, 793), and for the absorption and recovery of gases or vapours by such oxides at ordinary or lower temperatures. The recovery of the absorbed gases or vapours from the oxide is effected by heating, extraction with suitable solvents, or by treating the oxide with some suitable agent to convert the vapour into another substance which may be subsequently recovered. The earthy oxides include those of aluminium, iron, chromium, thorium, magnesium and silicon, and the patentee states, as a guide for the proportions to be used, that he has found that 10 grms. of anhydrous substances, cooled to the temperature of boiling liquid air, will absorb the following volumes of air, measured at 0° C. and 760 mm. pressure:—Alumina, 1000 c.c.; silica, 400 c.c.; meerschaum, 600 c.c.; magnesia, 300 c.c.; iron oxide, 180 c.c.; thoria, 150 c.c. The most suitable temperature at which to use the oxides is said to be about −20° C.—W. H. C.

FRENCH PATENTS.

Sulphuric acid; Concentrating ——. A. Gaillard. Fr. Pat. 359,442, Nov. 14, 1905.

THE sulphuric acid to be concentrated is delivered into a pulveriser placed in the upper part of a tower constructed of acid-resisting material and cased with lead. A coke fire is maintained at the bottom of the tower, the heated air and gases from which, circulating up and down, mingle with the suspended acid particles, together with which they are drawn through a second (lead) tower, in which condensation of the concentrated acid takes place.—E. S.

Peroxides; Preparation and purification of ——. Soc. Anon. les Etablissements Poulenc Frères. Fr. Pat. 359,523, Jan. 24, 1905.

BARIUM peroxide, mixed with a little water, is added progressively to concentrated nitric acid contained in a vessel provided with a mechanical agitator, the temperature being maintained below 10° C., and the additions being continued until the acid is nearly neutralised. The crystals of barium nitrate that form are separated from the accompanying hydrogen peroxide. The latter is completely neutralised by baryta water, and then sodium phosphate solution, or a milk of barium phosphate is added until the precipitate formed ceases to be coloured by iron. The filtered liquid, still containing in solution barium nitrate, is distilled *in vacuo* to obtain hydrogen peroxide solution of over 50 vols. strength, the distillation being assisted by the introduction of a little steam. Pure zinc peroxide may be obtained by dissolving a salt of zinc in the solution thus produced (or in a more dilute solution) and precipitating by an alkali. The same process is available in obtaining other metallic peroxides.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 316.)

Glass; New method of making ——.

THE United States Vice-Consul at Nüremberg reports a new invention in the glass-plate industry. It is the invention of Mr. Fourcault, a Belgian, who has sold his patent to the European syndicate of plate-glass manufacturers for £190,400. This syndicate consists of German, French, and Belgian manufacturers, and one Bohemian factory. Hitherto, in the making of window glass the molten substance has been blown into cylinders by glass-makers' pipes, and subsequently flattened, while in the making of plate glass the viscid mass was cast from the pots and rolled. The new invention draws the molten substance from the pot and conducts it between rollers lying side by side. Seventeen pairs of these rollers are built up tower-like above the pot. The liquid mass cools on its way between the rows of rollers and comes out from them polished on both sides, in any desired thickness (this being regulated by the relative position of the rollers), beautifully flattened and ready for use. At present, dimensions of from 1 to 4 m. can be made. One early result is expected to be that the manufacturing of plate glass of 4 m. and less will undergo an entire change, as the making of glass plates will come chiefly within the scope of the plate-glass furnaces. [T.R.]

FRENCH PATENTS.

Ceramic industry; Mechanical washer for earthy materials for the — —. M. Roubaud. Fr. Pat. 359,549, Nov. 4, 1905.

THE washer described consists of a vat, the bottom of which is shaped thus:— ⌣⌣, in section. Two shafts are mounted longitudinally on the top of the vat, to each of which a toothed wheel is keyed; the wheels are of equal size and engage each other, one being driven by a pulley and belt. Straight or slightly-curved arms or paddles are fastened to the shafts, and spaced in such a way that the paddles on one shaft, as it rotates, pass between those on the other shaft. By the slow and regular movement of the paddles, all the light particles contained in the mixture are brought to the surface of the water during one-half of the period of rotation, and during the other half, enough time is allowed for the heavy particles to sink.—W. C. H.

Earthy body that can be cast [Slip] for artistic and industrial objects; Process for the preparation of an ——. C. Müller. Fr. Pat. 359,370, Nov. 11, 1905.

THE mass for the casting of various objects in moulds is composed of magnesia, chalk, ground minerals, magnesium chloride, &c., together with ammonia, which renders the mass gelatinous and prevents the deposition of the heavy particles in it, and the separation of a watery layer on the top or bottom.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 317.)

English Patent.

Loam, clay and the like; Machinery for preparing or treating ——. P. Baur, Brugg, Switzerland. Eng. Pat. 20,296, Oct. 7, 1905. Under Int. Conv., Dec 3, 1904.

The material to be worked is placed in the upper space between two adjacent cylinders revolving towards each other, and is thus pressed through holes in the walls of one or both cylinders into the interior, emerging by the ends, which are left open. The bearings of one cylinder are held and forced towards the other cylinder by means of springs, but are capable of sliding away from it, so as to allow any hard substances in the clay, such as stones, which cannot pass through the holes in the cylinder walls, to fall through between the two cylinders.—A. G. L.

United States Patents.

Wood; Method of preserving ——. J. B. Card, Chicago, Ill. U.S. Pat. 815,404, March 20, 1906.

The wood is placed in a closed receptacle filled with a mixture of liquids of different specific gravity, *e.g.*, a solution of zinc chloride and creosote. Pressure is applied to the receptacle and at the same time the liquids are caused to circulate through it, and, after the impregnation is finished, are forced out of the receptacle into a reservoir by means of air-pressure.—A. G. L.

Building material. C. M. Depew and H. E. McCoy Assignors to Pumice Stone Construction Co., all of San Francisco, Cal. U.S. Pat. 815,801, March 20, 1906.

The building material consists of a mixture of volcanic pumice of nut size and containing about 20 per cent. of alumina, besides silica, iron oxide and alkalis; scoria crushed to about the consistency of ordinary sand, containing about 27 per cent. of alumina, and which when ground is of dark colour, does not dust or powder, and has sharp edges and angular surfaces; and Portland cement.—A. G. L.

Cement; Manufacture of hydraulic ——, *and apparatus therefor.* B. Enright, Fordwick, Va. U.S. Pat. 815,080, March 13, 1906.

The process described consists in passing the highly-heated products of combustion and decomposition from a rotary clinker-forming cement kiln, through an incandescent charge of fuel and cement-producing material in a vertical kiln. By the partial or complete calcination of the material in the vertical kiln, the carbon dioxide issuing from the rotary kiln and that produced in the lower part of the vertical kiln are reduced to carbon monoxide, which is collected and utilised, and the cement-forming material obtained from the vertical kiln is also used. The contents of the vertical kiln are maintained at such a temperature and under such conditions that the reduction of the carbon dioxide can take place and at the same time the partial or complete calcination of the cement-forming material. As an alternative, a relatively small proportion of fuel may be employed in the vertical kiln, and the resulting gases, including those from the rotary kiln, may be passed through incandescent fuel to effect the reduction of the carbon dioxide. The chief components of the apparatus for carrying out the process are a rotary kiln, connected at its upper end with a separating chamber, which in turn is connected with the vertical kiln. Chambers containing coke or similar fuel are also connected with the separating chamber and with the vertical kiln, and means are provided for directing the products of combustion from the rotary kiln, or gases issuing from the vertical kiln, through either of the chambers containing fuel. The separating chamber is provided with an emergency stack, and steam and an air-blast can be supplied to the lower portion of the vertical kiln, from which means for carrying off the gases are provided. There are air-inlets into the vertical kiln, and absorbers connected with it and the air-inlets; and means are provided for passing the gases issuing from the vertical kiln, and also the air admitted to it, through the absorbers. The two kilns are separated by a damper, and a compartment, separated from the vertical kiln by doors, is arranged below the latter, as a receptacle for the calcined material from it. A ring with an inclined periphery is secured to the rotary kiln, and a similar ring attached to the separating chamber fits the former ring, to exclude air from the separating chamber.—W. C. H.

Cement; Apparatus for making ——. R. C. Carpenter, Ithaca, N.Y. U.S. Pat. 815,080, March 20, 1906.

See Eng. Pat. 4821 of 1903; this J., 1903, 951.—T. F. B.

Kiln; Rotary cement ——. H. Hitzel, Assignor to Alpha Portland Cement Co., both of Alpha, N.J. U.S. Pat. 815,705, March 20, 1906.

In combination with the rotary kiln there is arranged a hood with an air-chamber in it, a blower, a pipe leading from the hood-chamber into the blower, an exit-pipe leading from the blower through the hood into the kiln, and a pipe communicating with the blower and with a source of powdered fuel. Within this last pipe there is placed a rotary screw conveyor, the speed of which, as well as that of the blower, can be regulated so as to furnish either a uniform or varying quantity of fuel.—A. G. L.

French Patents.

Emery; Process for the manufacture of artificial ——. A. Gacon. Second Addition, dated Oct. 30, 1905, to Fr. Pat. 332,770, June 4, 1903. (See this J., 1903, 1294; and Eng. Pat. 23,492 of 1904; this J., 1905, 92.)

According to the present Addition to the original patent the bauxite employed in the manufacture of artificial emery is previously dehydrated. In order to economise the fuel required, the dehydration is effected by placing the bauxite above the materials that are being fused to produce the emery, with or without some separator. Further, the artificial emery produced is subjected to a second fusion, whereby the quality of the product is considerably improved. Waste chips, &c., obtained in the manufacture are also re-fused, either by returning them direct to the furnace, with fresh flux, or by making them into cakes together with useless emery dust, and treating these cakes alone in the fusing furnace, or mixing them with the fused emery before subjecting the mass to the second fusion. The waste is thus worked up again into useful emery blocks.—W. C. H.

Moulded bodies [of silicon carbide]; Process of making solid ——. Gebr. Siemens und Co. Fr. Pat. 359,260, Nov. 9, 1905.

See Eng. Pat. 21,347 of 1905; this J., 1906, 122.—T.F.B.

Wood; Process for the impregnation of ——. Act. Ges. für mechanische Holzbearbeitung A. M. Luther. Fr. Pat. 359,493, Nov. 16, 1905.

By this process the wood is impregnated with molten sulphur, and not with any substance dissolved in a menstruum, which has to evaporate, and thus tends to leave empty spaces. Wood is immersed in sulphur, heated to about 140° C., until the bubbling ceases, when the temperature is lowered to 110° C., and the wood gradually withdrawn from the sulphur. On cooling, the sulphur that has penetrated the pores, solidifies.—W. C H.

X.—METALLURGY.

(*Continued from page* 321.)

Lead and sulphur. K. Friedrich and A. Leroux. Metallurgie, 1905, **2**, 536—539. Chem. Centr., 1906, **1**, 1086—1087.

The authors have prepared a melting-point diagram for lead-sulphur alloys (obtained by fusing together pure lead and pure natural galena). The results, as also the microstructure of the solid products, show that the statement of Bredberg (Annalen, **9**, 274), as to the formation of the compounds, Pb_2S and Pb_4S, when lead and lead sulphide are fused together, is incorrect. The only compound of lead and sulphur formed in mixtures containing from 0·6 to 13·5 per cent of sulphur, is the sulphide, PbS, which begins to crystallise at 1103° C., whilst the eutectic mixture solidifies at about 327° C.—A. S.

Phosphorus; Influence of —— on the solubility of carbon in iron. F. Fettweis. Metallurgie, 1906, **3**, 60—62. Science Abstracts, 1906, **9A**, 174—175.

The author repeated Stead's experiments (this J., 1900, 1019), taking special precautions to ensure the saturation of the iron with carbon, and making re-determinations of the phosphorus in each alloy produced. He concludes from his results that Stead's alloys were not completely saturated with carbon. Alloys containing 15·8 per cent. of phosphorus, corresponding to the compound, Fe_3P, could not be obtained free from carbon, and it appears, therefore, that iron phosphide is capable of dissolving a small quantity of carbon. This view also affords a rational explanation of the proportions of carbon in other iron-phosphorus alloys.—A. S.

Copper matte; Roasting of ——, with utilisation of the furnace gases for the manufacture of sulphuric acid to be used in the extraction of copper from low-grade ores. A. Gmehling. Oesterr. Z. Berg. Hütt., 1906, **54**, 69—73, 88—90. Chem. Centr., 1906, **1**, 1060—1061.

Low-grade oxidised and mostly silicious copper ores containing, on the average, 2—5 per cent. of copper, are abundant in Chile. They are easily accessible, but have not hitherto been utilised, owing mainly to expensive freight charges. The author gives an account of the results obtained at a works erected at Guayacan, for the "Sociedad chilena de Fundiciones in Valparaiso" for the purpose of working up copper matte, with utilisation of the furnace gases. The matte contains 40—50 per cent. of copper, 22—27 of sulphur, and 23—30 of iron, and also, on the average, 150 grms. of silver and 5 grms. of gold per metric ton. It is roasted in muffle furnaces similar to those used for roasting zinc blende and pyritic ores. The roasted product is then mixed with silicious oxidised copper ores (containing not less than 6 per cent. of copper), rich slags and charcoal, and smelted in reverberatory furnaces to a crude copper of 97—98 per cent. purity. The furnace gases, after leaving the dust-chamber, are drawn through a lead tower, filled with coke, over which water or dilute sulphuric acid is caused to trickle. The acid wash takes up copper (0·25 to 1 grm. per litre), which, together with arsenic, is separated by treatment with a dilute solution of calcium sulphide. The washed gases are dried by sulphuric acid, heated in a system of horizontal wrought iron tubes and then passed into a contact-chamber for the manufacture of sulphuric acid by the Schroeder-Grillo process (Eng. Pats. 25,158 of 1898; 17,034 of 1900 and 10,412 of 1901; this J., 1899, 584; 1901, 579; 1902, 344). In the reaction chamber the temperature rises to 560° C. A yield of 90—96 per cent. of the theoretical amount of sulphur trioxide is obtained, and it is stated that in 24 hours, 2250 kilos. of commercial acid containing 93 to 96 per cent. of sulphuric acid can be obtained with 1 kilo. of contact material, with a consumption 0·75 kilo. of fuel per kilo. of acid.—A. S.

Copper and sulphur. E. Heyn and O. Bauer. Metallurgie, 1906, **3**, 73—86. Science Abstracts, 1906, **9A**, 176—177.

Copper and cuprous sulphide are not mutually soluble in all proportions, so that fused alloys of copper and sulphur at certain concentrations (*viz.*, with more than 9 per cent. of cuprous sulphide) form two layers, the lower one being richer in copper. No mixed crystals of copper and cuprous sulphide are formed, but there is an eutectic containing 3·82 per cent. of cuprous sulphide. Solid alloys containing less than this amount of cuprous sulphide consist of crystals of copper surrounded by the eutectic, whilst alloys richer in sulphide consist of crystals of the latter embedded in the eutectic. Sulphur dioxide alone does not attack copper at temperatures between 900° and 1100° C., but in presence of a reducing agent such as carbon or hydrogen, cuprous sulphide is formed. Cuprous sulphide at its melting-point cannot co-exist with cuprous oxide; the two compounds react with formation of copper and sulphur dioxide, until the supply of one is exhausted.—A. S.

Cadmium; Combustion of — —. W. Manchot. Ber., 1906, **39**, 1170—1171.

If a small blow-pipe flame be directed on to the surface of molten cadmium, and the products of combustion collected in a beaker, then, on introducing an acid solution of potassium iodide into the beaker, a blue coloration is produced, indicating the presence of a peroxide of cadmium.—A. S.

Antimony and antimony sulphide. Chrétien and Gumchant. Comptes rend., 1906, **142**, 709—711.

At all temperatures, from the fusion point to the boiling point of antimony sulphide, a mixture of the sulphide with metallic antimony separates into two layers—the upper, a solution of the metal in the sulphide, the lower, a solution of the sulphide in the metal. The proportion of metal in the upper layer increases with the temperature from 11·3 per cent. at 530° C., to 20 per cent. at 810° C. Above that, it increases very slowly to 21·9 per cent. at 1180° C. The composition of the solution at 810° C. corresponds nearly to the formula SbS. When cooled suddenly, from high temperatures, the alloys do not conduct electricity; but if cooled slowly, they do, in virtue of the separated metallic antimony.

The densities of the metal and the sulphide are given as follows:—

Metal.		Sulphide.	
°C.		°C	
13	6·75	13	4·63
898	6·55	643	3·85
1156	6·45	1116	3·82

The sulphide expands on melting by about 17 per cent. of its volume.—J. T. D.

Titanium; Distillation of — —. H. Moissan. Comptes rend., 1906, **142**, 673—677.

The author has succeeded in distilling titanium in the electric furnace (see this J., 1905, 1312, and 1906, 29 and 268), though its boiling point is higher than that of any of the metals of the iron group.—J. T. D.

Gold production of the World; Total ——. J. P. Hutchins. Eng. and Mining J., March 31, 1906.

The following table shows the total amount of gold produced by the principal auriferous countries of the world from the date of first recorded production to the end of 1905:—

United States	1792–1905	$2,860,854,000
Australasia	1851–1905	2,539,117,000
Russia and Siberia*	1814–1905	1,434,679,000
Colombia	1537–1905	895,735,000
Brazil	1691–1905	720,902,000
Africa	1887–1905	711,246,000
Mexico	1521–1905	307,161,000
Canada	1858–1905	237,202,000
Bolivia	1545–1905	199,011,000
Peru	1533–1905	119,389,000
British India	1884–1905	115,116,000
Austro-Hungary	1493–1905	70,242,000
Chile	1545–1905	33,266,000

* Russia 28 per cent., Siberia, 72 per cent.

[T.R.]

Japan; Mineral production of ——. Bd. of Trade J., April 12, 1906.

ACCORDING to official returns, the output of iron in Japan in 1905 amounted to 190,375 tons, as compared with 112,328 tons in 1904 and 36,515 tons in 1903. Other important items in the mineral production of Japan for 1905 are:—copper, 35,693 tons; coal, 11,581,755 tons; and kerosene oil, 42,945,600 galls. [T.R.]

New Caledonia; Mining industry of ——. For. Off. Ann. Series, No. 3548.

THE subjoined table shows the amount of ore exported during the last five years from New Caledonia:—

Year.	Quantity.		
	Nickel.	Chrome.	Cobalt.
	Tons.	Tons.	Tons.
1901	132,814	17,451	3,122
1902	129,365	10,281	7,512
1903	77,360	21,437	8,292
1904	98,655	42,197	8,964
1905	125,289	51,374	7,919

[T.R.]

Platinum production of the Urals. Bd. of Trade J., April 5, 1906.

THE Ural platinum yield in 1905 was as follows:—

Mineral Districts.	1904.	1905.
	Oz.	Oz.
South Ekaterinburg	180	1,492
South Verkhoturski	113,900	113,718
Perm	35,596	39,261

[T.R.]

Tin exports of the Federated Malay States. Bd. of Trade J., April 5, 1906.

THE following statement shows the weight of tin and tin ore (tin exported in the form of ore having been taken at 70 per cent. of the gross weight of the ore) exported from the Federated Malay States during the years 1904 and 1905:—

State.	1904.			1905.		
	Tin.	Tin exported in the form of ore.	Total.	Tin.	Tin exported in the form of ore.	Total.
	Pikuls.	Pikuls.	Pikuls.	Pikuls.	Pikuls.	Pikuls.
Perak	147,397	303,273	450,670	139,005	307,776	446,781
Selangor	120,151	184,550	304,701	114,686	175,181	289,867
Negri Sembilan	49,810	35,879	85,689	48,998	36,135	85,133
Pahang	5,687	22,381	28,068	5,600	29,279	34,879
Total	323,045	546,083	869,128	308,289	548,371	856,660

NOTE.—1 pikul = 133⅓ lb.

[T.R.]

Germany; Mineral Production of —— in 1905. Bd. of Trade J., April 5, 1906.

THE following table shows the quantity and value of minerals and salts produced in the years 1904 and 1905:—

——	1904.		1905.	
	Quantity.	Value.	Quantity.	Value.
	Metric tons.	Thousand marks.	Metric tons.	Thousand marks.
Iron ore	22,047,393	76,668	23,444,073	81,771
Zinc ore	715,728	39,479	731,281	47,839
Lead ore	164,440	14,706	152,725	15,346
Copper ore	798,214	21,731	793,488	23,500
Silver and gold ore	10,405	1,206	9,628	1,202
Cobalt, nickel and bismuth ores	14,016	930	10,848	891
Manganese ore	52,886	591	51,463	598
Pyrites	174,782	1,386	185,384	1,463
Asphalt	91,736	891	103,006	990
Petroleum	89,620	5,805	78,869	5,207
Rock-salt	1,079,868	5,013	1,165,473	5,494
Kainit	1,905,893	26,565	2,317,829	32,558
Other potash salts	2,179,471	22,294	2,725,654	28,056
Coal	120,815,503	1,033,861	121,298,167	1,050,089
Lignite	48,835,080	112,101	52,498,507	120,767

The products of reduction works are stated to be as follows:—

	1904.		1905.	
	Quantity.	Value.	Quantity.	Value.
	Metric tons.	Thousand marks.	Metric tons.	Thousand marks.
Copper ingots	30,264	36,305	31,717	44,611
Zinc	193,058	84,650	198,208	97,920
Lead, pigs, bars, &c.	137,580	32,546	152,590	41,049
Litharge	4,832	1,117	3,786	1,077
Pig-iron	10,058,273	520,736	10,875,061	578,724

The production of refined salt, and of various salts, in refined or commercial form, is shown in the following table:—

	1904.		1905.	
	Quantity.	Value.	Quantity.	Value.
	Metric tons.	Thousand marks.	Metric tons.	Thousand marks.
Salt	621,786	14,706	612,062	14,787
Potassium chloride	294,802	35,142	370,914	43,770
Magnesium chloride	25,730	539	29,017	532
Glauber salts	75,170	1,924	68,454	1,893
Potassium sulphate	43,959	6,994	47,994	7,512
Potassium magnesium sulphate	29,285	2,294	34,032	2,554
Magnesium sulphate	39,412	607	58,758	895
Sulphate of alumina	52,880	3,249	52,892	3,343

[T.R]

English Patents.

Washing and concentrating metalliferous, diamondiferous and other deposits and tailings from ore-crushing, Method and apparatus for ——. J. Hutchings, London. Eng. Pat. 6556, March 28, 1905.

After "sizing" by an elaborate system of trommels and hydraulic separators, the graded "assortments" are variously agitated or magnetically selected, the valuable products being delivered into locked receptacles. When the overflow contains fine float gold, it is forced through a mercurial trough by means of copper brushes and thus amalgamated.—J. H. C.

Steel; Process of hardening high-speed ——. S. N. Brayshaw, Manchester. Eng. Pat. 11,208, May 30, 1905.

The article is heated to a temperature short of scaling or deteriorating the surface, it is then "soaked" in a bath at 900° to 950° C. and finally quenched in a bath at 100° C. —J. H. C.

Rifle and gun barrels and other metallic surfaces; Treatment of —— for removal of fouling therefrom. King's Norton Metal Co., Ltd., T. A. Bayliss, and H. W. Brownsdon, London, and H. H. Smith, Abbey Wood, Kent. Eng. Pat. 13,297, June 28, 1905.

Metal surfaces "fouled" with copper or copper alloys are cleaned by the use of a solution prepared as follows:—Fifty c.c. of ammonia solution of 0·880 sp. gr. are diluted with an equal volume of water. In this is dissolved a tablet containing 5 grms. of ammonium persulphate and 1 grm. of ammonium carbonate.—J. H. C.

Ore concentration. H. L. Sulman, H. F. K. Picard and J. Ballot, London. Eng. Pat. 5260, March 13, 1905.

See Fr. Pat. 354,959 of 1905; this J., 1905, 1177.—T. F. B.

Zinc furnaces. E. Dor-Delattre, Budel, Holland. Eng. Pat. 19,655, Sept. 29, 1905.

See U.S. Pat. 806,121 of 1905; this J., 1906, 26.—T. F. B.

United States Patents.

Furnace; Continuous-heating ——. W. R. Miller, Assignor to Forter-Miller Eng. Co., Pittsburg, Pa. U.S. Pat. 815,198, March 13, 1906.

The claim is for a hollow track, resting on hollow supports which extend through the bottom of a continuous-heating furnace for billets. A cooling fluid is circulated through the hollow supports and/or the hollow track, and the former are further protected from the action of the heat by projecting screens.—W. H. C.

Filter [*Iron-hydrogen alloy*]. H. C. Gesner U.S. Pat. 815,417, March 20, 1906. I., page 362.

Insulator for electric apparatus [*Iron-hydrogen alloy*]. *Alloy of iron and hydrogen agglomerated in strong coherent bodies; Production of articles of an* ——. H. C. Gesner. U.S. Pat. 815,418 and 815,419, March 20, 1906. XI.A., page 380.

Precious metals; Refining hydrometallurgical products containing ——. C. W. Merrill, Alameda, Cal. U.S. Pat. 815,851, March 20, 1906.

Finely-divided "hydrometallurgical" products are mixed with litharge, and a soluble lead salt, and the litharge and lead salt are reduced to metallic lead by heating, further quantities of the lead compounds being added to the mixture as required. The resulting lead is cupelled to recover the precious metals.—A. S.

Precious metals from zinc ores; Extraction of ——. A. R. Meyer; E. J. Meyer, Executrix of A. R. Meyer, Assignor to the United Zinc and Chemical Co., Kansas City, Mo. U.S. Pat. 815,614, March 20, 1906.

An intimate mixture of the ground zinc ore and metallic copper is heated in order to vaporise the zinc and form a matte containing the copper and the precious metals. The matte is separated from the residue, and the zinc vapour is condensed.—A. S.

Nickel ores; Process of treating ——. C. Langer, Clydach. Assignor to The Mond Nickel Co., London. U.S. Pat. 815,717, March 20, 1906.

See Eng. Pat. 13,351 of 1905; this J., 1905, 1113.—T. F.B.

Ores; Process of treating ——. C. E. Baker and A. W. Burwell, Cleveland, Ohio. U.S. Pat. 816,061, March 27, 1906.

A pulverulent ore containing a metal or metals and a metalloid, for example, a sulphide ore, is treated with chlorine, the charge being abraded to continually expose

fresh ore surfaces to the chlorine. The metal (or metals) is converted into chloride, and the sulphur or other metalloid is recovered in the elemental state.—A. S.

French Patents.

Lead and silver; Process for the extraction of —— from their ores. Accumulatoren-Fabr. Akt.-Ges. Fr. Pat. 359,434, Nov. 14, 1905.

For the extraction of lead and silver from ores containing sulphides of iron and copper, the ores are introduced into a bath of a fused halogen salt, as zinc chloride, together with lead oxide or zinc oxide, and the lead and silver are then separated by addition of an electro-positive metal or by means of an electric current.—A. S.

Pig iron; Method of making foundry ——. C. Henning. Fr. Pat. 359,501, Nov. 16, 1905.

See Eng. Pat. 23,592 of 1905; this J., 1906, 319.—T. F. B.

Metals; Process of refining —— by means of metallic calcium. F. Brandenburg and A. Wiens. Fr. Pat. 359,592, Nov. 18, 1905.

The refining of metals by means of calcium has not proved successful up to the present, as, owing to the high temperature of the bath of molten metal, the calcium has been volatilised immediately it entered the bath and has thus exerted only a superficial action. In order to overcome this difficulty, the patentees propose to use the calcium in the form of shavings, and to mix these with shavings of other metals, more or less fusible than calcium, as may be required. For example, in the refining of copper, a mixture of shavings of calcium with those of copper, bronze, &c., is used, and for iron or steel, a mixture of shavings of calcium with those of iron or steel.—A. S.

Copper-nickel matte; Process of refining ——. N. V. Hybinette. Fr. Pat. 359,660, Nov. 21, 1905.

See U.S. Pat. 805,555 of 1905; this J., 1906, 26.—T. F. B.

Iridium; Process of producing metallic ——. H. C. Parker. Fr. Pat. 359,668, Nov. 21, 1905.

See U.S. Pat. 805,316 of 1905; this J., 1905, 1310.—T. F. B.

Slag; Apparatus for granulating ——. G. K. Hamfeldt. Fr. Pat. 359,326, Nov. 10, 1905.

See Eng. Pat. 22,032 of 1905; this J., 1906, 269.—T. F. B.

German Patent.

Cupriferous ores and metallurgical products; Process for the lixiviation of —— by means of ferrous chloride or ferrous sulphate solution, with the simultaneous introduction of air. O. Froelich. Ger. Pat. 163,409, Aug. 8, 1903.

A short pipe, open at both ends, is fixed in an upright position in the lixiviating tank, and inside this pipe a propeller is made to rapidly rotate, whereby a more effective circulation and more intimate contact between the air bubbles and the mixture of ore and solution, is caused. It is claimed that by this means the process is considerably shortened; with low-grade ores containing 3 per cent. of copper, it is stated that the extraction is frequently complete in the course of a few hours.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 323.)

(*A.*)—ELECTRO-CHEMISTRY.

Arsenic in wall-papers, fabrics, &c.; Note on the application of the electrolytic method to the determination of ——. T. E. Thorpe. XXIII., page 394.

English Patents.

Accumulators; Impts. in electric ——. H. Leitner, Woking, Surrey. Eng. Pat. 7720, April 11, 1905.

The plates are pasted with a mixture composed of lead oxide and sulphate or other salt of ammonium moistened with a saturated solution of the same salt, and the plates are afterwards heated to such a temperature as will decompose the solid ammonium salt. The liberation of ammonia leaves the plates extremely porous.—B. N.

Water; Apparatus for the purification of ——, by electrical means. J. F. Lester, New York. Eng. Pat. 18,427 Sept. 12, 1905.

The apparatus comprises a receiving chamber, an electrolytic chamber, an ozonising chamber, an upper chamber, a filter and a pure water receiving chamber, all contained within an outer casing. Water to be purified enters the receiving chamber which is situated at the bottom of the apparatus and on one side of an upright partition which, extending nearly to the top, divides the outer casing into two compartments. The water then passes through a porous partition and enters the electrolytic chamber, which consists of a box-like compartment fixed to the before-mentioned partition, and forming a segment with the circular casing. A supply of water fills this segment and keeps the electrolytic chamber cool. The latter is provided with electrodes. From this chamber the water passes upwards into the ozonising chamber and thence into an upper chamber extending across the top of the apparatus. On the other side of the partition is placed a series of filtering layers, and below these is the chamber for receiving the pure water after it has passed downwards through the filters. The various chambers, &c., may be cleansed as required by forcing water into them through pipes.—W. P. S.

Bleaching liquor; Electrodes for use in the manufacture of ——. R. Kother, Cunewalde, Germany. Eng. Pat. 21,437, Oct. 21, 1905.

The electrolytic vessel is divided into a number of compartments by means of vertical non-conducting partitions, and is made with an inclined bottom. Through each vertical partition extends a horizontal electrode, one-half of which in one cell acts as anode, the other half functioning as cathode in the next cell. In each cell the anode is below the cathode, which last is only just covered by the electrolyte, and is perforated so as to allow the hydrogen generated to escape readily. The electrodes may be of platinum or of carbon, which last for the anode halves is covered with an insulating material and with platinum sheet, foil or wire, the platinum and carbon being in electrical connection.—A. G. L.

Hydrogen peroxide; Producing —— [electrolytically.] G. Teichner, Nuremberg, Germany. Eng. Pat. 24,507, Nov. 27, 1905.

Persulphuric acid, or its sulphuric acid solution, is distilled, preferably *in vacuo*, and at a temperature exceeding 30° C. (care being taken to exclude catalytic agents), to obtain hydrogen peroxide. Or the hydrogen peroxide may be extracted by ether in a continuously working extracting apparatus. The solution thus freed from hydrogen peroxide is electrolysed with certain prescribed precautions, to reproduce the persulphuric acid, so that "the persulphuric acid will simply serve as a transmitter of oxygen and the peroxide of hydrogen will be obtained in uninterrupted circulating process by indirect oxidation of water." Percarbonates and perborates may be also used as sources of hydrogen peroxide, the peroxide being extracted by ether, and the solution again subjected to electrolysis.—E. S.

United States Patents.

Mercurial alkaline process. [*Electrolytic.*] W. E. Harmon, Mechanic Falls, Me., Assignor to American Electrolytic Co., Philadelphia, Pa. U.S. Pat. 814,692, March 13, 1906.

This invention relates to a method of increasing the efficiency of a mercurial alkaline process by the insertion

of pieces of carbon, or a small quantity of powdered carbon, in the amalgamating compartment, in contact with both the mercury and the electrolyte, the quantity of carbon being maintained fairly constant during the process. —B. N.

Furnace; Electric pressure ——. H. N. Potter, New Rochelle, N.Y., Assignor to G. Westinghouse, Pittsburg, Pa. U.S. Pat. 814,727, March 13, 1906.

An inner conducting tube of resistance material is adapted to contain the material to be heated, and is surrounded by refractory insulating material, an outer conducting tube in its turn surrounding both inner tube and refractory material, and forming chambers at each end by extending beyond the ends of the inner tube. Inlet tubes connect with one chamber, and an outlet tube with the other. The outer tube is made in sections, the latter being insulated from each other by ring-shaped "gaskets." The inner tube is provided with carbon terminals, which surround the ends, and the terminals are adapted to slide axially within the chamber, and to become suitably connected with the inner tube. A ring of asbestos, or other yielding material, separates the insulating material from the terminal connections of the inner tube, the asbestos being adapted to relieve the tendency of the insulating material to pack under the influence of the furnace heat. The carbon terminals are each in contact on opposite sides with metallic plates, and a cup-shaped strap connects each carbon terminal with the outer tube, means being provided for pressing the rim of the strap against the wall of the outer tube, and also for pressing the bottom portion of the strap between the carbon terminal and one or other of the metallic plates. Electrical connection is made between the ends of the inner and outer tubes, the ends of the latter being insulated from each other except through the inner tube, and forming the terminals of the furnace. Means are provided for modifying the pressure within the furnace.—B. N.

Purifying water by electrolysis; Apparatus for ——. H. C. Bailey, St. Louis, Mo., Assignor to Electra-Pura Water Co., New York. U.S. Pat. 814,764, March 13, 1906.

This invention relates to an apparatus for electrically treating water, and consists of a hollow casing or body composed of insulating material, which can be separated into two portions. In the upper and lower interior sides of the body are arranged spiral grooves, opposite to and in line with each other when the parts of the casing are placed together, and a pair of spiral metallic coils, which can be removed by separating the casing, fit into the grooves. The outer ends of the coils are secured to the outer casing, the inner terminals being near to the centre of the receptacle and adjacent to each other. The coils are so arranged as to form channels parallel to each other, so that water, under pressure, may flow in one direction towards the centre, the water then entering a secondary channel and flowing in a reverse direction towards the outer side without traversing the same channel more than once. One channel is provided with an inlet, and the other with an outlet; and an electrical circuit has its positive and negative terminals respectively connected to the coils. —B. N.

Vacuum lamps; Method of producing ——. D. M. Moore, Assignor to Moore Electrical Co. U.S. Pat. 814,794, March 13, 1906. II., page 365.

Electrolytic apparatus. F. McDonald, Roaring Spring, Pa. U.S. Pat. 814,864, March 13, 1906.

The electrolytic cell is provided with an anode compartment in connection with a tank for supplying a solution of brine, the tank being provided with a ball float, which is connected by levers with a valve in the supply pipe. The tank is connected by an overflow with a re-saturating tank, the latter being in turn connected with an overflow tank, from which the liquid is raised to an elevated tank by means of a pump. Means are provided for conducting the brine from the elevated tank to the valve. A gas-collecting pipe connects the cell to a series of vertical towers.—B. N.

Insulator for electric apparatus. H. C. Gesner, New York, N.Y. U.S. Pat. 815,418, March 20, 1906.

This invention relates to an electric insulator or high-resistance body composed of particles of an alloy of iron and hydrogen fritted into a coherent mass, or a mixture of this alloy with a material of higher specific resistance, such as fire-clay, may be used.—B. N.

Alloy of iron and hydrogen agglomerated in strong coherent bodies; Production of articles of ——. H. C. Gesner, New York, N.Y. U.S. Pat. 815,419, March 20, 1906.

The powdered alloy is moistened and compressed into a body, and then heated to a temperature sufficient to cause the component particles to frit or partially fuse together. Articles, compressed or agglomerated in this manner into strong coherent bodies, are also claimed. (See preceding abstract.)—B. N.

Water; Apparatus for decomposing —— by electrolysis. W. F. M. McCarty, Rocky Ridge, Md., Assignor to T. A. Darby, New York. U.S. Pat. 816,355, March 27, 1906.

The apparatus consists of two tanks connected together near the bottom by a conduit or pipe. In each tank an electrode of large superficial area, connected to a source of electricity, is suspended vertically. The electrodes are corrugated and perforated, and of spiral form, and the outer coil of each has a "radial discharge portion" projecting laterally and located directly opposite one end of the conduit.—A. S.

French Patent.

Electrolytic process. J. Hargreaves. Fr. Pat. 359,502, Nov. 16, 1905. Under Int. Conv., Nov. 22, 1904.

See Eng. Pat. 25,331 of 1904; this J., 1905, 1240.—T.F.B.

German Patent.

Glyoxylic acid, its esters and amide, and phenylglycin and its derivatives; Process for preparing —— from oxalic acid and its derivatives by electrolytic reduction. Kinzlberger und Co. Ger. Pat. 163,842, Sept. 10, 1903. XX., page 392.

(B.)—ELECTRO-METALLURGY.

English Patents.

Iron; Process and apparatus for the electrical production of cast ——. Soc. Electro-Metallurgique Française, Froges, France. Eng. Pat. 6468, March 27, 1905. Under Int. Conv., March 25, 1904.

See Fr. Pat. 341,611 of 1904; this J., 1904, 871.—T. F. B.

Electroplating vats; Impts. in ——. F. E. Bagnall, Coventry. Eng. Pat. 22,901, Nov. 8, 1905.

A vertical rotary shaft enters and extends nearly to the base of the electro-plating vat, and is rotated by mechanical means, the shaft having plates or blades arranged at angles to each other on a polygonal frame carried by the shaft. The plane of each blade is tangential to the shaft, the blades being connected to a source of electricity so as to form anodes, while at the same time they serve to effectively circulate and agitate the electrolyte. One vertical edge of each blade may project outwards beyond the carrying facet of the frame to which it is fixed —B. N.

United States Patents.

Electroplating apparatus. G. L. Meaker, Chicago, Ill. U.S. Pat. 815,027, March 13, 1906.

This invention relates to an electroplating apparatus

comprising a tank containing an electrolyte, an anode, a generator, and a tray for supporting the articles to be plated, the bottom of the tray being made of conducting material and acting as the cathode. Means are provided for giving a horizontal vibratory movement to the tray, the rearward motion being slow and the forward one rapid, the articles being thus advanced from one end of the tray to the other. The movement is produced by a cam, provided with "an abrupt shoulder," and a lever, which is acted upon by the cam, connected to the tray. The supporting surface of the latter has transverse shoulders, forming a ridged or corrugated surface, in order to effect the turning of the articles during their progressive movement.—B. N.

Furnace; Electric ——. M. Ruthenburg, Lockport, N.Y. U.S. Pat. 815,221, March 13, 1906.

This invention relates to an electric furnace in which a fused ferruginous bath is covered with a layer of inert material, such as bauxite slag, and with a layer of "comminuted coke resister" floated on the inert material. Several positive and negative terminals of an electric circuit are connected alternately to different regions of the resister.—B. N.

Etching of zinc by electrolysis; Process of deep ——. O. C. Strecker, Darmstadt, and H. H. Strecker, Mainz, Germany. U.S. Pat. 815,875, March 20, 1906.

See Eng. Pat. 21,322 of 1904; this J., 1905, 504.—T. F. B.

Ore-separator; Magnetic ——. R. R. Moffatt, Brooklyn, N.Y., Assignor to Imperial Ore Separator Co., New York. U.S. Pat. 816,491, March 27, 1906.

The apparatus comprises side frames supporting a magnet composed of two sets of opposed poles and two parallel cores, each core connecting one pole of one set in magnetic circuit with a pole of the other set. The poles of one set are nearer together than the poles of the other set, whereby two magnetic fields of different intensity are produced, and the poles of the same set are connected in magnetic circuit with each other by the side frames. A feed-conveyor passes through openings in the side frames, and "separating-conveyors" are also provided.—A. S.

Ores; [Electrical] Process for the reduction of —— C. P. Townsend, Washington, D.C., Assignor to E. A. Sperry, Brooklyn, N.Y. U.S. Pat. 815,881, March 20, 1906.

This invention relates to a method of reducing sulphide ores, such as galena, and consists in supporting or floating the ore upon a body of molten metal, which forms the base of the ore, under a fused electrolyte consisting of a haloid salt which is inert towards the ore. An electric current is passed to the ore as cathode from superposed anodes. The process of decomposing lead sulphide and separating lead electrolytically, by bringing the sulphide into contact with a cathode in a fused electrolyte of sodium chloride, the lead sulphide being practically insoluble in the latter, is also claimed.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 324.)

Cocoa-nut oil; Keeping qualities and causes of rancidity of ——. H. S. Walker. Philippine J. of Science, 1906, 1, 117—142.

The greater fertility of cocoa-nut trees near the seashore is attributed by the author to the soil being more porous than in inland regions and to being, as a rule, saturated with water at a depth of only a few feet from the surface. Chemical analysis showed little difference between soil from near the seashore and that from places further inland. As regards the effect of age upon the nut, it appeared from the average of a number of determinations that there was a slight increase in the proportion of kernel, copra, and oil in nuts that had been stored for a maximum of three months, but that afterwards there was a decided decrease. Green nuts contained only about half as much oil as nuts that were quite ripe, and the ripening process continued to some extent after cutting. The colour was found to have little, if any, influence on the composition of the nut. The quality of nuts from seashore trees was as good as that of nuts from inland trees, both yielding, on the average, the same proportion of oil.

The author, contrary to the commonly accepted belief, finds that pure cocoa-nut oil, properly prepared, is equal, if not superior, in keeping qualities to other fats and oils, and he attributes the fallacy to different observers not having procured fresh samples. The commercial product undoubtedly shows rapid deterioration, but this largely depends on the initial acidity of the oil. This acidity and its attendant bad taste and odour is developed in the copra itself, prior to the expression of the oil. Thus, in a sample cut up and exposed to moist air for a month, the acidity rose from 1·5 to 23·3 per cent. The active agents causing the hydrolysis of the fat in copra are moulds (principally *aspergilli*), either alone or in conjunction with certain bacteria, and the most suitable conditions for their development are a proportion of from 9 to 17 per cent. of moisture and a constant and moderately high temperature. A sample of copra containing 4·76 per cent. of water remained free from organisms, and no change in the acidity took place. On the other hand, several species of bacteria were found in copra containing 23 to 50 per cent. of water, but these had hardly affected the fatty portion and had formed very little free acid. No moulds were formed in these samples. Commercial copra usually contains from 9 to 12 per cent. of water, an amount favourable to the growth of moulds. It is advisable, therefore, to dry the copra, so that it shall not contain more than 5 per cent. of moisture, and to express the oil as soon as possible, whilst avoiding prolonged storage in a warm, damp atmosphere. Hot air apparatus, rotary or stationary, was found the most efficient means of drying copra, and it is suggested that hot-air drying might be used in conjunction with a centrifugal method, provided the by-product, "cocoa-nut cream," could be disposed of. Vacuum drying cannot be used effectively for cocoa-nuts from which the oil is to be expressed. Mould does not grow readily on pure cocoa-nut oil, but given a certain proportion of nutrient substance and of moisture, a growth may develop which will rapidly attack the oil. Thus, a sample of pure oil to which had been added 1 per cent. of "latic" (a coagulated residue, produced in the native process of making cocoa-nut oil, by boiling down an emulsion of fresh cocoa-nut kernel, and consisting chiefly of albumin and sugar), and 1 per cent. of water was exposed to the action of a mould in an incubator, and showed an increase in acidity of from 0·1 to 8·63 per cent. in a week. Direct oxidation by the action of air and light also plays a part in the deterioration of cocoa-nut oil, as of other fats, but this factor is of little importance in comparison with the changes due to mould action and can be prevented, to a large extent, by keeping the storage vessels as nearly full as possible.—C. A. M.

Cocoa-nut oil. J. J. Reijst. Pharm. Weekblad, 1906, **43**, 117—128, 151—163. Chem. Centr., 1906, **1**, 1061—1063.

In discussing the employment of cocoa-nut oil for the manufacture of soap, the author states that all fats can be saponified by the "cold process" provided the operation be carried out below the temperature at which the mixture separates into three layers, a lower one of lye, an upper one of melted fat and a middle layer of soap, but this can be done only if lye of a suitable concentration be employed. The separation into layers with rise of temperature is connected with changes of density, viscosity and capillarity. If the layers mix again to a homogeneous liquid on addition of water, this will be found to occur at the same concentration and temperature at which the soap dissolves. Potassium soaps can be "salted out" by using a soluble potassium compound such as potassium hydroxide or potassium carbonate.

For the examination of the fatty acids of cocoa-nut oil, the author used Heintz's method. An ethereal solution of the fat, cooled to 0° C., was saturated with bromine, the excess of the latter removed by sodium

thiosulphate, the ether distilled off, and the residue saponified with alcoholic alkali. The alcohol was then expelled, dilute sulphuric acid added, and the volatile acids distilled off with steam. The non-volatile acids were dissolved in dilute potassium hydroxide solution, the soap dissolved in water, and a quantity of silver nitrate, equivalent to considerably more than half of the bromine originally absorbed, was added. After boiling cautiously for half an hour, the mixture was acidified with hydrochloric acid, the layer of fatty acids dissolved in alcohol, the solution neutralised with ammonia and precipitated with magnesium acetate. The mixture was then treated with half its volume of hot water, cooled, the magnesium salts of the fatty acids separated, and in the filtrate, the dissolved hydroxy-acids liberated by acid, and freed from any adhering unsaturated acids by petroleum ether. The only unsaturated acid found by the author in cocoa-nut oil was oleic acid, whilst the highest member of the saturated acids was myristic acid; butyric acid was not present.

The constants found by the author for the glycerides of crude cocoa-nut oil and of various butter substitutes prepared from the same are given. For the detection of cocoa-nut oil in butter-fat, see this J., 1906, 324.—A. S.

Cod liver oils; American ——. L. M. Tolman. J. Amer. Chem. Soc., 1906, **28**, 388—395.

Samples of American and Norwegian cod-liver oils and other fish-liver oils, of known origin, were examined, the object being to ascertain whether pure American cod-liver oils conform to the requirements of the U.S.P., and also whether American oils differ materially from Norwegian oils. The results obtained show that, especially in the case of American oils, the composition and characters of the oils vary very considerably according to the condition of the fish, that is, according to the season at which the fish were caught. The variations in this respect are not so pronounced with Norwegian oils, as these are prepared from fish which are caught during a very short season and are thus in about the same condition. The oils were examined with regard to sp. gr., refractive index, iodine value and colour reactions with sulphuric and nitric acids. Only one of the American oils had a sp. gr. outside the allowed limits (0·918—0·922 at 25° C.), but this determination is of no value for indicating adulteration with other fish-liver oils. The iodine values of the American cod-liver oils varied over a wider range than is allowed in the U.S.P. With respect to the colour reactions, these were found to be not characteristic of cod-liver oil, but of fish-liver oils generally; besides, pure American oils frequently react differently from Norwegian oils, giving with nitric acid a purple colour changing to brownish-yellow, instead of rose-red changing to lemon-yellow. In the nitric acid test, the concentration of the acid has a marked influence on the colour produced. (See also this J., 1906, 272.)—A. S.

Sapindus rarak, Constituents of the fruit of ——. O. May. Arch. Pharm., 1906, **244**, 25—35.

The pericarp of the fruit of *Sapindus rarak* contains 13·5 per cent. of *sapindus-saponin*, $C_{16}H_{28}O_{10}$. The seeds yield 26·17 per cent. of a yellow non-drying oil, having the sp. gr. 0·911 at 15°C.; acid value, 5·3; ester value, 184·8; iodine value 65·08; Reichert-Meissl value 0·7; Hehner value 80·05. The fatty acids were composed mainly of oleic, with some stearic and palmitic acids.

—J. O. B.

Cholesterol; Reduction of ——. C. Neuberg. Ber., 1906, **39**, 1155—1158.

Ten grms. of purified cholesterol (from gall stones) were dissolved in 800—1000 c.c. of hot amyl alcohol, and the solution treated with 80 grms. of metallic sodium, more solvent being added when the liquid became turbid. After complete solution of the metal (five to seven hours), the liquid was diluted with water and rendered just acid by means of dilute sulphuric acid. The amyl alcohol layer was washed with water and distilled, and the oily residue, which frequently became crystalline under water, was purified by a single recrystallisation from dilute alcohol. If, however, it still remained oily, it was separated from the water and dried *in vacuo* over sulphuric acid and lime, the pale yellow syrupy residue dissolved in a little hot absolute alcohol, and the solution treated with water until it became turbid. The yield of crystalline product amounted to 30 to 50 per cent. of the original substance, and other oily products, not further examined, still remained in the mother liquor. The solid reduction product when purified by recrystallisation from alcohol, formed small white prismatic crystals melting at 119° to 124° C. Its elementary analysis agreed with that of dihydrocholesterol, $C_{27}H_{46}O$. It was readily soluble in chloroform, benzene, toluene, ether and ethyl acetate, less soluble in alcohol, methyl alcohol, and petroleum spirit, and insoluble in water. It gave the following reactions in the cholesterol tests:—(1) With Salkowski's reagent there was only a gradual slight reddening and fluorescence. (2) In Obermüller's test only a slight blue coloration appeared. (3) In the reaction with δ-methylfurfural the reduction compound, when present in small quantity gave only a yellow coloration with no absorption band, but with larger amounts there was the characteristic red coloration and the absorption band became visible. Unlike cholesterol it was dextro-rotatory, its reading $[\alpha]_D$, in ethereal solution being +18°·35 ($\alpha = 3°40'$; $l = 2$). In the author's opinion this dihydrocholesterol is probably identical with the naturally occurring coprosterol.

English Patents.

Fats and the like; Apparatus for the recovery of ——. C. Kremer and Ges. für Abwässer-Klärung, m.b.H., Berlin. Eng. Pat. 24,030, Nov. 21, 1905.

Claim is made for improvements in connection with the apparatus described in Eng. Pat. 14,461 of 1903 (this J., 1903, 1095). In order to prevent particles of fat escaping with the overflow, annular channels are placed between the fat-collecting vessel and the outlet. The baffles, formed by the channels, also produce an increase in the current, causing greater friction of the depositing solid particles, and thus promoting the separation of fat mechanically carried down by them.—C. A. M.

Lubricating oil. R. J. Crowley and F. F. Payne, London. Eng. Pat., 2680, Feb. 3, 1906.

Claim is made for a mixture of castor and olive oils, the latter being in the larger proportion, say, three to one. The mixture does not oxidise or deposit sediment.

—C. A. M.

German Patents.

Wool-fat; Process for decomposing —— into two portions, by one of which water is absorbed readily, and by the other with difficulty. J. Lifschütz. Ger. Pat. 163,254, Oct. 15, 1903.

See this J., 1905, 1242.—A. S.

Fatty preparations; Process for the manufacture of emulsifiable ——. Ges. zur Verwerth. der Bolegschen Wasserlöslichen Mineralöle u. Kohlenwasserstoffe, G.m.b.H. Ger. Pat. 163,387, Aug. 14, 1904.

Fatty preparations capable of forming permanent emulsions are prepared by agitating animal and vegetable oils, fats and waxes with the soluble rosin oils prepared according to Ger. Pat. 148,168 (see Eng. Pat. 12,349 of 1899; this J., 1900, 526) at a temperature of 60°—80° C. The products are suitable for the manufacture of pharmaceutical preparations, salves, lubricants, and finishes.

—A. S.

Fats; Process for the extraction of ——. A. Sachs. Ger. Pat., 163,057, Oct. 29, 1904.

The claim is for the use of liquefied carbon dioxide for the extraction of fats.—A. S.

Soap masses; Mould and cooling device for liquid —— in which the bottom is raised for the removal of the solidified soap block. Weber and Seeländer. Ger. Pat. 163,058, June 22, 1904.

The mould is provided with a movable bottom and is suspended from its centre of gravity. By rotation of a screw, gearing with a cog-wheel on the spindle by which the mould is suspended, the latter can be tipped over and the soap block delivered directly on to a table.—A. S.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*Continued from page* 326.)

(*A.*)—PIGMENTS, PAINTS.

English Patent.

Paint or composition; New anti-fouling ——. F. E. Dunnett, G. H. Nelson, and F. E. Nelson, London. Eng. Pats. 14,202, July 10, 1905, and 14,611, July 15, 1905.

The claim is for the utilisation of the final residuum (alkali sludge) obtained in the distillation or refining of petroleum as the essential ingredient of anti-fouling and non-corrosive compositions. For use as a paint, the "alkali sludge" or "petrolatum" is mixed with red lead or other suitable pigment in such proportions that the product may contain between 75 and 95 per cent. of the "petrolatum."—M. J. S.

French Patents.

Paint; Antiseptic and preservative —— for ships' bottoms and other submerged structures. G. G. Schobert. Fr. Pat. 359,488, Nov. 16 1905. Under Int. Conv., Nov. 17, 1904.

See Eng. Pat. 24,989 of 1904; this J., 1905, 142.—T. F. B.

Mica; Pulverisation of ——. F. R. Tiller. Fr. Pat. 359,312, Nov. 10, 1905.

Mica contained in a closed vessel (an iron cylinder for instance) is strongly heated for several hours, so that on cooling it may become opaque. The mica is then cut into strips, and is subjected in a closed vessel to the action of hot water, or of a heated vapour. The softened mica is then withdrawn, and after expulsion of the moisture, is ground to a fine powder, which is stated to be brilliant and silver-white.—E. S.

German Patent.

Beech wood tar; Process for preparing an alkali-soluble product from —— which is solid at the ordinary temperature. Chem. Fabr. Florsheim, Dr. H. Noerdlinger. Ger. Pat. 163,446, June 18, 1903. III., page 367.

Philippine wood oils. A. M. Clover. XX., page 389.

Spirit varnishes; Influence of resins on the decolorisation of —— by light. R. Namias. Monit. Scient., 1906, **20**, 265—266.

The coloured varnishes prepared by dissolving resins in alcohol and tinting with artificial colouring matters, are in many cases rapidly decolorised when the film which they leave on evaporation is exposed to air and sunlight. That this bleaching is due to some action exerted by the resin is shown by the fact that when the resin is absent, the decolorisation takes place much more slowly, and that different resins show differences in their influence, the smallest effect being produced by gum lac and myrrh, whilst elemi and mastic have the greatest.—M. J. S.

(*C.*)—INDIA RUBBER, Etc.

Rubber and rubber goods; Laboratory method of testing the durability of ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 628.

The method is based upon the assumption that the durability of rubber and of rubber goods, varies inversely as the ease with which they are oxidised by atmospheric oxygen, and so partially converted into resinous products of the nature of Spiller's resin (J. Chem. Soc., **3**, [2], 44), and of the bodies described by Herbst (this J., 1906, 224).

The sample to be examined is rolled into a thin sheet and dried to constant weight *in vacuo* over calcium chloride, or in a drying-oven at 100° C. 0·4 to 0·8 grm. of the dried sample are now sealed up in a thick-walled tube from which the air has been displaced by oxygen, and the tube is heated for 5 to 20 hours at 100° C. The tube is then allowed to cool, the rubber removed and rapidly weighed, and the increase in weight is taken as an inverse measure of the durability of the sample. The increase in weight shown by a sample of good rubber in five hours amounts to from 2 to 4 per cent.

In certain cases, samples of rubber-goods when tested in this way, show a decrease in weight (due to the oxidation of free sulphur to sulphur dioxide), followed by an increase. The author regards this decrease, too, as being a measure of the durability of the goods, since it is an indication of great porosity in them. Observations should be made of the decrease in tensile strength after oxidation, and taken into account in forming an idea of the durability of the goods, or rubber, examined.

A modification of the sealed-tube method is described in which the rubber sample is contained in a U-tube which is immersed in boiling water. The U-tube is connected with a reservoir containing oxygen, under moderate pressure only.—E. W. L.

Rubber Industry of French West Africa. For. Off. Ann. Series, No. 3543.

In February, 1905, an ordinance was published, applicable to the whole of French West Africa, consisting of five articles, whose object is to secure the following results:—(1) The suppression of adulteration of rubber, (2) the preservation of existing rubber plants; (3) the creation of new plantations; and (4) the creation of schools of instruction in the methods of cultivating and gathering rubber.

In the course of 1904 Sudan rubber fell rapidly in price owing chiefly to adulteration, but after the ordinance had been put in force, it rose again steadily, so that, during 1905, Sudan "twists" rose from 8 fr. 60 c. to 9 fr. 20 c., in January, to 9 fr. 60 c. to 10 fr. 20 c. in September. Sudan "niggers" also rose about a franc during that period.

The best French Guinea rubber, known as Conakry "niggers," continues to be exported in sacks bearing the customs seal as a guarantee of quality, but every other quality may be exported without it. The result of this compromise is that Conakry "niggers" have maintained their price. The application of the new regulations had a most marked effect in the Beyla district of Upper Guinea. The rubber produced there improved to such a degree that in April, 1905, it was given a special quotation on the Bordeaux market under the appellation of Beyla "niggers," and at once ranked with Conakry "niggers."

Because of its backward state, the new regulations are

not to be introduced into the Lower Ivory Coast until 1907; but they have been introduced into the upper districts which formerly belonged to the Sudan.

UNITED STATES PATENT.

Rubber and the like; Process for extracting —— from wood. A. V. de la Corte, San Luis Potosi, Mexico. U.S. Pat. 814,675, March 13, 1906.

CERTAIN classes of wood are broken to a suitable size and subjected to dry grinding, pressure and heat being applied during the grinding process, especially in the final stages. The particles of rubber agglomerate and are mechanically separated from the woody tissue.—C. E. F.

FRENCH PATENT.

Elastic material [Rubber substitute]; Manufacture of ——. L. C. G. Lesage. Fr. Pat. 359,183, Nov. 6, 1905.

THE material consists of a solution of gelatin in glycerin, to which is added formaldehyde or another coagulant, a solution of rubber or gutta-percha, and a vulcanising agent, and which is afterwards treated with a definite quantity of compressed air or other gas in a fine state of division. The mixing of the materials and the introduction of the air are effected in a special apparatus provided with a hollow shaft carrying hollow mixing blades, through which the air or gas under pressure is introduced. The mixing apparatus is jacketed. During the mixing a heating agent is circulated through the jacket and afterwards cold water, in order to rapidly cool the mass.—A. S.

Plastic masses from casein and the like; Process for the manufacture of ——. L. Collardon, Leipzig, Germany. Eng. Pat. 22,525, Nov. 3, 1905.

SEE Fr. Pat. 359,073 of 1905; this J., 1906, 327—T. F. B.

Glue; Manufacture of ——. C. W. Luther, Reval, Russia. Eng. Pat., 16,432, Aug. 12, 1905.

CLAIM is made for the manufacture of a glue, specially suitable for hygroscopic organic material such as wood, by treating an albumin, *e.g.*, defibrinated blood, with an alkaline-earth, preferably slaked lime, and water. The addition of a porous substance, such as wood meal, is advisable, and the separation of water from the glue may be prevented by the addition of a small proportion of a caustic alkali—not exceeding 1 per cent. of the weight of the albumin. The mixture is stirred for about 15 minutes until it begins to thicken, and is then allowed to stand until it forms a fairly hard jelly.—C. A. M.

GERMAN PATENT.

Glue-containing materials; Process for the separation of fat-solvents from ——. E. Bergmann and T. Berliner. Ger. Pat. 165,235, Oct. 24, 1903.

GLUE-CONTAINING materials from which the fat has been extracted by volatile solvents, are treated with cold water, without centrifugalising, for the purpose of removing the fat-solvent, and also blood and other impurities. The process allows of the extraction of the fat from "spetches," or glue-stuff (*Leimleder*), without the glue being also dissolved, as is the case in the usual method of removing the fat-solvent by means of steam.—A. S.

(*Continued from page* 327.)

Copper salts in irrigating waters. W. W. Skinner. J. Amer. Chem. Soc., 1906, **28**, 361—368.

THE author describes some experiments in connection with the injurious effect upon vegetation of copper salts, which as a waste product from the mining and reduction of copper ores, are frequently carried into and contaminate water supplies, which later on are used for irrigation purposes. In the wet method of concentrating low-grade copper ores, quantities of copper, up to 1·5 per cent., may remain in the tailings which are discharged on to the "dump" or directly into the stream, and thence upon the irrigated land. It has been shown that one part of copper per 700,000,000 is sufficient to retard the growth of wheat seedlings, whilst 1 part in about 800,000 is fatal to the growth of corn. In the author's opinion the presence of one part of copper per million should condemn water for irrigation purposes. It has been generally held that the presence of carbonates and bicarbonates renders the copper insoluble, but the author's experiments show that even in presence of considerable quantities of bicarbonates and carbonates, sufficient copper may remain in solution to be toxic to plants. The amounts of copper dissolved by different carbonate solutions are shown in the following table:—

Solution.	Parts of copper per million, in the solution.
Saturated solution of sodium bicarbonate ...	953·00
*Solution equivalent to soil containing 0·05 per cent. of sodium carbonate	1·70
*Solution equivalent to soil containing 0·025 per cent. of sodium carbonate	0·40
Solution containing 1·1075 grms. of calcium bicarbonate per litre	207·10

* These were sodium bicarbonate solutions of strengths corresponding to soil solutions, which would result from adding one-third of an acre-foot of irrigating water to soils containing the quantities of sodium carbonate indicated, assuming that the latter would be completely converted into bicarbonate.

Beetroots and beet juices; The "objectionable" [melassigenic] nitrogenous constituents of ——. K. Andrlik and J. Urban. Z. Zuckerind in Böhmen, 1906, **30**, 282—286.

In a former paper (this J., 1905, 808) the authors defined the nitrogenous constituents of beet juice which are not precipitated by cupric hydroxide in presence of alum, and which do not belong to the class of amides or ammonium compounds, as "objectionable" or melassigenic nitrogen. These injurious compounds are not removed from the juice by the usual process of triple saturation, nor by any of the processes to which the juice is subjected in the factory. In two beet-sugar factories there were found in the concentrated syrups, 96·3 and 94·9 per cent. of the "objectionable" nitrogenous constituents originally present in the beets themselves. The storage of beets, especially at a relatively high temperature, is accompanied by a disappearance of sugar by respiration and a progressive deterioration in the purity of the juice, *i.e.*, the ratio of sugar to non-removable non-sugar. This deterioration corresponds with an increase in the proportion of "objectionable" nitrogen in the juice, caused probably by a breaking down of the proteids of the beet during storage. The determination of this form of nitrogen, as prescribed by the authors, *loc. cit.*, can be made with a high degree of accuracy, and constitutes a very important criterion of value in the examination of beets and beet juices.—J. F. B.

United States Patent.

Starch; Apparatus for drying ——. E. E. Perkins, Melrose, Mass. U.S. Pat. 815,373, March 20, 1906.

The apparatus for the continuous drying of starch consists of an elongated closed chamber with an exit for the moist air at the top and an inclined floor with an exit for the dry starch at the bottom. A number of endless conveyors are arranged one above the other to carry the starch backwards and forwards through the length of the chamber on its way from the top to the bottom. A heater is provided beneath the floor through which hot air is delivered to one end of the apparatus; the air escapes at the top and enters an external cooling chamber in which the suspended moisture is condensed and separated, whilst the cooled dry air is returned through the heater. —J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

(*Continued from page* 331.)

Extract of malt; Conditions for increasing the —— to nearly the laboratory value. F. Cerny. Österr. Brauer- und Hopfen-Zeit., 1906, Nos. 1 and 2; Z. ges. Brauw., 1906, **29**, 202—203.

The brewery yield of extract from a malt may be increased to a value about 1—2 per cent. less than that found in the laboratory by improving the arrangement of the running-off vessel (Läuterbottich) and regulating the running-off and sparging. The best depth for the grains is 30—35 c.m. (12—14 in.). The false bottom should cover, as nearly as possible, the whole bottom of the tun and should be furnished with slits, not holes. The false bottom should be placed as low as possible and not more than about one-fifth inch from the bottom of the tun. The construction of the rakes is of importance for perfect extraction of the grains, and there should be a sufficient number of independent running-off pipes, each provided with a cock. The temperature at which mashing and running-off are begun—about 167° F.—should be maintained until the end of the sparging, during which the grains should be stirred up several times by the rakes. The outside mashing machine may be advantageously replaced by a pipe passing nearly to the bottom of the tun, "balling" being prevented by a rapidly-rotating propeller.—T. H. P.

Saccharification; Influence of composition of the water on ——. A. Fernbach. Ann. de la Brass, 1906, No. 5; Woch. f. Brau., 1906, **23**, 159—160.

The author discusses the influence of lime and magnesia salts in the brewing water, in the light of recent researches on the influence of the reaction of the medium on ferment action (this J., 1906, 192).

The earthy salts of the waters react with the alkali phosphates of the malt, and a portion of the phosphoric acid is precipitated. Although this double decomposition may not be of much consequence in the case of gypsum waters, it is of importance in the case of waters whose hardness is of the "temporary" character. The earthy carbonates of these waters neutralise the acid primary phosphates, and increase the alkalinity of the medium towards Methyl Orange. Maquenne and Roux have shown that the effect of adding acid to the medium, until it is nearly neutral to Methyl Orange, is to increase the diastatic activity and to increase the proportion of maltose formed as compared with the dextrin. Conversely the effect of waters with high temporary hardness is to lower the maltose: dextrin ratio and incidentally to darken the colour of the wort, owing to the increased alkalinity. The use of such waters is therefore indicated for the brewing of dark beers in which these effects are desirable, and the degree of their influence on the course of saccharification will be all the more marked the greater the weakening of the diastase by high curing. Hard waters of this type will have the same influence as increasing the temperature of mashing. Since the effect of alkalinity on the activity of the proteolytic enzyme closely resembles its effect on the diastase, it is very probable that the amide: albumose ratio of the wort would be affected in the same manner as the maltose: dextrin ratio. It is important, therefore, to ensure constancy of composition of the brewing water if the character of the beer is to be maintained.—J. F. B.

Brewery infection and pure yeast. R. L. Siau. J. Inst. Brewing, 1906, **12**, 118—134.

Before introducing a system of pure yeast fermentation into a brewery the most serious sources of infection must be investigated, and measures taken to minimise the danger. In the brewery in which the author's experiments were conducted, direct observation showed that the wort arriving on the cooler at a temperature of about 170° F., ran off it in a sterile condition until the temperature sank below 135° F. When, however, the cooler has run nearly empty and the temperature of the wort has sunk to about 120° F., it will be found that the later runnings are heavily infected. The author has found that a practically sterile wort may be passed from the cooler to the refrigerator by arranging that no wort enters the latter at a lower temperature than 130° F. This is done by allowing the first copper wort to run off the cooler until only about two barrels remain, the temperature having meanwhile fallen to about 140° F. The second copper wort is now admitted to the cooler at a temperature of 170° F., and thus effects a sterilisation of the residual first wort. The last two barrels of the second wort are similarly re-heated and sterilised by the spargings, the last two barrels of which may be run to waste. Briant (this J., 1904, 722) states that there is a danger of infection at temperatures on the cooler as high as 160°—170° F.

The prevention of infection on the refrigerator can only be effected by using a closed refrigerator supplied only with filtered air. With open refrigerators the infection can be reduced by protecting the beer as far as possible from aerial organisms and scrubbing out the channels after the passage of every brewing. Similar treatment can be applied to the wort pipes by passing a current of steam as frequently as possible. The author introduced a pure culture of yeast from a single cell into the brewery by gradual stages. Under ordinary conditions it was found necessary to renew the working stock by fresh pure cultures

every six to seven weeks. The beer was normally attenuated, took finings well, and possessed a remarkably clean flavour; after racking, it usually came into condition in two to three days. After the third week of storage the beers were quite flat, and failed to recover condition; single cell yeast is only recommended for beers which are to be drunk after a very short storage. For the first two or three weeks of storage, there is a slow fall in gravity of 2°—2·5° caused by the continued action of the culture yeast on the malto-dextrins which are fermented only with difficulty. At the end of that time the deposit of culture yeast appears starved and exhausted, and the gravity remains constant until, after about a fortnight, a visible development of wild yeasts is observed, accompanied by a further fall in gravity of about 1°. The question whether a noticeable after-fermentation is obtained when single-cell yeast is employed depends first on the relative proportion of slowly fermentable, complex malto-dextrins present in the wort, and secondly on the attenuative power of the yeast towards these bodies. These factors determine whether the yeast performs the whole of its work before racking, or whether a gradual loss of gravity continues in the early stages of storage.—J. F. B.

Wines; The "graisse" sickness [ropiness] of ——. E. Kayser and E. Manceau. Comptes rend., 1906, **142**, 725—727.

The authors have isolated and studied the micro-organism which causes ropiness in wines. It resembles the mannitol ferment in many respects, but is distinguished from the latter by the precipitate, without film, which it forms in culture media. The organism grows in chains of 0·7 -0·9 μ in diameter. With age, the chains become longer and felted together, and finally form a glutinous mass at the bottom of the liquid. The bacillus is somewhat anaërobic in habit and grows most rapidly at a temperature of about 30° C. It prefers highly nitrogenous media, peptones being the best nitrogenous nutrients and levulose the most favourable carbohydrate. From levulose, the products of fermentation consist mainly of mannitol, with smaller quantities of lactic and acetic acids, carbon dioxide and alcohol; traces of ammonia are formed, but no hydrogen. Dextrose is fermented less readily and yields no mannitol. Cane sugar is inverted and fermented, milk sugar is also attacked. Certain free acids, such as malic, tartaric and succinic acids, and especially citric acid, are highly inimical to the development of the bacillus; acetic acid has only a feeble influence. The bacillus can be acclimatised to the presence of antiseptics in wine. The degree of ropiness is proportional to the degree of suitability of the composition of the medium. The ropiness always disappears after the lapse of several months and the bacilli collect at the bottom; heating to 80° C. also destroys the ropiness. The bacilli are killed by heating at 50°—55° C. for 15 minutes. Certain wines of the Champagne district, especially those which undergo a slow, continued fermentation, are more susceptible to attack than others. The factors which influence susceptibility are: free acidity, organic nitrogenous substances, alcohol and potash salts.—J. F. B.

Wine imports into the United Kingdom. Parliamentary Paper, No. 88 of 1906 (Price ½d.).

According to this return, 10,871,229 galls. of wine were imported into the United Kingdom during 1905, from the following countries:—Spain, 3,062,112; Portugal, 2,943,571; Madeira, 43,892; France, 2,392,367; Germany, 426,366; Holland, 571,202; Italy, 253,417; Australasia, 861,902; other countries, 316,340 galls. Alcohol; Apparatus for recovering waste —— *from liquor casks and barrels.* T. H. Naughton, Boston, Mass., Assignor to Mary A. Naughton and M. Dunn, Springfield, Mass. U.S. Pat. 815,463, March 20, 1906.

A number of empty barrels are arranged end to end and are connected together in series by tubes carried by head-blocks and passing into the heads of the barrels through elastic, ring-shaped cushions. The first barrel of the series is connected with a steam supply and the last barrel with a condenser. The pipe leading from the last barrel to the condenser is provided with a steam injector.—J. F. B.

Alcohol; Process for recovering waste —— *from liquor casks and barrels.* T. H. Naughton, Boston, Mass., Assignor to Mary A. Naughton and M. Dunn, Springfield, Mass. U.S. Pat. 815,464, March 20, 1906.

Waste alcohol is recovered from a series of practically empty casks by injecting steam into the series of connected casks and drawing, by means of a short-circuited circulation, the contents of the barrels through the last barrel, vaporising the alcohol and condensing the vapours. (See preceding abstract.)—J. F. B.

French Patents.

Alcohol; Production of —— *from amylaceous matters saccharified by mucedinæ and fermented by yeast.* G. Jacquemin. Fr. Pat. 359,236, Jan. 14, 1905.

The apparatus comprises a series of closed vessels every part and fitting of which is capable of being sterilised by a current of steam, the various points of communication with the outside air being immersed in baths of antiseptic solution. The vessels are provided with mechanical stirrers, cooling and heating coils, escape pipes, trapped aseptically, for discharge of waste gases, pipes for filling and emptying and for the admission of sterilised air. The air supply is sterilised by passing through a combined chemical and mechanical air-filter and through a long worm which is frequently sterilised by steam, the condensed moisture serving to wash the filtered air. Saccharification of the liquefied starch is effected in the well-known manner by means of pure cultures of mucedinæ, and fermentation may either be conducted in the same vessels by pure cultures of yeast under aseptic conditions or may be effected in open tuns, after the addition of antiseptics, by yeast specially cultivated and acclimatised to resist antiseptics.—J. F. B.

Fermentation in three stages; Process of ——. J. T. and T. H. Board. Fr. Pat. 359,369, Nov. 11, 1905. Under Int. Conv., Dec. 6, 1904.

See Eng. Pat. 26,698 of 1904; this J., 1905, 1183.—T. F. B.

Acetifying apparatus working with stationary films of pure mycoderma and automatic feed. H. Frings, Jun. Fr. Pat. 359,115, Nov. 4, 1905.

The acetifying apparatus consists of a number of shallow tanks disposed one over another with air-tight joints. The uppermost tank is divided by zig-zag partitions, so as to form a surface condenser through which the fresh wort and the exhausted air are fed in contrary directions and cooled by water circulating inside the partitions. This water is then used for driving the fan for the air supply and finally for cooling the wort after sterilisation. The fresh wort from the condenser passes into a vessel in which it is used for cooling finished vinegar which has been sterilised by heat; the wort becomes hot and is sterilised. The interchange of heat between fresh wort and finished vinegar ensures their mutual sterilisation, the losses of heat being made good by heat from a boiler controlled automatically by a thermo-regulator.

A portion of the wort, whilst still hot, is withdrawn to a closed coke-tower into which the air intended for oxidation purposes is pumped. In this tower the air is heated and saturated with vapour, the warm air serving to maintain the temperature in the acetifying tanks whilst its state of saturation prevents evaporation in the latter. The cooled wort is fed into the acetifying tanks, in which films of pure-cultivated mycoderma have previously been formed, and the flow of wort at a constant level is maintained at such a rate that a single passage through the tanks suffices for complete acetification. The vinegar then goes to the heating apparatus whilst the exhausted air charged with vapours is caused to deposit these in the condenser before being discharged.—J. F. B.

Acetification; Apparatus for automatic ——. L. Royer. Fr. Pat. 359,413, Nov. 14, 1905. Under Int. Conv., Dec. 10, 1904.

Furnaces or apparatus for supplying heated air and gases for industrial purposes. [*Drying tea, &c.*]. P. D. G. Clark, Balangoda, Ceylon. Eng. Pat. 10,107, May 13, 1905.

The primary air to support the combustion of the fuel on the grate, *a*, enters, preferably under pressure, through the pipe, *b*, and the secondary air, also under pressure, enters through the pipes, *d*, *d*, and the jets, d^2, into the chambers, *c*, *c*, where it is heated by contact with the walls of the combustion chamber, A. The heated secondary air leaves the chambers, *c*, *c*, by the passages, c^1, c^1, and passes over the surface of the burning fuel. The openings, c^1, are made of different sizes so that the jets of heated air may mix more completely and the sum of the area of these openings is made small so that the air only leaves the chambers, *c*, *c*, slowly. The products of combustion pass upwards from the chamber, A, to the tube chamber, B, around the tubes, and through the ports h^1, in the dome, *h*, into the space, *l*, where they mix with another supply of warmed air, which enters the apparatus at *e*, passes down the channels, *f*, underneath the grate, *a*, and up the channels, f^1, into the space, *l*. The mixture of gases then passes through the tubes, *g*, g^1, is there further heated by the products of combustion from A, and collects in the space, *m*, from which it is conducted away to be used.—W. H. C.

Alimentary substance; Process for the preparation of an ——. A. de Sousa Reis, Oporto, Portugal. Eng. Pat. 21,946, Oct. 27, 1905.

Corn and its products; Process for bleaching and sterilising ——. O. Zimmermann, Ludwigshafen on Rhine, and C. H. Buchenau, Düsseldorf-Reisholz, Germany. Eng. Pat. 25,010, Dec. 2, 1905.

The corn is subjected for a short time to the action of a dilute solution (of from 1 to 5 per cent. strength) of sodium hyposulphite (hydrosulphite), or other salt of hyposulphurous (hydrosulphurous) acid. The bleached corn may be afterwards rinsed with water.—W. P. S.

United States Patent.

Bleaching and sterilising [*foods, &c.*]; [*Electrical*] *apparatus for* ——. S. Leetham, York, Assignor to The Ozonised Oxygen Co., Ltd., Manchester. U.S. Pat. 816,482, March 27, 1906.

See Eng. Pat. 5790 of 1904; this J., 1905, 341.—T.F.B.

French Patents.

Milk; Process for drying and preserving —— *in powder form.* P. F. Bévenot and E. de Neveu. Fr. Pat. 359,526, Jan. 24, 1905.

See Eng. Pat. 29,307 of 1904; this J., 1906, 36.—T.F.B.

Coffee extracts; Preparation of ——. H. Koerner. Fr. Pat. 359,263, Nov. 9, 1905.

For making an extract of roasted coffee the ground material is treated with volatile solvents, such as alcohol, ether, benzene, acetone or petroleum spirit, in order to extract the aromatic essential oil. The grains are then freed from solvent and extracted with boiling water until exhausted. The aqueous extract is evaporated and dried at 110° C., and is then powdered and thoroughly mixed with the essential oil extracted in the first operation. In the case of green coffee, the beans are ground and exhausted with boiling water, the extract being evaporated to dryness, roasted at a suitable temperature, re-dissolved in water and filtered. The residual grains are dried and roasted, and are then exhausted with volatile solvents for obtaining the aromatic oil. The residue from this treatment may be submitted to a second extraction with water, the combined aqueous extracts being evaporated to dryness, powdered and flavoured with the essential oil.
—J. F. B.

Coffee; Use of oxygen or ozone for maturing and improving ——. J. M. L. Desvignes. Fr. Pat. 359,451, Nov. 15, 1905.

Green coffee is matured and improved by treating it in a closed vessel with oxygen or ozone. The best results are obtained when the coffee has been rendered more porous by storage in a hot chamber immediately before treatment with the oxidising gas, and by exhausting the air from the closed vessel before admitting the oxygen. If desired the oxygen may be ozonised in the vessel itself whilst it is in contact with the coffee. Full maturation of the coffee can thus be effected in a few days.—J.F.B.

Fruits and vegetables containing sugar; Drying —— *and preparations of these materials.* J. R. Hatmaker. Fr. Pat. 359,689, Nov. 22, 1905. Under Int. Conv., Nov. 24, 1904.

See Eng. Pat. 25,563 of 1904; this J., 1905, 1249.—T.F.B.

(B.)—SANITATION; WATER PURIFICATION.

English Patents.

Sewage and other foul or impure waters; Apparatus for the purification of ——. W. O. Travis, Hampton, Middlesex. Eng. Pat. 4980, March 9, 1905.

The sewage, previously deprived of most of its suspended solids by treatment in a settling tank such as that described in Eng. Pat. 11,073 of 1903 (this J., 1904, 676), is subjected to bacterial treatment while passing at a suitable speed through tanks provided with sets of inclined plates of slate, stoneware, cement or the like. The fine suspended matters together with colloidal and other organic and inorganic substances are deposited on these plates and finally drop to the bottom of the tank, where they are further acted on by the bacteria. The sludge is afterwards periodically drawn off by means of suitable pipes which are provided at the bottom of the tank.—W. P. S.

Precipitation and decantation in the treatment of liquids [water]; Continuous ——. E. Declercq, Lille, France. Eng. Pat. 5332, March 14, 1905.

See Addition of March 7, 1905, to Fr. Pat. 348,375 of 1904; this J., 1905, 983.—T. F. B.

Oil in feed and other water; Impts. in and apparatus for determining the amount of ——. D. B. Morison. Eng. Pat. 8031, April 14, 1905. I., page 362.

Filtering of liquids [Water]; Impts. relating to the ——. A. McLean, London, and W. Paterson, Dumfries. Eng. Pat. 8565, April 20, 1905.

The claim is for the application of the filter for sewage described in Eng. Pat. 22,724 of 1904 (this J., 1905, 685) to the filtration of water for domestic and other purposes.
—W. H. C.

Water; Apparatus for the purification of —— *by electrical means.* J. F. Lester. Eng. Pat. 18,427, Sept. 12, 1905. XIA., page 379.

United States Patent.

Purifying water by electrolysis; Apparatus for ——. H. C. Bailey, Assignor to Electra-Pura Water Co. U.S. Pat. 814,764, March 13, 1906. XI., page 380.

French Patent.

Water; Process and apparatus for the purification of ——. J. F. Wixford. Fr. Pat. 358,991, Sept. 22, 1905. Under Int. Conv., Sept. 23, 1904.

The water is pumped from a river or similar source and delivered into two separate wells. In these wells the water receives the addition of predetermined quantities of ferrous sulphate and lime solutions from tanks which contain these chemicals. The tanks are supplied with water, the supply to the lime tank being heated. The treated water is then led from the wells by pipes which empty into a conduit leading to a settling tank. Ferrous fluoride may be employed in place of ferrous sulphate and the supply of lime must be sufficient to render the water distinctly alkaline. (See also U.S. Pats. 807,008 and 807,412 of 1905; this J., 1906, 86—87.)—W. P. S.

(C.)—DISINFECTANTS.

English Patent.

Disinfection of premises, articles and such like; Process and apparatus for the ——. P. Lassablière, Paris. Eng. Pat. 25,072, Dec. 2, 1905. Under Int. Conv., Dec. 3, 1904.

The apparatus has for its object the complete conversion of trioxymethylene into formaldehyde and consists of a pressure-chamber closed by a lid secured by bolts. The lid carries a pressure-gauge, a safety-valve, a tapped opening for introducing the disinfecting products, and an outlet pipe for the formaldehyde vapour. This pipe is provided with a screw-down needle-valve and a spring-valve which, even when the needle-valve is opened, only allows the gas to escape when the pressure in the chamber is more than 3 kilos. (per sq. cm.). Means are provided for heating the pressure-chamber, and amyl, methyl, or ethyl alcohol, &c., may be added to the trioxymethylene in order to prevent the discharge of any of the latter in an unconverted condition.—W. P. S.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page* 334.)

Celluloses [Beetroot and ramie]; Nature of certain ——. A. Ernest. Z. Zuckerind. in Böhmen, 1906, **30**, 279—282.

Exhausted beetroot slices and ramie fibres were treated alternately with hot, concentrated baryta water and 4 per cent. hydrochloric acid until residues of practically pure celluloses were obtained. The celluloses were then dissolved in a liquid composed of 250 grms. of concentrated sulphuric acid and 84 grms. of water per 100 grms. of cellulose. The products were diluted, hydrolysed by heating at 95°—97° C., and neutralised by strontium hydrate. The solutions were concentrated, the dextrinous components were precipitated by alcohol and the filtered liquids were evaporated to syrups, the yield of syrup being, however, relatively small. In both cases, the syrups obtained appeared to contain nothing but dextrose, whence it is concluded that both the celluloses investigated belong to the class of dextroso-celluloses. The beet cellulose differed from the more normal type of ramie cellulose, in that it showed a greater tendency to the formation of humus substances during hydrolysis.
—J. F. B.

Arsenic in wall-papers, fabrics, &c.; Note on the application of the electrolytic method to the determination of ——. T. E. Thorpe. XXIII., page 394.

English Patents.

Threads; Manufacture of artificial ——. R. Linkmeyer. Eng. Pat. 4755, March 7, 1905. V., page 371.

Cellulose threads; Manufacture of lustrous ——. R. Linkmeyer. Eng. Pat. 4765, March 7, 1905. V., page 371.

United States Patents.

Paper making machines; Apparatus for supplying colouring material in —— *for the manufacture of one side coloured, clouded-coloured and marbled papers.* C. Tittel, Josefsthal, Austria-Hungary. U.S. Pat. 815,763, March 20, 1906.

See Eng. Pat. 17,163 of 1905; this J., 1906, 87.—T. F. B.

Paper making machine. C. Tittel, Josefsthal, Austria-Hungary, U.S. Pat. 816,402, March 27, 1906.

See Eng. Pat. 10,798 of 1904; this J., 1904, 834.—T. F. B.

French Patents.

Peat half-stuff [Paper manufacture]; Process and apparatus for manufacture of ——. A. Kirner. First Addition, dated Oct. 24, 1905, to Fr. Pat. 353,538, April 17, 1905 (this J., 1905, 1028).

The roller-mills in which the peat is reduced to pulp are improved by imparting to each of the rolls a movement in the horizontal plane along the axis, in addition to the rotary motion. This axial motion may be in contrary directions for the two rolls of a mill, or may be in the same direction at different speeds.—J. F. B.

Paper-pulp from graminaceous plants, and more especially from esparto, diss and the dwarf palm; Manufacture of ——. L. Echégut. Fr. Pat. 359,550, Nov. 6, 1905.

The plants are crushed between rollers, chopped into suitable lengths, and then boiled for a short time with

a solution of sodium carbonate. The liquor is drained off and the material washed in the boiler; the washed material is then treated with a solution containing 2—6 per cent. of sodium nitrate and 7—10 per cent. of sulphuric acid, with which it is boiled for several hours. When the fibre has become thoroughly loosened by this treatment, it is drained, washed and bleached.—J. F. B.

Fibres; Process of bleaching natural —— for paper-making. A. Jouve. Fr. Pat. 359,452, Nov. 10, 1905.

Natural fibres are treated either hot or cold with an alkaline solution; the pulp is then washed and "soured," and is bleached by treating it with a 2—5 per cent. solution of a manganate or permanganate, which is added to the pulp in small quantities at a time until the action is complete. Finally the pulp is washed and treated with sulphurous acid or a solution of a sulphite or "hyposulphite." It is stated that the addition of a little hypochlorite to the manganate solution economises the latter, and confines its action to the colouring matters, thus protecting the cellulose from being attacked by the oxidising agent.
—J. F. B.

Paper making machine. H. Parker. Fr. Pat. 359,297, Nov. 10, 1905. Under Int. Conv., April 17, 1905.

See U.S. Pat. 808,614 of 1905; this J., 1906, 88.—T. F. B.

Paper; Manufacture of [couching and drying] ——. E. Armengaud, sen. Fr. Pat. 359,419, Jan. 21, 1905.

The paper is couched underneath the machine on the return journey of the making-wire. The web is transferred to an endless wire-band which carries it over the drying cylinders, the transference being effected by the pressure of a perforated upper couch-roll against a solid lower couch-roll which is surrounded by a short endless felt. The web of paper on the wire-band then travels a short distance until a second draining felt engages the compound band, so that the wire lies between the paper on the outer side and the felt on the inner side. This felt is continuously dried, during its passage, by pressure between a pair of rollers, and it passes, with the paper and wire, over a portion of the first drying cylinder. Just before this is reached, however, the compound band passes over a suction-box, the felt being protected from friction by a short endless wire band which supports it over the suction-box.—J. F. B.

Fuel; Agglomeration of ——. [Utilisation of waste cellulose lyes]. A. E. Tavernier and C. Oulman. Fr. Pat. 359,249, Nov. 8, 1905. II., page 365.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

Lithium theobromine, a soluble derivative of theobromine. E. Dumesnil. J. Pharm. Chim., 1906, **23**, 326—328.

Lithium theobromine is prepared by adding an excess of theobromine to a solution of lithium hydroxide. The liquid is filtered and evaporated, and the residue dried at 110° C. in a vacuum. The amount of lithium found in the product corresponds to the formula, $C_7H_7N_4O_2Li$. Lithium theobromine forms silky crystals, soluble in about half their weight of water. The solution becomes turbid on exposure to the air, owing to the separation of theobromine. Therapeutic trials show that lithium theobromine is as active as four or five times its weight of theobromine.—F. Shdn.

Anagyris fetida; Alkaloids of ——. G. Goessmann. Arch. Pharm., 1906, **244**, 20—24.

Commercial anagyrine hydrobromide has been separated by Partheil and Spasski (Apoth.-Zeit., 1895) into two bases, cytisine, $C_{11}H_{14}N_2O$, and anagyrine, $C_{15}H_{22}N_2O$, the composition of the latter being arrived at indirectly, since it could not be separated in a sufficiently pure state for analysis. The author has attempted to separate the two alkaloids by means of phenylisothiocyanate; the mixed alkaloids were dissolved in alcohol, treated with excess of phenylisothiocyanate, and left in contact for three days. The phenylcytisine-thiourea which separated was filtered off, and the filtrate evaporated on the water-bath, *in vacuo*. The residue was warmed for a short time with dilute hydrochloric acid, when an insoluble oily portion separated. On standing, this deposited white prismatic needles, which were identified as xanthogen-anilide, m. pt. 72°—74° C.; the oil was phenylisothiocyanate. The hydrochloric acid filtrate was made alkaline and the crude anagyrine shaken out with chloroform. The chloroformic extract was freed from the solvent *in vacuo*, and the residue distilled. A trace of a body forming scale-like crystals passed over at 200°, the bulk of the alkaloid distilling at 245° C. under 30 mm. pressure. The base so obtained was a honey-coloured, resinoid, amorphous mass, amounting to about 64 per cent. of the crude base. On analysis, figures were obtained which although not in accordance with the formula of Partheil and Spasski for anagyrine, were not sufficiently diverse to suggest another formula. The base was found to be free from cytisine. Although the method has failed so far to absolutely confirm the formula for anagyrine, it has proved to be of practical value for the separation of the bases, since cytisine can be readily regenerated from the phenylcytisine-thiourea.
—J. O. B.

Mydriatic alkaloids of the genus Datura. E. Schmidt. Arch. Pharm., 1906, **244**, 66—72.

Datura alba. Nees.—This species of *Datura* has been considered to be identical with *D. fastuosa*, concerning the nature of the alkaloids of which various statements have been made. The seeds of two varieties of *D. fastuosa* have been examined—one with white, the other with blue flowers. Those of *Datura fastuosa*, white double-flowered variety, gave 0·20 per cent. of scopolamine and 0·023 per cent. of hyoscyamine. Seeds of *D. fastuosa*, blue double-flowered form, yielded 0·216 per cent. of scopolamine and 0·034 per cent. of hyoscyamine.—J.O.B.

Almonds, bitter; Influence of heat on the toxicity of ——. G. Velardi. Boll. Chim. Farm., 1906, **45**, 65—67. Chem. Centr., 1906, **1**, 1030.

Bitter almonds, some whole and some cut into pieces, were heated in an air-bath, starting from a temperature of 70° C., and rising by increments of 5°, the temperature being maintained constant at each point for two hours and samples of the almonds withdrawn, powdered, allowed to stand in contact with water, distilled, and the distillate tested for hydrocyanic acid. Up to 103° C., hydrocyanic acid was formed from all the test samples, but at 105° C., in traces only, from the whole almonds, whilst above 105° C. it was necessary to macerate the heated almonds with powdered sweet almonds to obtain evidence of hydrocyanic acid at all. In all cases the whole almonds proved more resistant to heat than those cut into pieces, and, indeed, were still capable of yielding traces of hydrocyanic acid after heating to 190° C.

Pure amygdalin when heated rapidly, was found to melt at 208°—210° C.; when heated slowly it began to darken at 170° C., and melted at 180° C., forming a resinous mass. The latter was soluble in water, slightly soluble in 65 per cent. alcohol, and when macerated with water and powdered sweet almonds, immediately yielded hydrocyanic acid. It contained 4·09 of nitrogen, as compared with 2·96 per cent. before heating (calculated for $C_{20}H_{27}O_{11}N$, 3·06 per cent., and for $C_{20}H_{27}O_{11}N+3H_2O$ 2·70 per cent. of nitrogen). The author considers that to render bitter almonds quite harmless, they should be heated to 170° C., at which temperature the amygdalin is stated to become incapable of developing hydrocyanic acid by the action of ferments.—A. S.

Philippine wood oils. A. M. Clover. Philippine J. of Science, 1906, **1**, 191—202.

Wood Oils.—The author defines these as fluid resins having only slight drying power and containing a high proportion of volatile matter, the oily portion of which may amount to as much as 75 per cent. of the resin and consists entirely of sesquiterpene substances. These products closely resemble copaiba and gurjun balsams.

Oil of Supa is obtained from *Sindora Wallichii*, a tree

said to be widely distributed throughout the Philippine islands. A freshly-cut tree is stated to yield about 10 litres of the oil, which in certain districts is used for illuminating purposes. It is mobile, homogeneous, and light yellow in colour, with a slight fluorescence. Its odour is faint but characteristic. The specimen examined by the author had a specific gravity of 0·9202 at 30°/30° C., and an optical rotation of − 31·3° in a 100 mm. tube at 30° C. When cooled below 20° C., it yielded a deposit of white crystals consisting of a hydrocarbon, melting at 63° to 64° C. The oil absorbed oxygen slowly from the air, forming, after several weeks, a thin hard film. When distilled under a pressure of 40 mm., nearly the whole of the oil passed over between 143° and 149° C., the residue being fluid and showing no sign of polymerisation. The distillate had a sp. gr. of 0·9053 at 30°/30° C., and when redistilled, boiled at 255° to 267° C. (760 mm.) leaving practically no residue. It was found that cadinene constituted a large portion of the distillate from the original oil, but no other crystalline derivatives could be obtained. The distillate absorbed oxygen on exposure to the air, gradually becoming viscous, and when spread in a thin layer slowly hardened, and became darker in colour. The optical activity of the oil was destroyed by heat, so that the rotation of a distillate obtained at the ordinary pressure was only −5·4°. The non-volatile portion of the oil (about 27 per cent.) contained solid hydrocarbon (m. pt. 63° to 65° C.), which separated out on the addition of alcohol. When dried *in vacuo* it gave the following results on elementary analysis: Carbon, 85·43; and hydrogen, 14·94 per cent. (total, 100·37). It constituted about 6 per cent. of the original oil of supa.

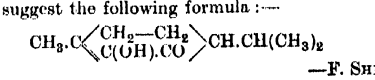
Balao: Oil of Apitong.—This resin is obtained from the *Apitong* tree belonging to the genus *Dipterocarpus*, and is in common use throughout the Islands. It is collected in a cup-shaped cavity cut in the body of the tree. The freshly exuded product is white, but darkens rapidly on standing, and when exposed, in a thin layer, slowly hardens to form a tough durable varnish, for which purpose it is used by the natives of the Philippines. The resin, as thus obtained is a viscous fluid, containing a large amount of granular solid matter in suspension. It has a feeble but distinctive odour, and appears to be soluble in all the ordinary solvents except alcohol. It hardens when treated with steam, and cannot be distilled under reduced pressure owing to frothing and solidification of the partially dehydrated residue, and the only way to remove the whole of the water, which appears to be in a state of chemical combination, is to apply a free flame. Oil continues to distil after removal of the water, and the distillate gradually becomes reddish-green, until at 270° C. signs of decomposition appear in the flask. Specimens distilled in this way yielded about 50 per cent. of distillate, consisting of water with 22 to 28 per cent. of oil. The residue was a dark brittle product. The oil obtained by direct distillation had a b. pt. of 151° to 154° C. at 40 mm., after being fractionated twice under reduced pressure. Its optical rotation at 30° C. was +78·5°, and its sp. gr. at 30°/30° C. 0·9127. No solid crystalline product could be isolated from balao oil, but the author concludes that it is unquestionably a sesquiterpene or mixture of sesquiterpenes.

Malapaho: Oil of Panao.—This resin is obtained from *Dipterocarpus vernicifluus*, the method of extraction being the same as in the case of balao. It dries more slowly than the latter, and is therefore not so widely used. The fresh resin is white, and viscous, and has a characteristic odour. It absorbs oxygen from the air, becoming dark-brown in colour, and when exposed in a thin film, hardens very slowly. When heated to 100° C. its mobility increases, in which respect it differs from balao. It is soluble in ether and chloroform, and partially soluble in alcohol and benzene. When distilled over a free flame it behaves like balao. A specimen examined by the author yielded 25 per cent. of water, 35 per cent. of oil, and 40 per cent. of solid residue. The sesquiterpene from malapaho distilled over almost completely between 256° and 261° C. at 760 mm., and when purified by redistillation under reduced pressure was a colourless product, with a sp. gr. of 0·9165 at 30°/30° C., and a rotation of "−54°" in a 100 mm. tube at 30° C. The solid product was similar to that from balao, but was lighter in colour. On destructive distillation it yielded 50 per cent. of a liquid which partially distilled between 200° and 300° C., leaving a residue resembling rosin oil. None of the constituents of the volatile oil of malapaho could be identified.

Mayapis Resin is obtained from the *Dipterocarpus* tree, mayapis (*D. anisoptera Vidaliana*) and is regarded by Tavera as identical with gurjun balsam. The specimen examined by the author contained 15 per cent. of water, and 25 per cent. of sesquiterpene oil, which could be distilled off without decomposition, leaving a hard residue. The oil purified by redistillation at 17 mm. was light yellow, and had the characteristic odour of the resin. It boiled at 132° to 140° C. (17 mm.) and had a sp. gr. of 0·9056 at 30°/30° C. The original resin was very viscous at the ordinary temperature and hardened when heated to 100° C., forming a white solid. The same effect was produced by exposure to the air, the resin drying much more rapidly than either balao or malapaho. The properties of this sample were quite different from those generally given for gurjun balsam.—C. A. M.

Terpenic compounds; Formation and distribution of —— in the orange. E. Charabot and G. Laloue. Comptes rend., 1906, **142**, 798—801.

Young leaves and stems from new branches were examined in May and in June; in June examination was also made of leaves and stems from branches two to four years old.



In the first case the leaves contained much more essential oil than the stems, both relatively and absolutely; in the second, the proportion had increased in the leaves and diminished in the stems, whilst the absolute amount had increased in both. The third set (from older branches) showed a decrease in the proportion of essential oil in both leaves and stems; but the absolute amount in the leaves had increased, whilst that in the stems had diminished.

The essential oil contained but little citral; that from the leaves more than that from the stems. From the first to the second stage the proportions of citral and of esters had both increased, the combined alcohol more than the free. Later, esterification became less active.

—J. T. D.

Buchu-camphor; Decomposition and synthesis of ——. F. W. Semmler and McKenzie. Ber., 1906, **39**, 1158—1170.

After reviewing previous work upon this subject, the authors examined Buchu-camphor or diosphenol, $C_{10}H_{16}O_2$, which they found to have the following constants:—m. pt. after several recrystallisations, 83°—84° C.; b. pt. at 10 mm., 109°—110° C.; optically inactive, soluble in caustic alkalis, though gradually at first. It only takes up one acetyl or benzoyl group. It gives a mono-oxime, m. pt. 125° C., which cannot be changed into a nitrile. On heating with hydrochloric acid in a sealed tube, it is converted almost entirely into thymol with a little carvacrol. On oxidation with ozone *α*-isopropyl-*γ*-acetyl-*n*-butyric acid is produced. Reduction with sodium and alcohol gives a glycol, $C_{10}H_{20}O_2$, which is oxidised by permanganate to *α*-isopropyl-*α'*-methyl-adipic acid. If Buchu-camphor be oxidised with permanganate, an acid, $C_{10}H_{16}O_4$, is obtained. This on distilling *in vacuo* loses water and passes into a keto-acid, $C_{10}H_{14}O_3$, which melts at 104°—105° C. when crystallised from water, and forms a mono-oxime melting at 182° C. The synthesis was accomplished by the careful oxidation of oxymethylene-menthone, $C_{11}H_{18}O_2$, with ozone. The diketone produced is inverted by acids or alkalis into its enol form, diosphenol, identical with Buchu-camphor, for which the authors suggest the following formula:—

—F. Shdn.

Pinene hydrochloride and camphene hydrochloride. A. Hesse. Ber., 1906, **39**, 1127—1155.

Pinene hydrochloride and camphene hydrochloride can both be made to react with magnesium to form the Grignard magnesium compounds. These, on treatment with

water decompose :—$R.MgX + H_2O = R.H + Mg(OH)X$. Both pinene-magnesium hydrochloride and camphene-magnesium hydrochloride, when decomposed in this way, yield the same camphane, melting at 153° C. The magnesium compounds are readily produced by adding the respective hydrochlorides to a reaction previously started between magnesium and an organic halogen compound. Or, the hydrochloride can be added to an alkyl-magnesium halide already formed. With pinene hydrochloride 80—85 per cent. is converted into the magnesium compound, the rest chiefly into hydrodicamphene, $C_{20}H_{34}$. About 60 per cent. of camphene hydrochloride is converted into the magnesium compound, the rest into hydrodicamphene, which, as far as could be ascertained, was identical with that obtained from pinene. If pinene-magnesium hydrochloride be oxidised by the air and decomposed with water, borneol is the principal product, with some hydrodicamphene and a little isoborneol. Camphene-magnesium hydrochloride on oxidation and treatment with water gives 45 per cent. of alcohols, 2/3 borneol and 1/3 isoborneol, 21 per cent. of hydrodicamphene, and about 34 per cent. of camphene and camphane, but the camphane produced in every case is inactive. But borneol and hydrodicamphene whenever produced are active, if an active substance has been the starting point. The author concludes that pinene hydrochloride and bornyl chloride are identical. Also, that the chlorine atom in camphene hydrochloride is attached to the same atom to which chlorine is attached in pinene hydrochloride; and that borneol and isoborneol are stereoisomeric secondary alcohols. The products of the reaction were as a rule complex mixtures of the following compounds:—unchanged substance, pinene or camphene hydrochloride; camphane and camphene; borneol and isoborneol; hydrodicamphene. Details are given for the determination of their respective amounts.—F. Shdn.

Ethyl alcohol free from aldehyde: Preparation of — for use in oil and fat analysis. F. L. Dunlap. J. Amer. Chem. Soc., 1906, **28**, 395—398.

The method proposed is a modification of that devised by Winkler (this J., 1905, 1253), for the preparation of pure absolute ethyl alcohol. One litre of 95 per cent. alcohol is well mixed with a solution of 1·5 grms. of silver nitrate in about 3 c.c. of water, and a cold solution of 3 grms. of potassium hydroxide (purified by alcohol) in 10—15 c.c. of alcohol is slowly poured in, without shaking. The alcohol is allowed to stand over night or until the precipitated silver oxide has settled, and the clear solution is withdrawn and distilled. The product dissolves potassium hydroxide to a colourless solution. The method is not applicable to methyl alcohol.—A. S.

Chloroform and ether; Evolution of heat on mixing ——. L. Rosenthaler. Arch. Pharm., 1906, **244**, 24—25.

When chloroform and ether are mixed, under varying conditions, a notable rise of temperature invariably ensues, some compound being undoubtedly formed.—J. O. B.

Polyhydric phenols; Catalytic action of alkali and alkaline-earth salts in fixation of atmospheric oxygen by ——. E. Fouard. Comptes rend., 1906, **142**, 796—798.

In presence of halides, the absorption of oxygen from the air by solutions of guaiacol and quinol (hydroquinone) is very much more rapid than without them. The order of activity of the metals tried, is:—sodium, manganese, calcium, potassium, barium, lithium, strontium. The first four of these are among the elements always found in living organisms. Oxy-salts—sulphates, nitrates, &c.—do not exhibit this accelerating power in the same way as halides.—J. T. D.

Benzyl- and phenylborneols, and the products of their dehydration, benzyl- and phenylcamphenes. A. Haller and E. Bauer. Comptes rend., 1906, **142**, 677—681.

Secondary α-benzylborneol $C_8H_{14}\begin{cases}CH\cdot CH_2C_6H_5\\ \vdots\\ CHOH\end{cases}$ is obtained quantitatively as a viscous oil, by reducing benzyl camphor in absolute alcohol by means of a large excess of sodium. It boils at 179°—181° C. under 13 mm., has sp. gr 1·1325 and rotary power $[\alpha]_D = +26°\ 10'$, and yields an acid phthalate, which on saponification produces a benzylborneol having a slightly higher rotatory power than the original. The corresponding *benzylcamphene* is obtained along with the phthalate, or by heating benzylborneol with formic acid or with pyruvic acid. As the camphenes obtained by these different methods, however, differ in boiling point and in rotatory power, the original benzylborneol is probably mixed with benzylisoborneol.

Tertiary β-benzylborneol $C_8H_{14}\begin{cases}CH_2\\ \vdots\\ C(OH)CH_2C_6H_5\end{cases}$ prepared by treating camphor with phenylmagnesium bromide in ethereal solution, boils at 165°—170° C. under 10 mm., and has a rotatory power $[\alpha]_D = -12°\ 0'$. It is readily dehydrated by heating with pyruvic or formic acid, or phthalic anhydride, yielding benzylcamphene melting at 24° C., and lævorotatory $[\alpha]_D = -60°\ 44'$. A small amount of a liquid isomeride is at the same time produced. The corresponding tertiary phenyl compounds are similar and similarly obtained.

Tertiary Phenylborneol $C_8H_{14}\begin{cases}CH_2\\ \vdots\\ C(OH)C_6H_5\end{cases}$, is prepared like tertiary benzyl-borneol. It is an oil distilling between 157° and 158° C. under 12 mm. At 40° C. it becomes a crystalline mass. On heating it with pyruvic acid, *β*-phenylcamphene, $C_8H_{14}\begin{cases}CH_2\\ \vdots\\ C.C_6H_5\end{cases}$ is produced.—J. T. D.

Oxidation of ortho-, meta-, and para-compounds; Relative rates of ——. H. Bradshaw. Amer. Chem. J., 1906, **35**, 326—335.

A study was made of the relative rates of oxidation by potassium permanganate, of the three isomerides of each of the following:—hydroxybenzoic acids, aminobenzoic acids, nitrophenols, nitranilines and toluidines. Uniformity was shown only when oxidation was carried out in alkaline solution; in this case the differences in the rates of oxidation were quite marked, the rate decreasing from the *m*- to the *p*-compound. The effect of alkali depends rather on its concentration than on the quantity present.—T. F. B.

Tropeines; Preparation and properties of some new ——. H. A. D. Jowett and A. C. O. Hann. Chem. Soc. Trans., 1906, **89**, 357—365.

Jowett and Marshall have previously shown that the specific rotatory power of pilocarpine or iso-pilocarpine in aqueous solution is diminished by addition of caustic alkali, a minimum value being obtained when one molecular proportion of alkali is present. Furthermore, the solution thus treated no longer exhibits the characteristic physiological action of pilocarpine (Marshall, J. Physiol., 1904, **31**, 153). This change is attributed to the opening of the lactone ring in the pilocarpine molecule, with formation of the corresponding hydroxy-acid. The authors find that this difference in action between a lactone and the corresponding hydroxy-acid is also shown by terebyl- and phthalidecarboxyl-tropeïnes, which produce an atropine-like effect on the heart, but lose this action after a molecular proportion of alkali has been added to the base.

Ladenburg has stated that the mydriatic action of a tropeïne depends not only on the presence of a tropine complex, but also on the nature of the acyl group attached to it, which must contain (1) a benzene residue, (2) an aliphatic hydroxyl in the side-chain containing the carboxyl group. The authors' experiments with five new tropeïnes, *viz.*, phthalidecarboxyl-, terebyl-, protocatechyl-, methylparaconyl-, and glycollyl-tropeïnes, arranged in order of activity, show that whilst the conditions given by Ladenburg appear to be those most favourable for the development of mydriatic action, yet terebyltropeïne which does not contain a benzene nucleus exhibits a distinct mydriatic action. All the new tropeïnes mentioned were much less active than atropine or homatropine.

Glycollyltropeine, $CH_2(OH).CO.C_8H_{14}ON$, was prepared by neutralising tropine with glycollic acid and digesting the resulting solution with dilute hydrochloric acid (1:40) for 24 hours on the water-bath. After purification, the base formed laminar crystals melting at 113°—114° C.; m. pt. of the hydrochloride is 171°—172° C. The remaining four tropeines were prepared by passing hydrochloric acid gas through a solution of tropine neutralised with the acid in question, and maintained at a suitable temperature for two to three hours. *Methylparaconyltropeine*,

$$CO<\begin{matrix}O.CH(CH_3)\\ -CH_2-\end{matrix}>CH.CO.C_8H_{14}ON,$$

was obtained as a colourless oil; m. pt. of hydrobromide, 196°—197° C. *Terebyltropeine*

$$CO<\begin{matrix}O.C(CH_3)_2\\ -CH_2-\end{matrix}>CH.CO.C_8H_{14}ON,$$

formed small diamond-shaped crystals, melting at 66°—67° C.; m.pt. of hydrochloride, 82° C. *Phthalidecarboxyltropeine*,

$$C_6H_4<\begin{matrix}CH-CO.C_8H_{14}ON\\ CO-O\end{matrix},$$

formed square laminar crystals, melting at 79°—80° C.; m. pt. of hydrochloride, 242°—244° C., with decomposition. *Protocatechyltropeine*, $C_6H_3(OH)_2.CO.C_8H_{14}ON$, separated from alcohol in stout acicular crystals, melting at 253°—254° C., with decomposition.—A. S.

United States Patents.

Alkyloxyacetyl cyanamide and process of making same. A. H. C. Heitmann and E. C. Clemmensen, Assignors to Parke, Davis and Co., Detroit, Mich. U.S. Pat. 814,693, March 13, 1906.

Alkylhydroxyacetylcyanamides are obtained by the condensation of alkylated hydroxyacetic acids and cyanamide or urea, the oxygen of which is substituted. By hydrolysis of the product, the corresponding alkylhydroxyacetylurea is obtained. Diethylhydroxyacetyl cyanamide, obtained by condensing diethylhydroxyacetic acid with cyanamide, is a colourless crystalline substance of m. pt. 235° C., soluble in water and alcohol, but insoluble or only slightly soluble in organic solvents.—T. F. B.

Alkylaminoacetopyrocatechol and process of making same. F. Stolz, Assignor to Farbwerke vorm. Meister, Lucius und Brüning, Höchst on Maine, Germany. U.S. Pat. 815,653, March 20, 1906.

See Eng. Pat. 22,064 of 1904; this J., 1905, 43.—T. F. B.

Medicines; Process of making ——. R. Gross, Rastenberg, Assignor to Ferro-Phosphat Ges. E. Schramm und Co., Hamburg, Germany. U.S. Pat. 816,547, March 27, 1906.

See Fr. Pat. 343,174 of 1904; this J., 1904, 1040.—T. F. B.

French Patent.

Organo-magnesium compounds; Process for preparing and oxidising —— [Preparation of borneol]. Chem. Fabr. auf Actien, vorm. E. Schering. Fr. Pat. 359,547, Nov. 2, 1905.

By the action of magnesium on a solution of pinene hydrochloride, hydrobromide or hydriodide in a suitable solvent (*e.g.*, ether, or a hydrocarbon), in presence of some substance which acts catalytically, (iodine, an alkyl or aryl halide, &c.), organo-magnesium halides of the general formula $C_{10}H_{17}MgX$ are obtained in good yield (80 to 85 per cent.); these possess the property of absorbing oxygen, forming complex products, which are converted into borneol by decomposition with dilute acids.—T. F. B.

German Patents.

Anhydrides of monobasic organic acids; Process for preparing ——. Verein f. Chem. Ind. Ger. Pat. 163,103, June 26, 1902. Addition to Ger. Pat. 161,882, March 30, 1902.

The mixture of alkali and alkaline-earth salts of the acid is treated with phosphoryl chloride or carbonyl chloride, instead of with sulphuryl chloride as in the principal patent (this J., 1905, 1323). The yields are stated to be much higher when the above modification is introduced, and the risk of the formation of mixed chlorides is avoided.—T. F. B.

Phenylglycin; Process of preparing ——. E. Lippmann. Ger. Pat. 163,515, June 9, 1903.

Phenylglycinamylester is saponified by heating with concentrated caustic soda solution, and the sodium salt of phenylglycin is then liberated by means of acid; the saponification had only been possible previously by the use of alcoholic alkali solutions. The yield by the above process is stated to be about 97 per cent. of the theoretical yield, whereas that from aniline and monochloroacetic acid is only about 33 per cent.—T. F. B.

1.3-Dialkylpyrogallol ethers, Process of preparing ——. Basler Chem. Fabrik. Ger. Pat. 162,658, June 16, 1903.

1.3-Dialkylpyrogallol ethers are obtained from the trialkyl ethers of gallic acid or of pyrogallol by heating under pressure with alkali or alkaline-earth hydroxides in aqueous or alcoholic solution. The products, which had formerly only been obtained in small quantity from beech wood tar, are applicable to the preparation of perfumes, photographic developers, dyestuffs and pharmaceutical preparations.—T. F. B.

Beech wood tar; Process for preparing an alkali-soluble product from —— which is solid at the ordinary temperature. Chem. Fabr. Flörsheim Dr. H. Noerdlinger. Ger Pat. 163,446, June 18, 1903. III., page 367.

Glyoxylic acid, its esters and amide, and phenylglycin and its derivatives; Process for preparing —— from oxalic acid and its derivatives by electrolytic reduction. Kinzlberger und Co. Ger. Pat. 163,842, Sept. 10, 1903.

Oxalic acid and its esters and amide, as well as its other derivatives which are capable of reduction, are reduced electrolytically, with a lead cathode, in presence of sulphuric acid (containing 2 to 90 per cent. of monohydrate), in a cell provided with a diaphragm. The current may be from 2 to 10 ampères per sq. m., and the temperature of the electrolyte must be kept low. Glyoxylic acid and its derivatives are produced in good yield. By replacing the oxalic acid by oxanilic acid or its derivatives, phenylglycin or one of its derivatives is produced.—T. F. B.

Esters from alcohols and phenols; Process of preparing ——. J. Houben. Ger. Pat. 162,863, Dec. 8, 1903.

This process is for the esterification of alcohols and phenols which are unstable under the ordinary conditions of preparation (*e.g.*, benzyl alcohol). The alcohol is added to an ethereal solution of an alkylmagnesium chloride, and after some time, the anhydride or chloride of the fatty acid, also in ethereal solution, is added, the mixture being cooled during the whole reaction. The following equations represent an instance of such an esterification:—

$$C_6H_5.CH_2OH + C_2H_5MgCl = C_6H_5.CH_2OMgCl + C_2H_6;$$
$$C_6H_5CH_2OMgCl + (CH_3CO)_2O = C_6H_5.CH_2O.COCH_3 + CH_3CO.OMgCl.$$

—T. F. B.

Condensation products from aldehydes and negatively substituted acetic acids; Process of preparing ——. E. Knoevenagel. Ger. Pat. 164,296, Jan. 23, 1904. Addition to Ger. Pat. 156,560, Dec. 16, 1902. (See this J., 1905, 689.)

Cyclic aldehydes are condensed with equimolecular pro-

water decompose :—$R.MgX + H_2O = R.H + Mg(OH)X$. Both pinene-magnesium hydrochloride and camphene-magnesium hydrochloride, when decomposed in this way, yield the same camphane, melting at 153° C. The magnesium compounds are readily produced by adding the respective hydrochlorides to a reaction previously started between magnesium and an organic halogen compound. Or, the hydrochloride can be added to an alkyl-magnesium halide already formed. With pinene hydrochloride 80—85 per cent. is converted into the magnesium compound, the rest chiefly into hydrodicamphene, $C_{20}H_{34}$. About 60 per cent. of camphene hydrochloride is converted into the magnesium compound, the rest into hydrodicamphene, which, as far as could be ascertained, was identical with that obtained from pinene. If pinene-magnesium hydrochloride be oxidised by the air and decomposed with water, borneol is the principal product, with some hydrodicamphene and a little isoborneol. Camphene-magnesium hydrochloride on oxidation and treatment with water gives 45 per cent. of alcohols, 2/3 borneol and 1/3 isoborneol, 21 per cent. of hydrodicamphene, and about 34 per cent. of camphene and camphane, but the camphane produced in every case is inactive. But borneol and hydrodicamphene whenever produced are active, if an active substance has been the starting point. The author concludes that pinene hydrochloride and bornyl chloride are identical. Also, that the chlorine atom in camphene hydrochloride is attached to the same atom to which chlorine is attached in pinene hydrochloride; and that borneol and isoborneol are stereoisomeric secondary alcohols. The products of the reaction were as a rule complex mixtures of the following compounds:—unchanged substance, pinene or camphene hydrochloride; camphane and camphene; borneol and isoborneol; hydrodicamphene. Details are given for the determination of their respective amounts.—F. Shdn.

Ethyl alcohol free from aldehyde: Preparation of — for use in oil and fat analysis. F. L. Dunlap. J. Amer. Chem. Soc., 1906, **28**, 395—398.

The method proposed is a modification of that devised by Winkler (this J., 1905, 1253), for the preparation of pure absolute ethyl alcohol. One litre of 95 per cent. alcohol is well mixed with a solution of 1·5 grms. of silver nitrate in about 3 c.c. of water, and a cold solution of 3 grms. of potassium hydroxide (purified by alcohol) in 10—15 c.c. of alcohol is slowly poured in, without shaking. The alcohol is allowed to stand over night or until the precipitated silver oxide has settled, and the clear solution is withdrawn and distilled. The product dissolves potassium hydroxide to a colourless solution. The method is not applicable to methyl alcohol.—A. S.

Chloroform and ether; Evolution of heat on mixing ——. L. Rosenthaler. Arch. Pharm., 1906, **244**, 24—25.

When chloroform and ether are mixed, under varying conditions, a notable rise of temperature invariably ensues, some compound being undoubtedly formed.—J. O. B.

Polyhydric phenols; Catalytic action of alkali and alkaline-earth salts in fixation of atmospheric oxygen by ——. E. Fouard. Comptes rend., 1906, **142**, 796—798.

In presence of halides, the absorption of oxygen from the air by solutions of guaiacol and quinol (hydroquinone) is very much more rapid than without them. The order of activity of the metals tried, is:—sodium, manganese, calcium, potassium, barium, lithium, strontium. The first four of these are among the elements always found in living organisms. Oxy-salts—sulphates, nitrates, &c.—do not exhibit this accelerating power in the same way as halides.—J. T. D.

Benzyl- and phenylborneols, and the products of their dehydration, benzyl- and phenylcamphenes. A. Haller and E. Bauer. Comptes rend., 1906, **142**, 677—681.

Secondary α-benzylborneol $C_8H_{14}\begin{cases}CH\cdot CH_2C_6H_5\\ \vdots\\ CHOH\end{cases}$ is obtained quantitatively as a viscous oil, by reducing benzyl camphor in absolute alcohol by means of a large excess of sodium. It boils at 179°—181° C. under 13 mm., has sp. gr 1·1325 and rotary power $[\alpha]_D = +26°\ 10'$, and yields an acid phthalate, which on saponification produces a benzylborneol having a slightly higher rotatory power than the original. The corresponding *benzylcamphene* is obtained along with the phthalate, or by heating benzylborneol with formic acid or with pyruvic acid. As the camphenes obtained by these different methods, however, differ in boiling point and in rotatory power, the original benzylborneol is probably mixed with benzylisoborneol.

Tertiary β-benzylborneol $C_8H_{14}\begin{cases}CH_2\\ \vdots\\ C(OH)CH_2C_6H_5\end{cases}$ prepared by treating camphor with phenylmagnesium bromide in ethereal solution, boils at 165°—170° C. under 10 mm., and has a rotatory power $[\alpha]_D = -12°\ 0'$. It is readily dehydrated by heating with pyruvic or formic acid, or phthalic anhydride, yielding benzylcamphene melting at 24° C., and lævorotatory $[\alpha]_D = -60°\ 44'$. A small amount of a liquid isomeride is at the same time produced. The corresponding tertiary phenyl compounds are similar and similarly obtained.

Tertiary Phenylborneol $C_8H_{14}\begin{cases}CH_2\\ \vdots\\ C(OH)C_6H_5\end{cases}$, is prepared like tertiary benzyl-borneol. It is an oil distilling between 157° and 158° C. under 12 mm. At 40° C. it becomes a crystalline mass. On heating it with pyruvic acid, *β*-phenylcamphene, $C_8H_{14}\begin{cases}CH_2\\ \vdots\\ C.C_6H_5\end{cases}$ is produced.—J. T. D.

Oxidation of ortho-, meta-, and para-compounds; Relative rates of ——. H. Bradshaw. Amer. Chem. J., 1906, **35**, 326—335.

A study was made of the relative rates of oxidation by potassium permanganate, of the three isomerides of each of the following:—hydroxybenzoic acids, aminobenzoic acids, nitrophenols, nitranilines and toluidines. Uniformity was shown only when oxidation was carried out in alkaline solution; in this case the differences in the rates of oxidation were quite marked, the rate decreasing from the *m*- to the *p*-compound. The effect of alkali depends rather on its concentration than on the quantity present.—T. F. B.

Tropeines; Preparation and properties of some new ——. H. A. D. Jowett and A. C. O. Hann. Chem. Soc. Trans., 1906, **89**, 357—365.

Jowett and Marshall have previously shown that the specific rotatory power of pilocarpine or iso-pilocarpine in aqueous solution is diminished by addition of caustic alkali, a minimum value being obtained when one molecular proportion of alkali is present. Furthermore, the solution thus treated no longer exhibits the characteristic physiological action of pilocarpine (Marshall, J. Physiol., 1904, **31**, 153). This change is attributed to the opening of the lactone ring in the pilocarpine molecule, with formation of the corresponding hydroxy-acid. The authors find that this difference in action between a lactone and the corresponding hydroxy-acid is also shown by terebyl- and phthalidecarboxyl-tropeïnes, which produce an atropine-like effect on the heart, but lose this action after a molecular proportion of alkali has been added to the base.

Ladenburg has stated that the mydriatic action of a tropeïne depends not only on the presence of a tropine complex, but also on the nature of the acyl group attached to it, which must contain (1) a benzene residue, (2) an aliphatic hydroxyl in the side-chain containing the carboxyl group. The authors' experiments with five new tropeïnes, *viz.*, phthalidecarboxyl-, terebyl-, protocatechyl-, methylparaconyl-, and glycollyl-tropeïnes, arranged in order of activity, show that whilst the conditions given by Ladenburg appear to be those most favourable for the development of mydriatic action, yet terebyltropeïne which does not contain a benzene nucleus exhibits a distinct mydriatic action. All the new tropeïnes mentioned were much less active than atropine or homatropine.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 339.)

APPARATUS, Etc.

French Patent.

Gases; Apparatus for [Automatic] analysis of ——. Monopol Betriebskontroll-Apparate K. Stembock. Fr. Pat. 359,352, Nov. 2, 1905. Under Int. Conv., Dec. 7, 1904.

The gas to be analysed, is aspirated through an inverted U-shaped tube, which serves to measure off the sample, and is contained in a vessel into which water is continuously flowing. When the water reaches a certain level in the vessel, the gas inlet- and outlet tubes become sealed off, and the measuring tube then contains a definite volume of the sample. As the water continues to rise in the vessel, the sample is driven over into a second vessel containing an appropriate absorbent liquid; the unabsorbed gas is led up into an inverted, graduated bell, floating in a non-volatile liquid, and the height to which the bell rises indicates the volume of the unabsorbed, and hence the percentage of absorbed gas. The apparatus is provided with an automatic device for registering on a diagram the proportion of absorbed gas; and various devices for automatically filling and discharging the apparatus, adjusting the pressures, &c., are described.—H. B.

INORGANIC—QUANTITATIVE.

Cadmium; Determination of ——. H. Baubigny. Comptes rend., 1906, **142**, 577—580.

Cadmium sulphide in contradistinction to all other cadmium salts, which are easily decomposed on heating, especially in contact with organic matter, can be heated for the incineration of the filter paper, without any loss of metal, to a temperature of 500° C., provided always that it contains neither traces of a volatile salt such as the chloride, nor an organic salt, which would decompose at this temperature. A very accurate method of estimating cadmium is based on this observation. (For details of method, see following abstract.)—E. F. A.

Cadmium; Determination of ——. H. Baubigny. Comptes rend., 1906, **142**, 792—793.

The solution of sulphate, containing not more (unless the amount of cadmium be considerable) than 2 c.c. of concentrated sulphuric acid per 100 c.c., is heated to from 85°—90° C., hydrogen sulphide is passed through it till it has cooled to 50°—55° C., and it is then allowed to stand for three to four hours. The precipitate thus formed, is very dense and readily removed from the precipitating vessel. It is filtered and washed with water (any sulphide adhering to the delivery tube is dissolved by hydrochloric acid, which is kept for use at a later stage), the filter dried by blotting paper, put damp into a porcelain crucible, which is placed in a porcelain capsule and carefully heated till the drying and charring of the paper are complete. Then the flame is increased, an inverted funnel being placed as a jacket round the crucible, till the filter ignites and burns away. The sulphide is then, after cooling, dissolved in the hydrochloric acid used to clean the delivery tube, and evaporated with a few drops of sulphuric acid, all these operations being conducted in the crucible. When the temperature reaches 400°—450° C., pure and stable cadmium sulphate remains, and is weighed after cooling.—J. T. D.

Hydrosulphites and hydrosulphite compounds; Determination of ——. A. Seyewetz and Bloch. Rev. Gén Mat. Col., 1906, **10**, 101—103.

When sodium hydrosulphite is added to a solution of silver chloride in excess of ammonia, there is an immediate precipitation of silver: $2AgCl + 4NH_3 + Na_2S_2O_4 + 2H_2O = 2NaCl + 2(NH_4)_2SO_3 + Ag_2$. The amount of silver produced, depends solely upon the amount of hydrosulphite present, and is not affected by the oxidation products, sulphites, bisulphites, or thiosulphates. The sodium hydrosulphite solution is added to four or five times the equivalent amount of silver chloride dissolved in excess of ammonia. The silver is collected, ignited, and weighed. The amount of formaldehyde-hydrosulphite, CH_2O, $NaHSO_2$, H_2O, present in "hyraldite" for instance, can be determined as follows: The solution is added to four times the equivalent quantity of silver chloride in excess of ammonia, and the mixture heated nearly to boiling for four to five minutes. The silver is collected and weighed. One molecule of the formaldehyde compound reduces 2 mols. of silver chloride.—F. Shdn.

Sodium sulphide; Analysis of commercial ——. R. Blondel. Bull. Soc. Ind. Rouen, 1906; Chem. Zeit., 1906, **30**, Rep. 94.

The novelty of the Battegay method consists in the ease with which the sulphide can be determined in presence of thiosulphate and other technical admixtures. The free alkali is first saturated with acetic acid, and a titrated solution of zinc sulphate is added, the end point being detected by means of cadmium sulphate paper. When the test paper no longer assumes a yellow tinge, the precipitation of the zinc sulphide is complete.—C. S.

Arsenic in wall-papers, fabrics, &c.; Note on the application of the electrolytic method to the determination of ——. T. E. Thorpe. Chem. Soc. Proc., 1906, **22**, 73.

Known quantities of the material, as a rule about 2 grms., are moistened with lime water, mixed with calcined magnesia, dried, and charred. The ash is treated with dilute sulphuric acid, half a grm. of potassium meta-bisulphite added, the solution boiled and diluted to a definite volume, and the whole or an aliquot portion, depending on the amount of arsenic suspected to be present, is added to the electrolytic arrangement already described (this J., 1903, 965). The deposit of arsenic so obtained is then compared with deposits obtained in precisely the same way by the addition of known quantities of arsenic, ranging from 0·005 to 0·0125 mgrm. of arsenious oxide, to materials free from arsenic, as in the method of testing brewing materials for arsenic already described (*loc. cit.*). A single incineration of the suspected material suffices for several tests. The amounts of lime-water and magnesia recommended to be used have been proved by direct experiment to retain amounts of arsenic ranging from 0·0025 to 5 mgrms. when contained in 2 grms. of wool or paper.

Many samples of woollen materials met with in commerce contain very notable quantities of arsenic, arising probably from the wide-spread use of arsenical dips.

Acid; Volumetric determination of free —— *in the presence of iron salts.* C. C. Ahlum. Chem. Soc. Trans., 1906, **89**, 470—473.

In the volumetric determination of free acid in chalybeate waters it is necessary to remove iron from the solution before titrating with alkali, as otherwise the colour change of the indicator is obscured. The method recommended by the author for separating the iron is based upon the fact that with ferric salts, sodium dihydrogen phosphate gives a precipitate of ferric phosphate, with simultaneous formation of free acid, according to the equation:—

$$Fe_2(SO_4)_3 + 2NaH_2PO_4 = 2FePO_4 + Na_2SO_4 + 2H_2SO_4.$$

100 c.c. of the acid solution containing iron salts are treated with excess of a 10 per cent. solution of sodium dihydrogen phosphate, the precipitate is filtered off, and the filtrate titrated with N/10 sodium hydroxide solution, using Methyl Orange as indicator. This gives the amount of free acid originally contained in the solution *plus* that liberated from the ferric salts present, and the latter quantity can be calculated from the proportion of ferric salts determined in a separate portion of the solution.

—A. S.

ORGANIC—QUANTITATIVE.

Dimethyl sulphate for determining tar oils in mixtures with rosin and mineral oils, and its behaviour towards fatty oils, oil of turpentine and pinoline. E. Valenta. III., page 366.

Malt analysis; Determination of extract values in —— by the refractometer. O. Mohr. Woch. f. Brau., 1906, **23**, 136—140.

The author has examined a large number of worts, obtained in the ordinary course of the analysis of malt by the standard German method, in the Zeiss immersion refractometer, and has compared the results with those of careful determinations of the extract values made by means of the pyknometer. The refractometer values of the extract were taken as the differences between the scale-readings for the worts and the scale-reading for pure water at the same temperature (17·5° C.). In this way the value of 1° increase of scale-reading was calculated in terms of degrees Balling determined by the pyknometer, and the average was found to be as nearly as possible 0·25° Balling. This factor can be used with confidence for the paler classes of malt, *i.e.*, those yielding worts of a colour below that corresponding to "type 40" on the German colour-scale. With malts of a darker colour than type 40, closer results are obtained if 0·04° Balling be subtracted from the calculated extract values. The greater divergence between the refractometer and the pyknometer extract values with dark malts, appears to be connected with the lower diastatic power of this kind of malt, and the divergences seem to be greater the lower the degree of saccharification obtained, *i.e.*, the lower the ratio of maltose to dextrin. It is open to question whether in such cases the error does not really lie in the pyknometric values rather than in the refractometer values. The above factor of 1° of refractometer increase = 0·25° Balling is only valid for worts of the usual concentration as obtained in malt analysis, *viz.*, from 7·5° to 8·6° Balling. It cannot be used for more dilute solutions, as in beer analysis, nor for more concentrated solutions, as in brewery worts. The value of the factor for the same wort increases as the concentration is decreased. For beer extracts the Ackermann slide rule has been designed, but for strong brewery worts no data are as yet available. Any observations in this direction should take into account not only the concentration, but also the maltose : dextrin ratio, representing the degree of saccharification.—J. F. B.

Milk; Determination of proteids in. A. Trillat and Sauton. Comptes rend., 1906, **142**, 794—796.

Five c.c. of milk are diluted with distilled water to 25 c.c., and boiled for five minutes; five drops of commercial formalin are added, and the liquid is again boiled for two to three minutes. After five minutes, 5 c.c. of 1 per cent. acetic acid are added, and the liquid is well shaken. The pulverulent precipitate is allowed to settle, then filtered off and washed, the fat is extracted from the contents of the filter by acetone in a Soxhlet apparatus, and the residual proteïds dried at 75°—80° C. and weighed. The method is applicable to diluted, skimmed, sterilised, or curdled milk, and the authors have proved that the whole of the proteïds are separated by the method, and that they undergo no change in composition or in weight. The fat, of course, can be determined after evaporation of the acetone.—J. T. D.

Coca leaves; Analysis of the alkaloids of Java ——. A. de Jong. Rec. trav. Chim. Pays-Bas, 1906, **25**, 1; Chem.-Zeit., 1906, **30**, Rep., 110—111.

The moisture is determined by heating 1 grm. of the alkaloids on the water bath. To determine the impurities the alkaloids are heated with 30 c.c. of 0·3-N barium hydroxide solution for two to three hours in a flask fitted with a condenser. The liquid is passed through a tared filter and the residue washed. After shaking the residue with dilute hydrochloric acid the insoluble portion is filtered off and weighed. The δ-isotropinic acid is extracted from the hydrochloric acid solution by shaking three times with ether and weighing the residue left on evaporating the ether. The undecomposed alkaloids are determined by adding excess of ammonia to the hydrochloric acid solution and shaking out with ether. The barium hydroxide filtrate, containing benzoic, cinnamic, and ε-isotropinic acids, is treated with 12 c.c. of N/1-sulphuric acid and shaken out three times with ether. The ether is shaken with 20 c.c. of barium hydroxide solution, through which carbon dioxide is passed to remove the excess of barium. After evaporation of the filtrate, the residue is dried at 110°—120° C. The barium salts of the acids are decomposed with 2—3 c.c. of concentrated hydrochloric acid and the almost insoluble ε-isotropinic acid is collected on a tared filter. The cinnamic acid in the filtrate is determined by means of bromine, and the benzoic acid by difference. In order to determine the bases and the γ-isotropinic acid, the sulphuric acid solution, after shaking out with ether, is treated with 20 c.c. of N/1-barium hydroxide solution, carbon dioxide passed through, and the liquid filtered. After partial evaporation, hydrochloric acid is added, causing the precipitation of γ-isotropinic acid, which is filtered off. The filtrate, after treating with excess of sulphuric acid, is again filtered and made alkaline. The pseudotropine is obtained by shaking out with chloroform, and the amount of ecgonine is determined by difference.
—F. Shdn.

Ethyl alcohol free from aldehyde; Preparation of —— for use in oil and fat analysis. F. L. Dunlap. XX., page 391.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 339.)

Xanthic leucomaines; Action of —— on copper. N. Slomnesco. Comptes rend., 1906, **142**, 789—790.

Theobromine, theophylline, urea, and probably other xanthic leucomaïnes, precipitate copper from its solution, in the cuprous condition. Probably this is not merely a case of simple reduction, but also one of combination of the copper with the bases; for when these bases are boiled with copper filings, precipitation of yellow hydroxide also occurs. The smallest trace of copper is precipitated by these reagents, and it is probably because of this precipitation in the organism, that small amounts of copper do not prove poisonous.—J. T. D.

English Patent.

Tobacco; Process for improving inferior qualities of ——. P. Hondius, Utrecht, Holland. Eng. Pat. 16,025, Aug. 4, 1905.

An extract is prepared from waste or residues (stalks, leaves and the like) of tobacco of better quality. This extract is evaporated to a syrup or more or less solid condition and can be used, when diluted, for impregnating inferior kinds of tobacco.—W. P. S.

Trade Report.

Truck Acts; Committee on the ——.

The Home Secretary has appointed a Committee to inquire into the working of the Truck Acts.

The Right Hon. Thomas Shaw, M.P., Lord Advocate for Scotland, is Chairman of the Committee, and the members are:—

Mr. E. A. Brotherton, M.P. for Wakefield (a chemical manufacturer);

Mr. F. Cawley, M.P. for the Prestwich Division of Lancashire (a bleacher and calico printer);

Mr. M. Delevingne, of the Home Office;

Mr. J. Ramsay Macdonald, M.P. for Leicester (Labour);

Mr. F. Maddison, M.P. for Burnley (Labour);

Mrs. H. J. Tennant; and

Mr. A. F. Yarrow, of the firm of Yarrow and Co., shipbuilders.

The terms of reference are "to inquire into the operation of the Truck Acts, and to consider and report what amendments, or extensions, of those Acts, or changes in their administration, are desirable; particularly whether fines and deductions from wages should be prohibited; and further, to consider and report whether the practice of shop assistants and certain classes of workpeople being lodged and boarded by their employers gives rise to abuses needing remedy by an extension of the Truck Acts or by other action of the State."

Correspondence on the subject should be addressed to the Secretary, Mr. T. E. Bettany, at the Home Office, Whitehall, S.W.

NATAL: IMPORT TRADE OF —— IN 1905.

Bd. of Trade J., April 12, 1906.

THE following are particulars of the imports into Natal during the years 1904 and 1905, the figures for each half-year being shown separately:—

Articles.	1904.		1905.	
	Jan.–June.	July–Dec.	Jan.–June.	July–Dec.
	1,000's of £.	1,000's of £.	1,000's of £.	1,000's of £.
Candles	30	27	23	27
Cement	28	20	13	24
Earthenware	31	26	28	32
Food and drink—				
Beverages (ale and beer, spirits and wine)	164	160	157	148
Sugar	51	52	117	37
Glass and glassware	37	43	34	41
Leather and leather manufactures	163	177	210	228
Nitrate of soda	—	40	39	27
Oils (paraffin, &c.)	74	60	62	80
Painters' colours	23	22	20	19
Paper	32	32	33	32
Soap	46	35	47	32

GERMANY: TRADE OF ——.

For. Off. Ann. Series, No. 3544.

THE following tables show the value of certain imports into and exports from Germany, during the last three years:—

Imports.

Articles.	In 1,000*l.*		
	1903.	1904.	1905.
Coal, coke and other fuel	8,113·7	8,381·7	10,136·8
Tar, pitch, resin, asphalt	2,267·2	2,414·6	2,504·4
Earths, ores, precious metals	26,683·8	37,426·3	28,834
Iron and manufactures of iron	2,815·5	3,046·9	3,156·5
Tin and manufactures of tin	1,813·5	1,870·6	1,757
Copper and manufactures of copper	6,612·1	8,439	8,273·4
Zinc and manufactures of zinc	559·6	610·2	682·2
Lead and manufactures of lead	666·6	784·4	996·3
Drugs, dyestuffs, chemical products	13,718·8	14,902·6	15,896·9
Leather and manufactures of leather	3,471·7	3,484·8	3,568
Oils and fats	11,446·3	11,358·5	12,510·6
Petroleum	5,529·1	5,037·4	5,036·6
Indiarubber wares	4,680·3	6,115·1	7,379·6
Paper, cardboard and wares thereof	903·4	1,249·6	1,086·8
Hides and skins	16,491·9	17,452·7	18,965·5

Exports.

Articles.	In 1,000*l.*		
	1903.	1904.	1905.
Coal, coke and other fuel	14,399·2	14,957·2	15,096·5
Tar, pitch, resin, asphalt	675·8	740·7	834·1
Earths, ores, precious metals	9,488·9	8,662·4	9,899·5

Petroleum	86·3	108	132·3
Indiarubber wares	3,144·4	3,486·5	4,616·4
Paper, cardboard and wares thereof	6,095·2	6,358·3	7,158·8
Hides and skins	7,418·3	8,322	9,548·5

New Books.

"THE GAS WORLD" ANALYSES OF ACCOUNTS OF GAS UNDERTAKINGS, 1904—5. John Allan and Co., offices of "The Gas World," 3, Ludgate Circus Buildings, London, E.C. Price 7s. 6d. net.

THIS work takes the form of a bound collection of sheets, which run from I. to IV. SHEET I. contains a tabulated account of the Gas Undertakings for 1904—5, of all the principal towns and cities in Great Britain and Ireland, and the particulars given relate to (i) Coal Carbonized; (ii) Gas made and sold; (iii) Yield of Residuals; (iv) Public Lamps; (v) Mileage of Mains; (vi) Consumers; (vii) Price of Gas; (viii) Illuminating Power; (ix) Financial Results; (x) Revenue. SHEET II. The particulars here relate to:—(i) Manufacturing Charges; (ii) Rates and Taxes; (iii) Distribution Charges; (iv) Management Charges; (v) Bad Debts; (vi) Capital Paid-up; (vii) Capital per ton and per thousand; (viii) Reserve Funds. SHEET III. *Continuation of Sheet I.* SHEET IV. *Continuation of Sheet II.*

THE CYANIDE INDUSTRY. Theoretically and Practically considered. By R. ROBINE and M. LENGLEN, both Chemical Engineers, and the latter "Laureat" of the Conservatoire Nat. des Arts et Métiers; Director of Works, &c. Translated by J. A. Le Clerc, Ph.D. With an Appendix by C. E. Munroe, Ph.D. John Wiley and Sons, New York. 1906. Price 17s. net. Chapman and Hall, Ltd., London.

8vo volume, containing 330 pages of subject matter with 25 illustrations, and followed by an appendix of patents (abstracts) filling 70 pages, and thereafter the alphabetical index. The subject matter is sub-divided as follows:—PART I. CHEMISTRY OF CYANOGEN AND ITS DERIVATIVES. (i) General Considerations; (ii) Physical and Chemical Study of Cyanogen and its Derivatives; (iii) General Properties and Methods of Determination of the Various Cyanide Compounds; (iv) Thermo-chemical Data of the Cyanide Compounds. PART II. PRESENT CONDITION OF THE CYANIDE INDUSTRY. PART III. METHODS OF MANUFACTURING CYANIDE COMPOUNDS. (i) Non-synthetic and Synthetic Processes, also Special Processes; (ii) Manufacture of Ferrocyanides; (iii) of Ferricyanides; (iv) of Sulphocyanides; (v) of Prussian Blue and various other Compounds. PART IV. USE OF CYANOGEN COMPOUNDS.

SCIENCE AND THE MANUFACTURER. By Keith Quinton. Guilbert Pitman, 85, 86 and 87, Fleet Street, London, E.C. 1906. Price 2s. net.

SMALL 8vo volume, containing 86 pages of subject matter with ten half-tone illustrations. The contents are as follows:—I. General and Preliminary. II. The Training of the Expert. III. Examples of Manufactures—(1) Colours; (2) Oils and Varnishes; (3) Metals; (4) Cements, Bricks and Roads; finally, a description of an ideal Technical Laboratory.

AN INTRODUCTION TO CHEMICAL CRYSTALLOGRAPHY. By P. GROTH. Professor of Mineralogy and Crystallography in the University of Munich. Authorised Translation by Hugh Marshall, D.Sc., F.R.S. Gurney and Jackson, London. 1906. Price 4s. net.

SMALL 8vo volume, containing 118 pages of subject matter, and an alphabetical index. There are six illustrations. The matter is classified as follows:—I. Crystal Structure and its Possible Varieties. II. Polymorphism. III. Comparison of the Crystal Structure of Chemically allied Substances (Morphotropy). IV. Isomorphism. (A) Similarity of Crystal Structure in Substances possessing Analogous Chemical Constitution; (B) Relations between Crystals and Solutions of Isomorphous Substances; (C) Isomorphous Mixtures, &c. V. Molecular Compounds. VI. Racemic and Optically Active Compounds.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows —
English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the journal depends.

Bowman, Dr. F. H., l/o Deansgate; 4, Albert Square, Manchester.

Brooke, John R., l/o Straits Trading Co.; Government Laboratory, Singapore, S.S.

Brownlie, D., l/o Heaton Chapel; Alexandria Works, Alexandria, Dumbartonshire.

Corcoran, Bryan; all communicacions to 31, Mark Lane, E.C.

Craven, John I., l/o Winthrop, Mass.; retain all communications.

Davis, V. P., l/o Naugatuck; 119, Richmond Street, Plainfield, N.J., U.S.A.

Gallivan, Frank B., l/o Third Street; 48, Wallingford Road, Boston, Mass., U.S.A.

Greenway, T. J., l/o Chillagoe; 60, Brookman's Buildings, Grenfell Street, Adelaide, S. Australia.

Hinman, B. C., l/o Trewsbury Road; 48, Sydenham Hill, Sydenham, S.E.

Hobbs, Alex. F., l/o Lowell; c/o The U.S. Finishing Co., Norwich, Conn., U.S.A.

Homfray, D., l/o Greenwich; The Ings, Misterton, near Gainsborough.

Hulley, G. D., l/o Philadelphia; c/o J. Eavenson and Sons, Delaware Avenue and Penn Street, Camden, N.J., U.S.A.

Lieber, Hugo, l/o West Broadway; 1, Platt Street, New York City, U.S.A.

McCallum, A. L., l/o Sydney, N.S.; Queen Building, Halifax, N.S., Canada, Analytical and Consulting Chemist.

MacKean, Wm.; all communications to 208, Bedford Hill, Balham, S.W.

Mersereau, Cail, l/o of East 17th Street; 181, Pearl Street, New York City, U.S.A.

Murdoch, Alex., l/o Larbert; 557, Alexandra Parade, Dennistoun, Glasgow.

Simons, Albert J., l/o New Barnet; Pontianak, Dutch West Borneo, *via* Singapore.

Toyne, Francis D.; Journals to 270, Spotland Bridge, Rochdale.

Wells, Jas. G.; Journals to Carlton Lawn, Chester Road, Stretford, Manchester.

Yetton, Thos.; all communications to 86, Bow Road, London, E.

Death.

Lease, Jos., 3, Lord Street West, Southport. April 28.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 9032. Fullerton, Hodgart and Barclay, Ltd., and Liversedge. Evaporators, heating, boiling and vacuum pans, stills and the like. April 17.

,, 9305. Szek and Schauli. Rotary and like dryers. April 20.

,, 9502. Loew. Filters.* April 23.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. Full particulars will be announced later.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council (see Journal for April 30th, p. 341) will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Eustace Carey has been nominated to the office of President under Rule 8; Dr. E. G. Love, Mr. A. Gordon Salamon, and Mr. Chas. Wightman have been nominated Vice-Presidents under Rule 8; and Dr. E. Divers, F.R.S., has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's office, at least one month before the date of the Annual General Meeting, at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

ALTERATION OF BY-LAWS.

With a view to facilitate the voting of members residing abroad, notice is hereby given, in accordance with Rule 35 of the By-laws, that the Council will propose to the forthcoming Annual General Meeting the amendment of the Society's By-laws as follows:—

1. Rule 18. (*a*) That the words "At least two months before the date of each Annual General Meeting," in the first and second lines thereof, be replaced by the words, "In the second issue of the Society's Journal for the month of April in each year."

(*b*) That the words "date of that meeting," in the fourth line thereof, be replaced by the words "Annual Meeting next ensuing."

(*c*) That the words "At least one month before the date of;" in the sixth line from the end thereof, be replaced by the words "not later than the last day of May prior to."

2. Rule 19.—That the words "at least five days before the commencement of the said meeting," in the two last lines thereof, be replaced by the words, "in the second issue of the Society's Journal for the month of May."

Death.

DR. E. J. SMALE IN THE CHAIR.

THE DETERMINATION OF BORIC ACID, ALONE AND IN THE PRESENCE OF PHOSPHORIC ACID.

By [illegible] and [illegible].

[illegible] method, depends on the formation of [illegible] over a weighed quantity of calcium oxide, [illegible] ester is decomposed and the boric acid [illegible] after ignition, is calculated by increase of [illegible].

Berzelius' method, used and recommended by Thaddeeff (2), depends on the formation of [illegible] borofluoride from the distilled trimethyl [illegible]; its accuracy is, however, found to be doubtful [illegible] the imperfect insolubility of the compound [illegible]. Other methods, such as that of Partheil and Rose (3) and that of Mylius and Meusser (4), are pronounced "unsatisfactory," "complicated" and "tedious."

This paper deals primarily with the separation of boric acid as the trimethyl compound and its subsequent gravimetric estimation as the barium salt. The first series of experiments is connected with this, the second has reference to volumetric methods of estimating boric acid in the distillate, and the last deals with the direct titration in mixtures of other acids.

1.—In order to determine, first, if boric acid is completely expelled as the trimethyl salt by distillation, quantities of from 0·5 to 1·5 grms. of boric acid (5) were placed in a retort, 250 c.c. of methyl alcohol added and the mixture distilled at a temperature of from 66° to 67° C. when it was found that after distillation at this temperature for an hour the residue in the retort contained only a small proportion of boric acid and, after one and a-half hours, none could be detected.

The estimation of the boric acid, thus expelled as the trimethyl compound, with barium chloride solution was proceeded with. Known amounts of boric acid were dissolved in methyl alcohol (6), placed in a retort, and the distillate allowed to mix with a concentrated aqueous solution of barium chloride. The trimethyl borate reacts with the water according to the equation—

$$B(OMe)_3 + 3H_2O = B(OH)_3 + 3MeOH.$$

The boric acid thus liberated reacts with the barium chloride to form barium borate and free hydrochloric acid in which the former dissolves. Caustic alkali was then added and the resulting precipitate of barium borate, $Ba(BO_2)_2$, washed with alcohol till free from all traces of chlorides, dried at 110° C. and weighed on a tared filter. The resulting weights of precipitate were in all cases too high and this was found to be due to the presence of barium hydroxide which was precipitated on concentrating the solution from filtration (6). The proceeding was then modified to obviate this, and the liberated hydrochloric acid in the reaction—

$$2B(OH)_3 + BaCl_2 = Ba(BO_2)_2 + 2HCl + 2H_2O$$

neutralised accurately by means of semi-normal sodium hydroxide with phenolphthalein as indicator. The use of this strong solution of sodium hydroxide—and also of barium chloride—was necessary to prevent the solution of part of the barium borate in water, in which it was found to be appreciably soluble. Weighing the precipitated barium salt gave results corresponding to 99·93 per cent. of the theoretical.

Being now fully satisfied with the accuracy of the method, determinations of the boric acid in pure borax were undertaken. Amounts of borax of about 1 grm. were weighed out, mixed carefully with from 20 to 25 c.c. of concentrated sulphuric acid and added to 250 c.c. of methylated spirit (6) contained in a retort. An excess of sulphuric acid was found to be necessary to prevent the reprecipitation of the salt by the alcohol. The mixture was then subjected to distillation at a temperature of from 65°—70° C. and it was found advisable to keep the bulk of the alcoholic solution approximately constant by leading into the retort from a distilling flask a fresh supply of spirit. About 30 minutes sufficed to drive over most of the boron compound, but usually it was found to be necessary to continue the distillation for longer. A period of one and a half hours was adopted above as the best time for the operation. The estimation of the boric acid was then carried out as

Wt. of borax taken.	Wt. of $Ba(BO_2)_2$.	Percentage found.
0·9738 grm.	1·1262	99·0
0·9700 ,,	1·1270	99·4
0·9384 ,,	1·0900	99·6

The presence of any appreciable comparative amount of water in the retort is to be avoided, as the trimethyl borate would then be decomposed, yielding the alcohol and boric acid, which would not distil over; the result would then be too low.

This method was further applied to mixtures containing phosphates and sulphates in addition to borates with perfectly satisfactory results.

2. *Volumetric estimation with previous distillation.*—As boric acid can be titrated with standard sodium hydroxide in the presence of glycerine, and the end-points in the formation of sodium borate indicated by phenolphthalein, several determinations were tried after decomposing the borate in alcoholic solution with sulphuric acid. The apparatus used was the same as in the previous experiments: the distillate was collected in water, made up to a litre and aliquot portions taken for titration. To each portion thus taken it was found necessary to have about one-third of the bulk of the solution glycerine[10]. The results of the titration gave 99·75 per cent. of the boron compound, this error—0·25 per cent.—being considerably less than the literature on the subject would lead one to expect.

3. *Direct volumetric estimation in the presence of phosphates and sulphates.*—A mixture of a phosphate, a sulphate[11] and a borate were treated with decinormal sulphuric acid till acid to Methyl Orange, thus setting free phosphoric and boric acids. Decinormal sodium hydroxide was then run in until the solution was neutral to Methyl Orange, which was found only to indicate the end of the formation of the sodium dihydrogen phosphate; a still further amount of alkali had to be added before the solution began to react alkaline with phenolphthalein showing that the disodium compound had been formed [12]. The boric acid not being neutralised at once in aqueous solution by alkali, glycerine was then added, and the titration of the boric acid completed. The results are given below from which the accuracy of the method may be seen:—

Amounts of $Na_2B_4O_7,10H_2O$.	Amount formed by titration as above.	Per cent.	Error.
0·2390 grm.	0·2385 grm.	99·82	0·18
0·2990 ,,	0·2986 ,,	99·85	0·15
0·3824 ,,	0·3823 ,,	99·95	0·05
	Average	99·88	0·126

An error avoided here by titrating the solution previously with the sodium hydroxide till neutral or faintly alkaline, is the quantity of alkali of necessity absorbed by the water before the first trace of alkalinity is apparent. Experiments showed this to be an appreciable amount: in the case of 50 c.c. alcohol and 50 c.c. water, 0·0016 grm. potassium hydroxide was required.

The authors intend applying these methods to the determination of boric acid in food stuffs.

(1) 1905, 809.
(2) See Gooch, Ann. Chem. J., 9, 23—33, and Montemartini Gazz. chim. ital., 26, 344—348.
(3) This J., 1896, 953.
(4) See (2) and (3).
(5) Ber., 1901, 3611.
(6) Ber., 1904, 397, and this J., 1904, 269.
(7) The composition of the boric acid employed—whether $B(OH)_3$, HBO_2 or $H_2B_4O_7$—was determined by estimating the amount of B_2O_3 contained in it. A weighed amount of boric anhydride, formed by fusing the boric acid to a clear glass, was dissolved in water and titrated against potash with phenolphthalein as indicator. A weighed amount of boric acid was also titrated against the same potash. Hence the percentage of B_2O_3 in the acid used was found. In these titrations—and all subsequent ones in the second part of this paper—25 to 30 per cent. of glycerine was used, as it is found that the neutralisation of boric acid by alkali cannot be done with any degree of accuracy except in the presence of glycerine or other polyatomic alcohol. (R. T. Thomson, this J., 1898, 432.)
(8) Ordinary methylated spirits (free from mineral oil) were found to act equally well.
(9) Pure sodium hydroxide was used, prepared from metallic sodium.
(10) See note (7). Also J. Amer. Chem. Soc., 1898, 288. The determinations were done before the above papers were noticed.
(11) The sulphate might have been omitted, as it took no part in the subsequent reaction.
(12) A strong solution of disodium hydrogen orthophosphate is slightly alkaline to phenolphthalein. Comparative experiments were made with varying amounts of a saturated solution of this salt and equal quantities of water; phenolphthalein added to each and decinormal potassium hydroxide added to the water till the shades of pink were identical:—

Phosphate solution in c.c.	Alkali required for 50 c.c. of water.
0·00	0·02 c.c.
0·50	0·06 ,,
1·00	0·08 ,,
2·00	0·09 ,,
3·00 made up	0·10 ,,
4·00 to 50 c.c.	0·11 ,,
5·00	0·12 ,,
6·00	0·12 ,,
7·00	0·12 ,,
8·00	0·12 ,,

For most solutions of this salt, therefore, a deduction of 0·1 c.c. would be the maximum correction necessary.

London Section.

Meeting held at Burlington House, on Monday, April 2nd, 1906.

MR. A. G. SALAMON IN THE CHAIR.

THE RÖSE-HERZFELD AND SULPHURIC ACID METHODS FOR THE DETERMINATION OF THE HIGHER ALCOHOLS. A CRITICISM.

BY V. H. VELEY, F.R.S.

The methods for determining the alcohols of higher molecular weight than ethyl alcohol (sometimes, though not always, generically classified as fusel) in various spirits have recently become of special importance.

The two methods adopted most officially are those of Röse-Herzfeld, originally described about 20 years ago (1) and recognised in this country, Germany and Switzerland, and the sulphuric acid method adopted in France, consequently practised in this country and officially used as a general qualitative test for the purity of all kinds of alcohol in Russia.

In the present communication it is proposed to give a brief account of various experiments made to determine the accuracy, or otherwise, of these two rival processes, and also to pass such a criticism upon each as may be considered justified by three or four years' experience.

Proportion of higher alcohols in various kinds of fusel.—If the higher alcohols be reckoned in terms of 100, the proportions of each vary within the following wide limits, according as the spirit is obtained from some kind of grain, potatoes, wine, grape skins, &c.:—

Alcohol (2).	Percentage proportion.
Primary propyl	0·1 to 6·8
Primary butyl	0·0 to 62·8
Isoprimary butyl	0·4 to 24·3
Isoprimary amyl (two)	68·8 to 99·5
Hexyl	Trace
Heptyl	Trace
Glycerol	Trace
Isobutylene glycol	Trace

In the case of spirit obtained from the same source variations are produced by different yeasts or bacteria originally present or accidentally introduced, especially Granulobacter saccharobutyricum (Beijerinck) [*Bacillus hamosus* (Migula)].

Experimental work—Preparation of control ethyl alcohol.—Ethyl alcohol, purchased from Kahlbaum as of 99·8 per cent. per volume, was purified by the method adopted by Stutzer (3), namely, by fractional distillation with soda, the only difference being that a fragment of the solid hydrate was used instead of a few drops of solution.

The first and last portions of the distillate, namely, 25 per cent., each were rejected; the middle portion of 50 per cent collected and redistilled in a similar manner. The middle portion of the second distillation was used as the control spirit. This alcohol sometimes contained traces of aldehydes when tested with Guyon-Schiff's reagent made up with acid fuchsin (sodium salt of rosaniline sulphonic acid), which appears to be more delicate than the same reagent made up with ordinary fuchsin (rosaniline hydrochloride) (4).

It is possible that, though the aldehydes in the original spirit were decomposed by the soda, traces were reformed by aerial oxidation of the alcohol vapour as observed by Ilges. If this is the case the substitution of freshly precipitated silver oxide for the soda as recommended by Winkler (5), (while the present work was in progress), would not improve matters.

Purification of higher alcohols.—The following higher alcohols were used in the course of the investigation: primary propyl, primary and isoprimary butyl, two samples of fermentation amyl (obtained from (1) grain and (2) wine) and glycerol. All the samples were purchased from Kahlbaum with the exception of the sample of amyl alcohol obtained by the fractional distillation of wine, for which I am indebted to the courtesy of Mons. Ordonneau.

All these samples, except the last, were fractionally distilled and the portions coming over at the following boiling points were used for the investigation:—

Alcohol.	B.Pt. (corr.).
Primary propyl	96·3— 97·3
Primary butyl	116·3—117·0
Isoprimary butyl	108·0—108·1
Amyl (grain)	129·5—130·2
Amyl (wine)	128·5—129·5

The glycerol (sp. gr. = 1·26) was reckoned to be of 98 per cent. strength according to the table of Gerlach (6). Standard solutions of these several alcohols were made up to contain 0·5 grm. per litre (1/2000) in control alcohol of 50 per cent. per volume, or 100 grms. higher alcohol in 100,000 c.c. absolute ethyl alcohol.

These solutions were used directly for the sulphuric acid method, but for the Röse-Herzfeld method they were diluted with the quantity of water required to reduce to 30 per cent. per volume.

Determination of sp. gr. at 15° C.—As accuracy in the determination of the specific gravity of the spirit is one of the most important factors in the Röse-Herzfeld method, the modified form of Sprengel's pyknometer and method of weighing described in a previous communication (6) were adopted.

A Bunge's short-beam balance, fitted with a telescope for reading 0·1 mgrm. was used, and the weights standardised, as against a 10 grm. weight. The temperature was recorded by a thermometer graduated to 0·1 C., the various calculations of which have been previously described (7). A difference of 0·5 mgrm in two weighings of the pyknometer corresponded to a difference in value of 0·000022 in specific gravity of a 30 per cent. alcohol solution.

Calibration of the Röse-Herzfeld apparatus.—Each apparatus used was calibrated for every 0·2 c.c. by dropping in distilled water from a pipette, which delivered this volume of water at 15° C., and tables of corrections drawn up. Since the apparatus, as usually made, is graduated to 0·02 c.c., there might be an error of reading of 0·01 c.c., which corresponds to 0·022 per cent. fusel = 22 parts per 100,000, according to the table of Sell (8).

The process.—It is not, of course, necessary to describe the process, which is given more or less fully in various manuals, but it may be worth while to deal with certain precautions and to add a few personal observations.

(1) *The chloroform.*—This was sheltered from light by keeping the containing bottle in a black paper mantle; even though each separate sample may be tested in a control experiment, yet this is a very necessary precaution, as it is well known that chloroform, as other chloro-derivatives of hydrocarbons, decomposes slightly and slowly even in diffuse sunlight with liberation of hydrochloric acid. The result of using such acid containing chloroform would be that, besides the sulphuric acid purposely added (1 c.c. sp. gr. = 1·268, 35·5 per cent. H_2SO_4 at 15/15), there would be extracted by the aqueous spirit the hydrochloric acid, which would affect the rise of the chloroform column.

Though the effect of hydrochloric acid on the mutual solubility of chloroform and water has not apparently been a subject of investigation, yet it would follow as a logical consequence of the work of Wright (9) and Schreinemaker (10) on the mutual solubilities of chloroform, water and acetic acid and of chloroform, water and alcohol that an error in the determination would be introduced. Further, it has been shown by Gelsthait (11) that the presence even of carbonic acid, as in the spirit manufactured from maize, does affect the rise of the chloroform, and hence, the determination.

(2) *Method of working.*—It is not, of course, necessary to describe the process of cleansing with concentrated sulphuric acid and other details, but it may be worth while to put on record two observations:—

Firstly. If, after shaking, the chloroform is allowed to drop very slowly from the upper to the lower bulb, a more distinct line of demarcation between the chloroform and aqueous layer is obtained.

Secondly. My observations are in accordance with those of Grünheit (12) that, after the manipulation has been completed the chloroform slowly contracts, sometimes requiring an hour before a constant level is reached; this is more especially the case for distillates obtained from spirits of commerce, brandy, whisky, &c.

Disadvantage of the method.—This lies in the fact that if b is the rise of the chloroform in the blank experiment with the control spirit, and a, the rise with the fusel containing spirit, then the difference $a-b$, the basis of the determination is in most cases very small compared with a and b. In the case of an atomic weight determination this disadvantage would be considered fatal.

Results obtained with various higher alcohols.—It has been shown that the fusel obtained from various sources gives approximately the same value per unit weight fusel per unit volume alcohol, if the results are expressed in terms of amyl alcohol, the predominating substance. As above stated, it has been thought desirable to examine each of the higher alcohols separately, and the results are given in the table as under in column (I.) the alcohol used, in (II.) the difference of sp. gr. from 0·996575 in 10^{-6}, in (III.) the value of $(a-b)\times 2·22\times 1000$, namely, grammes per 100,000 absolute alcohol found, in (IV.) the amounts purposely introduced. The difference between the values of (III.) and (IV.) is the error:—

I.	II.	III.	IV.
Primary propyl	+25	134·0	100·0
do. butyl	—27	196·0	100·0
do. do.	—45	222·0	200·0
Isoprimary butyl	—25	89·0	100·0
do. do.	—45	177·5	200·0
Amyl (from grain)	—5	115·0	100·0
do. (from wine)	+5	127·0	100·0
Glycerol	—5	94·4	100·0

As a possible error in reading by estimation of 0·01 c.c. would account for a difference of 22 in the values of III. and IV., it appears that all the several higher alcohols give the same value in the Röse-Herzfeld method. The errors beyond the number 22 might be due to various causes, such as variation of temperature, impurity in

alcohol not eliminated, &c., all acting in the same direction.

But, if all the necessary, but tedious, precautions are adopted, this method may be regarded as accurate not only for commercial purposes, but also for legal jurisdiction.

Preparation of distillates obtained from commercial spirits.—My practice has been to heat for one hour the distillates obtained from brandy, &c. (50 or 100 c.c. taken) with a fragment of solid caustic soda in a flask fitted with an inverted condenser, whereby the aldehydes are destroyed by resinification and the esters by saponification. The liquid is then subsequently distilled almost to dryness.

Though the process has the disadvantage, whatever method be subsequently employed, that the higher alcohols derived from the esters of more complex molecular weight come over in the distillate and the true value of such alcohols is raised accordingly. On the other hand, if the sulphuric acid process is adopted, and the aldehydes only are destroyed by heating with *m*-phenylene diamine (an unsatisfactory method), or preferably with aniline phosphate [13], the less complex esters act as matter in the way, thus tending to lower the value of the higher alcohols, while the more complex esters (amyl acetate for example) themselves produce a coloration, which tend to raise the value.

My experience has been that more information is obtained by adopting the soda method especially for the detection of certain artificial essences used for brandies. For when the sulphuric acid method is subsequently applied, a bright red (instead of a yellow) coloration is produced, indicating the probable presence of such substances as vanillin or Peru-balsam. If in such cases the Röse-Herzfeld process is also applied, the value for the higher alcohols is far too low, and the chloroform is rendered milky.

The sulphuric acid process.—It is not, of course, necessary to describe this process, which has been so widely adopted; it is only necessary to deal with its defects, and to describe certain modifications, which, in my experience, have proved advantageous.

The conditions and nature of the reaction.—So far as I am aware no interpretation has been given of the reaction, nor why it ever begins. Of the higher alcohols it appears to be characteristic, under usual conditions, of those which contain an isoprimary group CHR_2, and my observations are in accordance with those of others, that no coloration is produced with ethyl, primary propyl and butyl alcohols, however long the process of heating be protracted.

But, further, so far as my experiments have gone, it would appear to be quite doubtful if any reaction would take place even with isoprimary butyl alcohol regarded as the most susceptible, and consequently taken as the type, if the alcohol and the sulphuric acid are pure, and the containing vessel quite clean. The following details will serve to illustrate this point. A small soda-glass stoppered bottle was thoroughly soaked out by a sample of Merck's special sulphuric acid (sp. gr. 15/4 = 1.84161) (found to be free from organic matter, sulphurous, hydrochloric, nitric and nitrous acid, but to contain an inappreciable trace of ammonia), firstly, by heating for some hours at 100°, and, subsequently, by allowing to stand for several days. The acid was then poured out; 20 c.c. of a standard, 1/2000 solution of isoprimary butyl alcohol (freshly distilled) introduced, and then 20 c.c. of the same sample of sulphuric acid added slowly, the bottle being immersed in ice-cold water. When this mixture was heated at 110° no coloration was developed for 30 minutes, and at the end of an hour only a slight coloration ensued. On repetition of such an experiment, the greater the care bestowed on the preliminary cleansing process, the longer the time required for the development of the colour, and conversely the less the care, and the less pure the sample of sulphuric acid, the more rapid the development of the colour.

Of course, these results are in accordance with numerous observations upon other reactions, which have proved that no chemical change takes place between two substances only. But until the nature of the impurities has been ascertained, which start the reaction between the acid and the alcohol, there will always be an element of uncertainty in the application of the method.

Effect of temperature.—It has been objected that the depth of tint varies with the temperature [14]. This is, of course, true, and my experience, doubtless confirmed by others, has been to the effect that a difference of 2°—3°, other conditions being the same, causes a considerable difference in tint. But, as all chemical changes vary with temperature, this objection can hardly be regarded as serious.

Isoprimary butyl alcohol as the standard.—It has been objected that a solution of this alcohol is used as the comparative standard, and the results are given in terms of it, but with the exception of spirits obtained from beet and grape skins, the proportion of this alcohol is quite insignificant, and may amount to as little as 0·5 per cent. It has been further stated [15] that the tint produced by the fermentation amyl alcohols is, in round figures, 6/10 of that produced by isoprimary butyl alcohol. In an experiment two solutions were made up according to the usual details, in the proportions of (1) 100 amyl alcohol and (2) 60 isoprimary butyl and 40 ethyl alcohol; the tints produced were in the ratio of 119:120, or practically 1:1, but it was found that this ratio only held good under these conditions.

It has been suggested that an amyl rather than an isoprimary butyl alcohol standard should be adopted; this would appear to be more rational, but there is the disadvantage that, whereas a solution containing 125 mgrms. per litre of isobutyl alcohol produces a quite inappreciable coloration (a result personally confirmed), a solution containing 250 mgrms. per litre of fermentation amyl alcohol would also produce an inappreciable coloration (a result also confirmed).

A determination upon this basis would possess an order of accuracy much less than of the Röze-Herzfeld method. It is probably best to make the determination in terms of isoprimary butyl alcohol, and then multiply by the factor 10/6 to convert into terms of amyl alcohol.

However this may be, it is somewhat difficult to understand the degree of assurance with which the results of analyses are put down to five figures, when an error of 5 per cent. in a tintometer reading, which is possible for the same individual, might in a genuine spirit of commerce cause an error of 2 to 8 units in the third figure.

The following sentence from Girard and Cuniasse's Manual (page 244) appears to be quite unintelligible:—"Enfin le dosage colorimetrique des alcools superieurs au moyen de l'acide sulfurique est un procédé conventionnel auquel on ne saurait demandé des *chiffres absolus, mais des données analytiques exactes constantes et comparables.*"

Curve of correction.—If C,*c* be the concentration mgrms.-litre) of an isobutyl solution (C,*c*) and H,*h* be the heights of column in the tintometer (H,*h*), then it appears from the results of former observers $Ch/cH = a$ variable, or in other words the heights of columns (depths of tint) are not directly inversely proportional to the respective concentrations as in certain other colour reactions, such as Nessler's test for ammonia, *m-phenylene* diamine for nitrous acid, or aniline acetate for furfural. A curve of correction has therefore been drawn out (Girard and Cuniasse Manual, page 204). It, therefore, appears desirable to ascertain the relation between the values of the abscissæ, *y*, (teneur realle) and those of the ordinates, *x* (teneur apparente) [16]. The most natural assumption to make is that the variation of *y* per unit of *y* is in a fixed ratio to the variation of *x* per unit of *x*, namely:—

(1) $$dy/dx = ky/x.$$

This on integration gives

(2) $$\log. y = b \log. x + a.$$

From the numbers given $a = 0{\cdot}28$, $b = 0{\cdot}6$, or

3 $$\log. y/100 = 0{\cdot}6 \log. x/100 + 0{\cdot}28.$$

The values of *x* corrected in terms of *y* given and of *y* corrected in terms of *x* given are set forth in the following table, which may be found useful, and any intermediate value may be duly corrected by equation (3):—

Milligrams per litre.

Values of y (x given).		Values of x (y given).	
Found.	Calculated.	Found.	Calculated.
200	240	70	22
300	270	180	210
400	390	330	340
500	500	500	500
600	601	680	676
700	706	890	879
800	803	1100	1090
900	897	1320	1330
1000	1005	1600	1585

Hence it would appear that from the co-ordinates of the point $y=300$, $x=100$, the curve is regular.

The curve from the origin to this point need hardly be considered, as on the one hand effected by the limit of delicacy of the reaction, and on the other by some induction period between the reacting substances.

Method of working.—As the sulphuric acid process has, *inter alia*, formed the basis of contracts between vendor and purchaser, and as valuable information is, notwithstanding its defects, obtained by its application, I would briefly describe slight modifications which I have found useful. The processes of heating the mixture in equal volumes of the sulphuric acid and alcohol solution, either (1) till it begins to boil, or (2) in an open flask in a calcium chloride or other bath, are both more or less unsatisfactory, as a loss is likely to occur by evolution of vapour of the higher alcohol before it is attacked by the sulphuric acid. To avoid this loss I have been accustomed to use glass-stoppered bottles of about 50 c.c. capacity, and during the heating operation the stopper is kept tied down. I have further found that a bath of saturated ammonium chloride solution, provided with a constant water-level appparatus, is very convenient; a constant temperature of 100°—110° can readily be maintained. The process of cleansing the bottles with concentrated sulphuric acid is described above, and my custom has been to soak out the bottles for at least a week before using them for a determination. Cleansing by nitric in addition to sulphuric acid, as recommended by some writers, is a source of danger, and even distilled water, unless freshly prepared, may introduce error.

Form of tintometer.—As a sequence to the criticism of the sulphuric acid method, I may possibly be allowed to remark that a form of tintometer, which can be adjusted suitably for all eyes remains as yet to be devised. The simple form of two tubes, one with a fixed and the other with an adjustable column interposed between two mirrors, though convenient for rapid working, possesses the disadvantage that two coloured discs appear at a distance apart on the upper mirror, and an observer insensibly looks at each disc successively with the same eye, and not one disc with one eye simultaneously. Even if this is the case, the two eyes of the same person are seldom, if ever, physiologically the same as regards appreciation of colour (17). The Duboscq form possesses the advantage that the two discs are viewed simultaneously by one eye; but neither of these two forms permit the interposition of suitable coloured screens. Donnan's (18) tintometer possesses this advantage, and, according to my experience, gives concordant results though with considerable labour; on the other hand, it appears to possess two disadvantages: (1) Equality of tint does not correspond to equality of height (though a table of corrections can be drawn up), and (2) a small inner disc is brought to the same tint as a much larger outer disc, and consequently the eye becomes soon confused and tired.

I have tried various observers with the same pair of coloured liquids and the same illumination (*viz.*, 16-candle electric lamp with silvered back at 3 ft.) with invariably the same result, some being more and others less rapidly fatigued.

But, as stated above, in this tintometer a coloured screen in the form of a suitable solution can be introduced, so that if an observer's eye is not very sensitive to differences of tint of one colour, its complimentary colour can either be produced, or certain rays may be eliminated and tints thereby produced to which the observer's eye may be more sensitive.

Thus, in my case, I have found that not only is my right eye more sensitive than the left, but both eyes are more sensitive to variations in shades of green, than in shades of yellow. The interposition of a screen made of a dilute ammoniacal solution of copper sulphate, in the sulphuric acid higher-alcohol method, whereby a green tint is produced renders the results more concordant, at least, for myself.

It might not be wholly out of place to remark that as regards colorimetric observations, the personal element is of a two-fold nature, namely, that of one individual with another, and that of the same individual with himself, according to his state of health.

If facts such as these are considered, so much capital would not be made, especially by ill-informed persons, of variations in the results obtained by two observers, in an analysis of the same sample of spirit, which, in the case of the aldehydes and higher alcohols, may amount to a few parts per 100,000, and in the case of furfural to a few parts per 1,000,000.

Such differences are generally wholly immaterial as regards the main issue, though it is possible that even these differences might be reduced if some standard illumination for tintometer readings could be agreed upon.

Finally, it is hoped that the results and observations detailed in this communication may prove of interest; though possibly they are of a general character, yet they are the outcome of three to four years' experience; my object has been to criticise methods rather than to add to the accumulation of analyses.

Discussion.

Dr. J. T. Hewitt said all who had anything to do with spirit analysis had to pay more attention to estimations of this description than they desired. He was much interested in Dr. Veley's remark, that the more care that was taken in the estimation of the higher alcohols by the colorimetric process, the worse the result. This might, perhaps explain some of his own results. He certainly found that by the colorimetric process he could not get results to agree with those of other chemists, though results obtained by the Allen-Marquardt process usually agreed better. It certainly was a very troublesome matter to know what to do in this case. He thought Dr. Veley had put his finger on the whole thing—it depended on the care taken. Where one chemist was satisfied with guaranteed pure isobutyl alcohol, another might take the trouble to rectify it before using it. He himself took the precaution of rectifying it twice over, and even under those conditions, he found he still got a coloration with strong sulphuric acid. That might

be due, however, to "his favourite wash-bottle." He would have been glad if Dr. Veley had compared the results of this method with the Allen-Marquardt process. He was personally a convert to the latter process, because it was possible to get concordant results, and the process did seem to be based on scientific principles. Dr. Veley got very good results with the Röse-Herzfeld process when he extracted the higher alcohols from an alcohol to which he had added higher alcohols in certain proportions. But suppose he tried the experiment of taking not merely alcohol, but alcohol to which he had added higher alcohols and the other normal secondary products of spirits, would his results then tally? The whole idea underlying the application of this process seemed to him to be wrong; it could not be only the higher alcohols which were extracted. Even if the esters were saponified other substances present in spirits remained which could not be classed amongst the secondary products which go to make up the coefficient of which they heard so much about at present. There were, undoubtedly, a great many spirits, certain Irish whiskies, which might be boiled for a long time with caustic soda, and distilled until there was reason to think that all the aldehydes and esters, and all the acids were gone, and there ought to be nothing but alcohols according to the tables in the books; yet substances were present which did not tally with anything which came under the heading of higher alcohols. These substances must be extracted by chloroform to a certain extent, and certainly he thought the Allen-Marquardt process seemed more promising.

Dr. P. Schidrowitz said in his opinion both these processes were radically wrong. He was surprised that Dr. Veley had made no reference to the only process which was based on accurate scientific chemical methods; a process by which the chemist did obtain chemical substances which were measured by ordinary chemical means, namely, the Allen-Marquardt oxydation process. With regard to the Röse-Herzfeld method, he was, of course, aware of the claims put forward for it in Germany, and he had himself found that when they used the pure higher alcohols in this method with very great care, good results were obtainable. But he had also found, and pointed out in a paper before that Society in 1902, that working with commercial spirits, the process gave entirely erroneous results; in fact occasionally actually negative results could be obtained, and the chloroform column, instead of rising, was depressed. This was possible because, as Windisch, in 1889, pointed out, there were certain substances which did have this effect on the chloroform column. He should like, moreover, to point out that this process which was at one time in use, in the Government Laboratory in America, had now been abandoned. Dr. Wiley, the Chief of the Laboratory, himself informed him they had had to abandon it as useless, and were now using the Allen-Marquardt. He did not know what process was officially used in this country, but he should doubt if it was the Röse-Herzfeld, because, on the last occasion on which any official evidence was given, namely, that before the Spirits Committee in 1901, the results given by Dr. Bell were based on a purely chemical oxidation method. He had also a communication from the gentleman who was conducting a series of investigations for the Indian Government on the spirit question, who had tried all these methods on a large number of samples, and had to abandon them all except the Allen-Marquardt. He (Dr. Schidrowitz) had during the last few years made a very large number of experiments in conjunction with his colleague Mr. Kaye, on the various processes for estimating higher alcohols, and their application in practice, and had come to the conclusion that the only process which gave reliable results was the Allen-Marquardt oxydation process, carried out on the lines of the modification described by him before that Society in 1902. Coming to the colorimetric method, he cordially agreed with everything Dr. Veley had said and more than agreed. As he had pointed out on a number of occasions for several years past, this process, both in principle and in practice, was a bad one.

Mr. A. C. Chapman said for a good many years he had had a considerable experience in the estimation of the higher alcohols in spirituous liquids; in fact, long before it became a matter of almost everyday procedure. He had tried all the more important methods proposed for the estimation of these constituents, including the Röse-Herzfeld, the colorimetric method, the physical methods based on surface tension, the original method of Marquardt, and later, and more particularly, the process to which Dr. Hewitt and Dr. Schidrowitz had referred, the Allen-Marquardt method. He was bound to say that he agreed with every word those speakers had used. The Röse-Herzfeld was bad both in principle and practice; the results were exceedingly uncertain, and, as Dr. Veley himself had pointed out, it was objectionable, inasmuch as the difference, which was the quantity measured, was exceedingly small compared with the large volume of solution with which one had to deal. The colorimetric process was, if anything, worse, at any rate it had proved so in his hands. He had finally come to regard the Allen-Marquardt process as the only reliable one at present existing for the estimation of these higher alcohols. In the first place, it was based on definite chemical reactions, and one had it in one's power, moreover, to ascertain to some extent the degree of accuracy of one's results, because one could roughly ascertain that the bodies which one had extracted were really the higher alcohols. It was a perfectly simple extension of the process, and one which many analysts made use of to convert the distilled acids into barium salts, and then ascertain the mean molecular weight of the fatty acids, thus obtaining an insight into the true nature of the bodies extracted by the carbon tetrachloride. Other processes were purely arbitrary. It was quite possible that one worker making use of the Röse-Herzfeld, or the colorimetric process, might get concordant results, but, as had been pointed out, it was exceedingly difficult to obtain results which would agree with those obtained by somebody else. He did not think the same objection applied in anything like the same degree to the Allen-Marquardt process, for he had had the opportunity of comparing his own results with those obtained by some of his colleagues, and had been struck with the comparatively small differences in the numbers obtained. With the other processes, more especially those to which Dr. Veley had referred, nothing like the same amount of concordance could be obtained. The paper would be valuable as a guide to many who still persisted in using these processes, but at the same time it would be well if such could be converted to the Allen-Marquardt process.

Dr. Veley, in reply, said the speakers who had dealt with this paper had, perhaps, misunderstood slightly the purpose of the discussion of these processes. It was his endeavour to point out that the first process was unsatisfactory, and the second more unsatisfactory. But, like many other unsatisfactory methods, they had the official sanction of certain European Governments; and it would appear, therefore, that it would be best to peaceably persuade the Governments, or the persons in charge of official laboratories, that these processes were unsatisfactory. The Röse-Herzfeld method, for example, had the merit of being described in an English Blue Book, and certainly he believed that the Somerset House laboratories had still a certain appreciation of the process. He was aware, of course, that there were processes which were more accurate, but his whole purpose was to criticise these two which had the most official sanction.

Dr. Schidrowitz said if Dr. Veley referred to the Bonded Spirit Blue Book when he said the Röse-Herzfeld method was described in it, it was described there only in order to be blamed.

New England Section.

Meeting held at Boston, on Friday, April 6th, 1906.

MR. HENRY HOWARD IN THE CHAIR.

THE SUBSTITUTION OF PYRITES FOR BRIMSTONE IN THE MANUFACTURE OF SULPHITE PULP.

BY FREDERIC J. FALDING.

Technical sulphur dioxide, known as "burner gas," is prepared by the combustion in air of some raw material which consists largely of sulphur. Such materials are brimstone, which is sometimes almost pure sulphur; pyrites; various other metallic sulphides, in some of which, such as copper or zinc sulphides, the sulphur content is only of secondary value; together with one or two other materials, such as "spent oxides" and sulphuretted hydrogen, which are in the nature of waste products from other industries. As air contains about 21 per cent. of oxygen, it follows that sulphur when burned in air can theoretically produce a burner gas consisting of 21 per cent. of sulphur dioxide and 79 per cent. of nitrogen. This would imply perfect combustion in pure air, which is not a technical condition. When brimstone is used under the best conditions, a burner gas containing as high as from 18—20 per cent. of sulphur dioxide can be obtained. Burner gas, produced from pure pyrites, can only contain 16 per cent. of sulphur dioxide. In practice it will only contain 11 to 12 per cent., although, with proper precautions, suitable combustion furnaces, and favourable conditions, as high as 14 per cent. can be obtained.

Generally speaking, the range of percentages of sulphur dioxide contained in burner gas, where high percentage is desirable, may be stated to be 14 to 18 per cent. when prepared from brimstone, and 10 to 14 per cent. when prepared from pyrites. If an average is taken of these percentages, or comparing them as 16—12, it is evident that to obtain equal volumes of sulphur dioxide, it will be necessary to use one-third more burner gas when it is made from pyrites or metallic sulphides than when it is made from brimstone.

Furthermore, the preparation of burner gas from pyrites or metallic sulphides results in a gas containing various impurities, such as arsenic, selenium, &c., some of them injurious in the technical processes for which burner gas is used, and more or less difficult to eliminate. If, therefore, it is desired to prepare a pure burner gas containing as high a percentage of sulphur dioxide as possible, it would appear that brimstone is best suited to the purpose, and one would expect to find brimstone universally employed by manufacturers who use this gas. The contrary is, however, the case. Only a comparatively small and decreasing proportion of burner gas is made from brimstone, and gas so made is largely confined to the sulphite pulp industry of the United States.

The volume of "burner gas" used throughout the civilised world is enormous, yet its history is comparatively recent, the different industries in which it is directly employed are comparatively few, and the principles governing its technology and commercial production, whilst not very complicated, are not generally so well understood as they might be with advantage to the manufacturing processes in which it is employed.

The sulphuric acid and sulphite pulp industries use nearly the whole of this burner gas. A small amount is used for bleaching processes, and some in various metallurgical processes. The requirements of these two industries as to the mechanical or physical and chemical conditions of the burner gas are also practically identical. Its purity is as advantageous to the sulphite pulp maker as it is to the sulphuric acid manufacturer.

Large quantities of sulphuric acid are made for fertiliser purposes, of course, where no particular purity is called for, but, on the other hand, commercial sulphuric acid must be pure enough to be used in the preparation of many foodstuffs, and for other purposes calling for a high degree of purity. For the manufacture of sulphuric acid by the contact process, this burner gas must contain no impurity other than nitrogen, save possibly some carbon dioxide, discoverable by either chemical or optical test. Arsenic, so constant an impurity in the burner gas made from pyrites, and the most difficult impurity to remove from the gas, is an absolute "poison" to the contact mass, rendering it inert almost immediately, even in exceedingly small quantities. It is probably not well known that the very large quantity of sulphuric acid used (probably about 150,000 tons yearly of 60° B.) in the United States, in the steel and iron industry for pickling sheets, wire, &c., previous to galvanising or tinning, must contain less than 0·002 per cent. of arsenic.

The strength or percentage content of sulphur dioxide contained in the burner gas is also, within certain limits, of equal importance to both the sulphite pulp and the sulphuric acid manufacturer. A low tenor of sulphur dioxide in the burner gas means a larger investment in plant, larger apparatus, and an increased manufacturing cost to both industries.
